EUROPEAN HEMATOLOGY ASSOCIATION

haematologica

Journal of the European Hematology Association
Owned & published by the Ferrata Storti Foundation

Word of Welcome

On behalf of the EHA Board and the Scientific Program Committee we are pleased to introduce to you this year's Abstract Program. The richness of the program is a testament to EHA's spirit: unity through diversity.

The Scientific Program Committee has compiled an exciting program of Simultaneous Oral and Poster Sessions from close to 2500 submitted abstracts representing all fields of hematology. For the second year, a number of presenters will have the opportunity to pitch their abstract. These Poster pitches are an exciting opportunity to promote basic science and research, and to invite delegates to the poster walks.

The six Best Abstracts will be presented during the Presidential Symposium on Friday afternoon. This will be a session not to miss. During this plenary session EHA is also awarding, for the first time, the best abstracts by trainees in four categories in basic and clinical hematology research. These awardees and the travel grant winners can be found on the next page. YoungEHA are the future of hematology!

The late breaking abstract submission is an integral part of the scientific program. The late breaking submission is intended for abstracts with "hot" data that were not available by the time of the regular submission deadline. Only few abstracts, with the most exciting results are selected for a presentation in the Late Breaking Oral Session on Sunday morning.

A selection of abstracts will be presented during the regular Poster Walks. The Poster Session consists of two parts: the Poster Walk and dedicated Poster Browsing Time. This setup guarantees sufficient time for discussion of the important research presented, so look out for the Poster Walk Moderators in their red baseball caps! There will also be E-posters available on the E-poster screens, for which a specific time is allocated during the Poster Browsing Time at the end of each Walk. The Simultaneous Oral Sessions are spread over three days (Friday to Sunday) providing you with ample opportunity to attend a number of these important sessions.

All posters can be viewed on the E-poster screens from Friday morning to Saturday evening. All the abstracts are also available on the EHA Learning Center, for which you have complimentary access after the congress: learningcenter.ehaweb.org.

On behalf of the EHA Board, the committees and all the people involved in this year's EHA Congress, we thank you for coming to Madrid and wish you a great meeting.

YoungEHA Best Abstract Awards

One of the primary missions of the European Hematology Association is to support young hematology clinicians and researchers. This year we are proud to announce the launching of the YoungEHA Best Abstract Awards. These will be awarded to the highest ranking abstracts in the following four categories: Clinicians or medical students training for a PhD degree, PhD research students, postdoctoral fellows and clinical hematology trainees. We are honored that these outstanding YoungEHA trainees will be presenting during the EHA congress – they are the future of Hematology!

EUROPEAN HEMATOLOGY ASSOCIATION

haematologica

Journal of the European Hematology Association
Owned & published by the Ferrata Storti Foundation

Information for readers, authors and subscribers

Haematologica (print edition, pISSN 0390-6078, eISSN 1592-8721) publishes peer-reviewed papers on all areas of experimental and clinical hematology. The journal is owned by a non-profit organization, the Ferrata Storti Foundation, and serves the scientific community following the recommendations of the World Association of Medical Editors (www.wame.org) and the International Committee of Medical Journal Editors (www.icmje.org).

Haematologica publishes editorials, research articles, review articles, guideline articles and letters. Manuscripts should be prepared according to our guidelines (www.haematologica.org/information-for-authors), and the Uniform Requirements for Manuscripts Submitted to Biomedical Journals, prepared by the International Committee of Medical Journal Editors (www.icmje.org).

Manuscripts should be submitted online at http://www.haematologica.org/.

Conflict of interests. According to the International Committee of Medical Journal Editors (http://www.icmje.org/#conflicts), "Public trust in the peer review process and the credibility of published articles depend in part on how well conflict of interest is handled during writing, peer review, and editorial decision making". The ad hoc journal's policy is reported in detail online (www.haematologica.org/content/policies).

Transfer of Copyright and Permission to Reproduce Parts of Published Papers. Authors will grant copyright of their articles to the Ferrata Storti Foundation. No formal permission will be required to reproduce parts (tables or illustrations) of published papers, provided the source is quoted appropriately and reproduction has no commercial intent. Reproductions with commercial intent will require written permission and payment of royalties.

Detailed information about subscriptions is available online at www.haematologica.org. Haematologica is an open access journal. Access to the online journal is free. Use of the Haematologica App (available on the App Store and on Google Play) is free.
For subscriptions to the printed issue of the journal, please contact: Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, E-mail: info@haematologica.org).

Rates of the International edition for the year 2017 are as following:

	Institutional	*Personal*
Print edition	*Euro 500*	*Euro 150*

Advertisements. Contact the Advertising Manager, Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, e-mail: marketing@haematologica.org).

Disclaimer. Whilst every effort is made by the publishers and the editorial board to see that no inaccurate or misleading data, opinion or statement appears in this journal, they wish to make it clear that the data and opinions appearing in the articles or advertisements herein are the responsibility of the contributor or advisor concerned. Accordingly, the publisher, the editorial board and their respective employees, officers and agents accept no liability whatsoever for the consequences of any inaccurate or misleading data, opinion or statement. Whilst all due care is taken to ensure that drug doses and other quantities are presented accurately, readers are advised that new methods and techniques involving drug usage, and described within this journal, should only be followed in conjunction with the drug manufacturer's own published literature.

NEXT GENERATION SEQUENCING METHODOLOGY FOR DETERMINING CYTOGENETIC RISK STATUS IN THE DARATUMUMAB PHASE 3 CASTOR AND POLLUX STUDIES IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA

C. Chiu[1,*], D. Soong[1], I. Spicka[2], M. Beksac[3], M. Schaffer[1], J. Schecter[4], N. J. Bahlis[5], M. A. Dimopoulos[6]
[1]Janssen Research & Development, LLC, Spring House, PA, United States, [2]First Faculty of Medicine, Charles University, Prague, Czech Republic, [3]Ankara University, Ankara, Turkey, [4]Janssen Research & Development, LLC, Raritan, NJ, United States, [5]Tom Baker Cancer Center, University of Calgary, Calgary, Alberta, Canada, [6]National and Kapodistrian University of Athens, Athens, Greece

Background: Cytogenetic risk status in multiple myeloma (MM) studies is traditionally determined by using fluorescence *in situ* hybridization (FISH) or karyotyping to assess chromosomal abnormalities. However, these technologies have limited resolution and a narrow target range, and reproducible interpretation may be confounded by inter-laboratory variation.
Aims: To describe the NGS methodology used to determine cytogenetic risk status in the daratumumab phase 3 CASTOR and POLLUX studies in RRMM.
Methods: Bone marrow aspirates were collected at screening and assessed centrally via NGS. Whole exome sequencing (exome-seq) and RNA sequencing (RNA-seq) was performed using the Illumina HiSeq platform to identify the presence or absence of defined risk markers: t(4;14), t(14;16), or del17p. The use of RNA-seq allowed for investigation of chromosomal translocations in expressed genomic locations at a higher resolution than FISH, and exome-seq data was used to derive the copy number status in coding regions across the genome. RNA-seq was performed using total RNA and rRNA removal to capture translocations involving coding and intronic regions. Translocation calls were made using two fusion callers, and gene expression was quantified to allow for evaluation of genes associated with translocation events. For t(4;14) translocations, the detected events involved RNA-seq reads fused between IgH and WHSC1 or FGFR3. For t(14;16), the detected translocations involved IgH and WWOX. Manual inspection of patients with t(4;14) showed higher WHSC1 or FGFR3 expression, whereas t(14;16) patients showed higher MAF and CCND2 expression. For del17p detection, exome data of each tumor was compared against 100 peripheral blood mononuclear cell (PBMC) control samples from CASTOR and POLLUX studies. Copy number variation data from two callers were combined to utilize information on relative read depth, systematic biases (observed in pooled normal controls), as well as SNP allele frequency (indicative of loss of heterozygosity events). A del17p event was detected when >50% of the 17p region was deleted.
Results: Based on the RNA-Seq and exome results, cytogenetic risk status in the CASTOR and POLLUX studies was defined as high risk with having either t(4;14), t(14;16), or del17p, and standard risk with the confirmed absence of these molecular abnormalities. Comparisons of NGS with FISH showed high concordance for t(4;14), t(14;16), and del17p in both studies (Table 1).

Table 1.

Concordance rate between FISH and NGS	POLLUX	CASTOR
t(4;14)	96%	92%
t(14;16)	98%	97%
del17p	88%	90%

PFS analyses investigating differences between treatment groups and between risk groups using FISH-derived risk and NGS-derived risk showed consistent results between FISH and NGS, with improvements in PFS being associated with the addition of daratumumab to standard-of-care regimens in both high- and standard-risk subgroups (Figure 1).
Summary/Conclusions: These studies represent the first, comprehensive use of NGS in global phase 3 clinical trials in RRMM. The NGS methodology accurately identified the presence of defined risk populations t(4;14), t(14;16), and del17p and showed good concordance with FISH. As FISH was performed locally with different probes and pathologists, the high degree of concordance between FISH and NGS is notable and supports the use of NGS for determining cytogenetic risk in patients with RRMM. The utility of NGS in these clinical studies extends far beyond the detection of cytogenetic abnormalities and additional analysis are planned to interrogate these datasets in the identification of novel biomarkers.

Background: Daratumumab (D) is a human CD38-targeting monoclonal antibody that exerts its antimyeloma activity through both direct (on-tumor) and indirect (immunomodulatory) mechanisms of action. Two randomized phase 3 trials in patients with relapsed or refractory multiple myeloma (RRMM) demonstrated that combining D with the standard-of-care regimens lenalidomide +dexamethasone (Rd, POLLUX) or bortezomib +dexamethasone (Vd, CASTOR)

significantly improved progression-free survival (PFS) and achieved higher overall response rates (ORRs) compared with the respective standard-of-care regimen alone (Dimopoulos MA *et al.*, *N Engl J Med* 2016;375(14):1319-1331; Palumbo A *et al.*, *N Engl J Med* 2016;375(8):754-766.). Due to its novel mechanisms of action, addition of D to standard-of-care regimens may benefit RRMM patients who have poor prognoses resulting from high-risk cytogenetic abnormalities.

Aims: To examine the efficacy of DRd and DVd in RRMM patients with standard or high cytogenetic risk status.

Methods: Bone marrow aspirates were collected at screening visits from 311/569 patients from POLLUX and from 353/498 patients from CASTOR, and cytogenetic abnormalities were detected via next-generation sequencing (NGS). Patients were considered to be of high cytogenetic risk status if they had ≥1 of the following abnormalities: t(4;14), t(14;16), or del17p; patients were considered to be of standard cytogenetic risk if they lacked these abnormalities. Minimal residual disease (MRD) was assessed at suspected complete response (CR) at 3 sensitivity thresholds (10^{-4}, 10^{-5}, and 10^{-6}) using the ClonoSEQ™ NGS-based assay (Adaptive Biotechnologies, Seattle, WA). Efficacy analyses included PFS, ORR, and MRD-negative rates.

Results: For POLLUX, the median follow-up was 17.3 months. Treating high-risk patients with DRd significantly prolonged median PFS *vs* Rd (top panel Figure 1) and numerically increased ORR (85% *vs* 67%; *P*=0.14). Responses to DRd *vs* Rd included CR or better in 33% *vs* 6% of these patients, and very good partial responses (VGPR) or better in 63% *vs* 31%. In standard-risk patients, DRd *vs* Rd also resulted in significant improvements in median PFS (Figure 1) as well as ORR (95% *vs* 82%; *P*=0.0020). Responses to DRd *vs* Rd included CR or better in 52% *vs* 24% of these patients, and VGPR or better in 84% *vs* 51%. At 10^{-5} sensitivity threshold, MRD-negative rates for DRd *vs* Rd were 18% *vs* 0% (*P*=0.0027) among high-risk patients and 30% *vs* 10% (*P*<0.0001) for standard-risk patients. For CASTOR, the median follow-up was 13.0 months. Treating both high- and standard-risk patients with DVd *vs* Vd significantly prolonged median PFS (bottom panel Figure 1) and increased ORR (high risk: 82% *vs* 62%; *P*=0.039; standard risk: 85% *vs* 64%; *P*=0.0003). Responses to DVd *vs* Vd among high-risk patients included CR or better in 30% *vs* 9% of patients and VGPR or better in 64% *vs* 34%; among standard-risk patients, responses included CR or better in 25% *vs* 8% of patients and VGPR or better in 64% *vs* 27%. At 10^{-5} sensitivity threshold, MRD-negative rates for DVd *vs* Vd were 14% *vs* 0% (*P*=0.0018) among high-risk patients and 12% *vs* 2% (*P*=0.0011) for standard-risk patients.

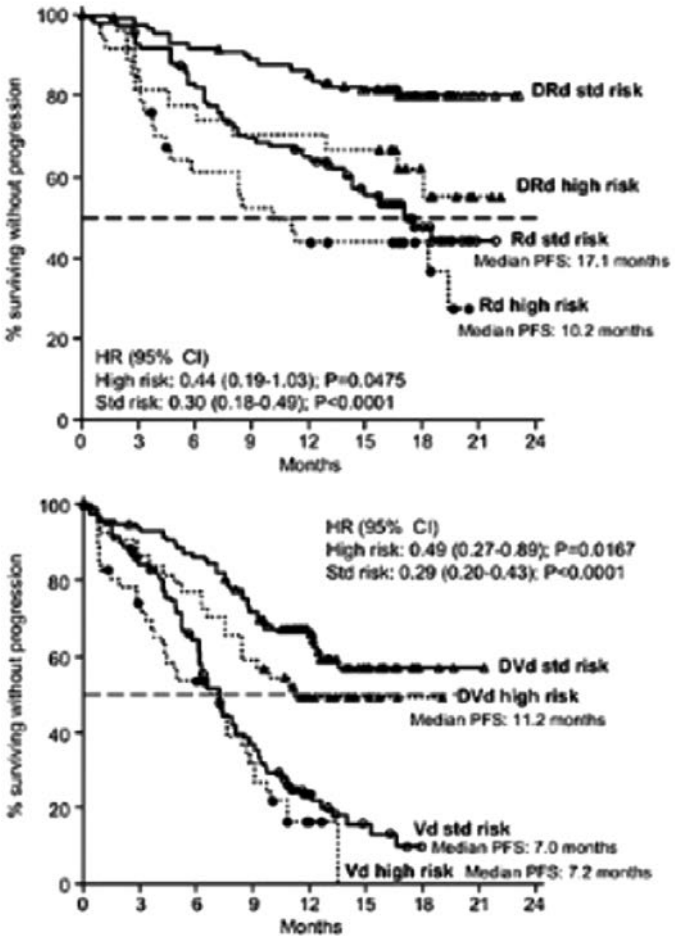

Figure 1.

Summary/Conclusions: Adding D to Rd or Vd improved treatment outcomes irrespective of cytogenetic risk status in patients with RRMM. Both DRd and DVd appear to benefit RRMM patients who have poor prognoses due to high-risk cytogenetic abnormalities. Updated data, including analyses based on individual cytogenetic abnormalities, will be presented at the meeting based on longer follow-up.

S102

MINIMAL RESIDUAL DISEASE BY MULTIPARAMETER FLOW CYTOMETRY IN TRANSPLANT ELIGIBLE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: RESULTS FROM THE EMN02/HO95 PHASE 3 TRIAL

Galli[5], R. Hajek[6], A. Palumbo[7], M. Cavo[5], P. Omedè[1], V. van der Velden[8], M. Boccadoro[1], P. Sonneveld[2]
[1]Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy, [2]Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [3]Department of Hematology, University Hospital Brno, Brno, Czech Republic, [4]Department of Hematology, Erasmus MC Cancer Institute, HOVON Data Center, Rotterdam, Netherlands, [5]Italian Multiple Myeloma Network, GIMEMA, Italy, [6]Department of Haematooncology, Faculty of Medicine, University of Ostrava and University Hospital of Ostrava, Ostrava, Czech Republic, [7]Myeloma Unit, Division of Hematology, University of Torino - Currently Takeda Pharmaceuticals Co., Torino, Zurich, Italy, Switzerland, [8]Department of Immunology, Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands

Background: Multiple myeloma (MM) is still an incurable disease and patients may relapse despite achievement of complete remission (CR). Available data show that MRD detection is a sensitive strategy to appropriately measure response in MM patients.

Aims: We evaluated MRD by MFC in patients with newly diagnosed MM enrolled in the EMN02/HO95 phase 3 trial.

Methods: Patients were ≤65 years of age and treatment consisted of Bortezomib-Cyclophosphamide-Dexamethasone (VCD) induction, mobilization and stem cell collection, intensification with Bortezomib-Melphalan-Prednisone (VMP) *vs* High-Dose-Melphalan (HDM) followed by stem cell transplant, consolidation with Bortezomib-Lenalidomide-Dexamethasone (VRD) *vs* no consolidation, and Lenalidomide maintenance. MRD was assessed in patients achieving at least a very good partial response (VGPR) before starting maintenance (after HDM, VMP or VRD) and during maintenance every 6-12 months; samples were centralized to 3 European labs. MFC was performed on bone marrow according to Euroflow-based methods (8 colors, 2 tubes) with a sensitivity of 10^{-5}. Quality checks were done to compare sensitivity and to show correlation between protocols (Hofste op Bruinink D, *ASH* 2016 abstract 2072).

Results: A total of 316 patients could be evaluated before maintenance: median age was 57 years (IQR: 52-62), 18% (57/316) had ISS III and 22% (70/316) had high risk cytogenetic abnormalities defined as presence of either one among del17, t(4;14) or t(14;16); 63% (199/316) had received HDM and 37% (117/316) VMP; thereafter 51% (160/316) had received VRD. After a median follow-up of 30 months from MRD enrolment, 76% (239/316) patients were MRD-negative: 64% (153/239) in the HDM *vs* 36% (86/239) in the VMP groups. The 3-year PFS was 50% in MRD-positive *vs* 77% in MRD-negative patients (HR 2.87, 95% CI: 1.75 - 4.72; p<0.001). Subgroup analyses were carried out to assess the risk factors for MRD-positivity according to baseline characteristics and therapies: high risk cytogenetic abnormalities were the most important risk factors (HR 9.87, 95% CI: 4.3 – 22.63; interaction-p=0.001). Finally, 48% of MRD positive patients at pre-maintenance who had a second MRD evaluation after at least 1 year of lenalidomide became MRD-negative.

Summary/Conclusions: MRD by MFC is a strong prognostic factor in MM patients receiving intensification with novel agents or transplant; lenalidomide maintenance further improved depth of response; high risk cytogenetic abnormalities are the most important prognostic factors in MRD-positive patients.

S103

PHASE I, OPEN-LABEL TRIAL OF ANTI-BCMA CHIMERIC ANTIGEN RECEPTOR T CELLS IN PATIENTS WITH RELAPSED/ REFRACTORY MULTIPLE MYELOMA

W. Zhang[1,*], W. Zhao[1], J. Liu[1], A. He[1], Y. Chen[1], X. Cao[1], N. Yang[1], B. Wang[1], P. Zhang[1], Y. Zhang[1], F. Wang[1], B. Lei[1], L. Gu[1], Y. Yang[1], J. Bai[1], R. Zhang[1], X. Wang[1], X. Ma[1], J. Wang[1], J. Wang[1], L. Wei[1], J. Zhang[1], X. Zang[1], Q. Zhuang[2], F.X. Fan[2]
[1]Hematology, Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, [2]Nanjing Legend Biotech, Nanjing, China

Background: Immunotherapy has emerged as a potentially curative treatment in hematological malignancies. Uniformly expressed in plasma cells, B-cell maturation antigen (BCMA) is an appropriate target antigens for CAR T-cell therapies in multiple myeloma.

Aims: This phase I, open-label trial was conducted to assess the efficacy and

safety profile of LCAR-B38M anti-BCMA CAR T cells in patients with relapsed/refractory multiple myeloma.
Methods: All patients underwent leukapheresis to obtain peripheral blood mononuclear cells and their T cells were engineered to express anti-BCMA CAR. Three doses of 300 mg/m^2 cyclophosphamide were administered on day -5, -4, and -3 (before the recruitment, patients took the same chemotherapy to identify they were refractory to cyclophosphamide monotherapy) and engineered-T cells were reinfused on day 0, 2, and 6. This trial was divided into the dose escalation stage and expansion cohort. Toxicity and responses were assessed according to the Common Terminology Criteria for Adverse Events (version 4.0) and International Myeloma Working Group (IMWG) Uniform Response Criteria for Multiple Myeloma, respectively.
Results: As of the February 20th, 2017 data cut-off, 22 patients had been enrolled, two of whom were diagnosed as plasma cell leukemia. The male: female ratio was 11:11 and median age was 53.5 years. Chromosomal abnormalities were detectable by FISH in eight patients, two of whom involved in the deficiency of p53. Eleven patients were triple refractory (chemotherapy, proteasome inhibitors, and immunomodulatory drugs), 11 resisted to double prior treatments (chemotherapy and proteasome inhibitors/ immunomodulatory drugs), and four relapsed after autologous hematopoietic stem cell transplant. The median number of infused CAR T cells was 4.0×10E6 (range, 1.5×10E6-7.0×10E6) per kg. The median follow-up was 131.5 (range, 29-327) days. 100% of patients achieved an objective response. The first six patients achieved complete responses with flow MRD-negative; 14 patients achieved very good partial responses; one patient, with renal failure, achieved partial response; all these 22 patients had kept their best response at the end of follow-up. The pictures we enclosed were the subcutaneous nodules in one patient with extramedullary plasmacytoma. We found that the nodules were obviously decreased after the infusion and disappeared finally. Another one achieved transient partial response, which last for 12 days. He then took the secondary infusion but failed since the post-operation large-dose administration of corticosteroid for spinal meningioma. He terminally died of the progression of myeloma. The most common toxicity attributable to CAR T cells was cytokine release syndrome (CRS). Toxicities were minimal except for two grade 3 CRS and one grade 4 CRS. All CRSs were controllable with nonsteroidal anti-inflammatory drugs (NSAIDs) or tocilizumab and no dose-limiting toxicities or treatment-related deaths were observed (Figure 1).

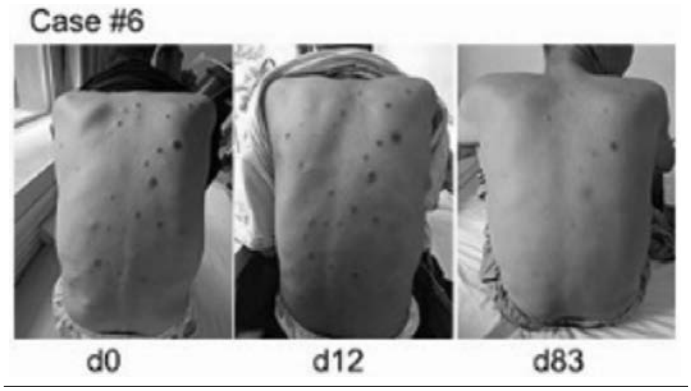

Figure 1.

Summary/Conclusions: Our findings demonstrated the safety and antimyeloma activity of LCAR-B38M anti-BCMA CAR T cells.

S104

PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS TREATED WITH NEOD001 ACHIEVE RAPID ORGAN RESPONSES THAT ARE INDEPENDENT OF PREVIOUS PLASMA CELL–DIRECTED THERAPIES

M.A. Gertz[1,*], R.L. Comenzo[2], H. Landau[3], V. Sanchorawala[4], B.M. Weiss[5], J.A. Zonder[6], J. Walling[7], G.G. Kinney[8], M. Koller[8], D.B. Schenk[8], S.D. Guthrie[8], E. Liu[8], M. Liedtke[9]
[1]Mayo Clinic, Rochester, [2]Tufts Medical Center, Boston, [3]Memorial Sloan Kettering Cancer Center, New York, [4]Boston University School of Medicine and Boston Medical Center, Boston, [5]University of Pennsylvania, Philadelphia, [6]Karmanos Cancer Institute, Detroit, [7]JW Consulting, Hillsborough, [8]Prothena Biosciences Inc, South San Francisco, [9]Stanford University School of Medicine, Stanford, United States

Background: Light chain (AL) amyloidosis is a rare and often fatal disease caused by the accumulation of misfolded light chain (LC) aggregates that can lead to progressive failure of critical organs, causing significant morbidity and mortality. Patients' survival depends upon rapid suppression of the misfolded LC and stabilization or recovery of organ function. Current therapies limit LC production; however, ~75% of patients have persistent organ dysfunction. NEOD001 is a novel investigational monoclonal antibody that targets misfolded LC and may neutralize circulating LC aggregates and clear insoluble deposits.
Aims: To assess the association between responses and time, depth, number or type of previous plasma cell–directed (PCD) treatments and organ response.
Methods: Inclusion criteria for this trial were: completed ≥1 PCD treatment before enrollment, attained partial hematologic response (HR) or better to any previous therapy, and have persistent organ dysfunction. NEOD001 was administered intravenously every 28 days. During the dose-escalation phase, 27 patients received NEOD001 at 0.5, 1, 2, 4, 8, 16, or 24 mg/kg in a 3+3 study design. In the expansion phase, 42 additional patients with renal, cardiac, or nerve involvement were enrolled and treated (24 mg/kg). We assessed cardiac and renal best responses based on consensus criteria. Peripheral nervous system (PN) responses were assessed at month 10 (after 9 infusions) using the Neuropathy Impairment Score–Lower Limbs (NIS-LL). We explored the potential impact on organ response of the number and type of organs affected and the number of, type of, and time since previous therapies at baseline.
Results: In the overall population (N=69), the median age was 61 years (61% male). Median (range) time since diagnosis was 2.9 (0.4-16.0) years, and 45% of patients underwent ≥3 previous PCD regimens. Median time to first best response was 1.8 (cardiac), 3.7 (renal), and 1.0 (PN) months. Best response rate indicating organ response was observed in 53% of cardiac-evaluable patients (n=19/36) and 64% of renal-evaluable patients (n=23/36). PN responses were observed in 82% (n=9/11) of PN-evaluable patients. Time from patients' best HR to previous PCD treatment was not related to the attainment of NEOD001 organ response (responder/stable: 35.6/36/6 months [cardiac] and 30.6/32.5 months [renal]; P>0.05). Depth of patients' best HR also was not related to the attainment of NEOD001 organ response (percentage of patients with organ response in CR/VGPR/PR after PCD: 47.1/66.7/42.9% [cardiac] and 68.8/63.6/62.5% [renal]; P>0.05). Similarly, time or depth of patients' last HR did not impact the NEOD001 organ response rate (P>0.05). Patients with NEOD001 organ responses were no more likely to have had their last PCD therapy <6 than ≥6 months from their first NEOD001 dose. Patients' previous PCD treatment type was not related to the attainment of NEOD001 organ response (percentage of patients undergoing: stem cell transplantation, 55.6/61.1% [cardiac/renal]; bortezomib-based therapy, 52.0/68.8%; or other chemotherapy, 50.0/57.1%; P>0.05). Exploratory analyses showed no association between the time to response or percentage of responders and the number of previous PCD treatments.
Summary/Conclusions: NEOD001 specifically targets disease-causing, misfolded LC aggregates in AL amyloidosis. Organ responses in patients treated with monthly NEOD001 infusions were achieved rapidly and independently of time since previous chemotherapy, depth of hematologic response, or predominant type of PCD treatment.

Aggressive Non-Hodgkin lymphoma - 1st line

Background: Mantle cell lymphoma (MCL) is currently an incurable disease. In spite of high complete response rates (CR) after initial immunochemotherapy induction followed by autologous stem cell transplantation (ASCT), MCL patients experience iterative relapses.
Aims: We investigated whether or not rituximab maintenance (RM; 375mg/m^2 every 2 months for 3 years) after ASCT prolongs response duration.
Methods: This phase III trial included 299 patients (<66y) at diagnosis, of whom 240 were randomly assigned to RM or observation after ASCT. The primary end point was event-free survival (EFS) (progression, relapse, death, severe infection during RM) after ASCT.
Results: After 4 courses of immunochemotherapy induction (R-DHAP; Rituximab, dexamethasone, cytarabine, platinium derivative), overall response and CR rates were 89.3% and 77.3%, respectively. ASCT was performed in 257 patients. Median follow-up from randomization after ASCT was 50.2 (46.4-54.2) months. Starting from randomization, 4-year EFS was 78.9% (95%CI; 69.5 to 85.6) for RM (n=120) *versus* 61.4% (95%CI; 51.3 to 69.9) for observation (n=120) (p=0.0012), 4-year progression-free survival (PFS) was 82.2% (95%CI; 73.2 to 88.4) for RM *versus* 64.6% (95%CI; 54.6 to 73) for observation (p=0.0005) and OS was 88.7% (95%CI; 80.7 to 93.5) for RM *versus* 81.4% (95%CI; 72.3 to 87.7) for observation (p=0.0413). The death rate was lower for patients in the RM arm were less likely to die (hazard ratio (HR)=0.5; 95%CI, 0.255 to 0.986) than for patients in the observation arm.
Summary/Conclusions: The LyMa trial demonstrates for the first time that RM after ASCT prolongs EFS, PFS and OS. Thus, 4 courses of R-DHAP plus ASCT (without TBI) followed by RM maintenance (one infusion every 2 month for 3 years) is a new standard of care for young MCL patients.

S106

POLA-R-CHP: POLATUZUMAB VEDOTIN COMBINED WITH RITUXIMAB, CYCLOPHOSPHAMIDE, DOXORUBICIN, PREDNISONE FOR PATIENTS WITH PREVIOUSLY UNTREATED DIFFUSE LARGE B-CELL LYMPHOMA

H. Tilly[1,*], J. Sharman[23], N. Bartlett[4], F. Morschhauser[5], C. Haioun[6], J. Munoz[7], A. Chen[8], T. Lamy[9], L. Wang[10], E. Penuel[10], J. Hirata[10], C. Lee[10], G. Salles[11]
[1]Centre Henri Becquerel, University of Rouen, Rouen, France, [2]Willamette Valley Cancer Institute, Springfield, [3]US Oncology Research, The Woodlands, [4]Siteman Cancer Center, Washington University School of Medicine, St Louis, United States, [5]University Hospital of Lille, Lille, [6]Henri Mondor University Hospital, Creteil, France, [7]Banner MD Anderson Cancer Center, Gilbert, [8]Oregon Health and Science University, Portland, United States, [9]Hematology Department, INSERM U917 / University Hospital of Rennes, Rennes, France, [10]Genentech, Inc., South San Francisco, United States, [11]South Lyon Hospital Complex, Lyon, France

Background: Polatuzumab vedotin (pola) is an antibody drug conjugate containing the anti-mitotic MMAE targeting CD79b, an antigen expressed ubiquitously in DLBCL. Pola as monotherapy and in combination with anti-CD20 antibodies demonstrated encouraging efficacy in r/r DLBCL.[1,2] The initial dose-escalation portion of this multicenter, open-label Ph Ib/II study of pola in combination with rituximab, cyclophosphamide, doxorubicin, and prednisone (pola-R-CHP) showed an acceptable safety profile and established a recommended Ph II dose of pola at 1.8 mg/kg.[3] We report updated safety and efficacy results for the Ph II dose in 45 previously untreated DLBCL patients (pts) (ClinicalTrials.gov NCT01992653).
Aims: To evaluate the safety and efficacy of pola-R-CHP as first-line treatment in patients with DLBCL.
Methods: Five pts of the dose escalation phase and the 40 pts of the expansion phase were included in this analysis. All pts provided informed consent to participate in the study. All had newly diagnosed DLBCL and were treated with pola at 1.8 mg/kg and R-CHP at standard doses every 21 days for 6 or 8 cycles. Investigator assessments for anti-tumor activity were performed according to IWG 2007 following 4 cycles and at the end of study treatment (EOT).
Results: All 45 pts received at least one dose of study drug. The median age was 69 years; 93% were >60 years, 33% ECOG >1, 82% Stage III/IV, and 78% IPI 3-5. Of the 29 pts with cell of origin (COO) status by digital gene expression, 11 (38%) were ABC, 14 (48%) were GCB, while 4 (14%) were unclassified. Forty patients completed 6 or 8 cycles (23 and 17 pts respectively). All pts experienced at least one AE. Grade (Gr) 3/4 AEs occurred in 58%, and one pt experienced a Gr 5 atrial fibrillation. Gr 3/4 neutropenia and febrile neutropenia (FN) occurred in 27% and 11%. Serious adverse events (SAEs) were reported in 17 pts (38%) including 3 FN, and 2 each of neutropenia, pneumonia, pulmonary embolism and influenza A. Peripheral neuropathy (PN) occurred in 18 (40%) patients. Among these pts with PN, 12 were Gr 1, 4 were Gr 2, and 2 were Gr 3. All Gr 2/3 PN attributed to pola occurred at C5 or later. Four pts discontinued pola early for the following reasons: Gr 5 atrial fibrillation (after C2, not attributed to pola by investigator), E. coli UTI (C5), worsening essential tremor (C3), PN (C7). During treatment, 6 pts had dose reductions in pola and 1 pt had cyclophosphamide and doxorubicin dose reductions. ORR by PET at EOT was 91%; 78% had a CR and 13% PR. 3 pts progressed and 1 was unevaluable. In the COO determined population, CR was 91% in ABC and 86% in GCB pts. At the data cutoff of November 4, 2016 with a median study duration of 9.5 months, (range 1.3-28 months), only 1 pt had a disease progression in follow up.
Summary/Conclusions: Pola at 1.8 mg/kg in combination with R-CHP in 1L DLBCL has an acceptable safety profile and produced promising response rates at the end of treatment. The majority of the patients in this trial represented a poor prognosis group by age and IPI. In this context, treatment response to this regimen may warrant further exploration.

Hoffmann-La Roche Ltd, Basel, Switzerland, [12]Department of Internal Medicine I, University Hospital of Saarland, Homberg, Germany

Background: Intravenous (IV) rituximab plus chemotherapy is standard treatment for diffuse large B-cell lymphoma (DLBCL). A subcutaneous (SC) formulation of rituximab may simplify treatment and reduce burden.
Aims: MabEase (NCT01649856) studied efficacy, safety and patient (pt) satisfaction with rituximab SC or IV plus CHOP as first-line DLBCL treatment.
Methods: Pts were randomized 2:1 to rituximab SC (IV 375mg/m^2 cycle 1; SC 1400mg cycles 2–8) or IV (375mg/m^2 cycles 1–8) plus CHOP every 14 or 21 days. The primary endpoint was investigator-assessed complete response (CR)/unconfirmed CR (CRu) at the end of induction (EOI). Secondary endpoints included safety, survival, treatment satisfaction (Cancer Treatment Satisfaction Questionnaire [CTSQ], Rituximab Administration Satisfaction Questionnaire [RASQ]) and time savings. Follow-up continued until at least 24 months after EOI in the last patient recruited.
Results: Of 576 pts (381 SC; 195 IV), 572 (378 SC; 194 IV) received treatment. EOI CR/CRu rates were 50.6% (95% CI 45.3–55.9) and 42.4 (95% CI 35.1–49.7) in the SC and IV groups, respectively (Table 1). After 35 months' median follow-up, median progression-free survival (PFS), event-free survival (EFS) and overall survival (OS) were not reached in either arm and no statistically significant differences were observed between treatment arms. PFS, EFS and OS rates were also similar at 24 months' follow-up (non-significant differences; Table 1). Grade ³3 adverse events (58.3% SC; 54.3% IV) and administration-related reactions (21% in both groups) were similar between arms. Of SC recipients, 5.7% had injection site reactions *vs* none in the IV group (p<0.001). Febrile neutropenia occurred more often in the SC arm (12.5% *vs* 6.9% in IV, p=0.06). RASQ scores for 'impact on activities of daily living', 'convenience' and 'satisfaction' were improved with SC *vs* IV; CTSQ scores were similar between arms (Figure 1).

When pts in the SC group were asked, if given the option, which treatment they would prefer, 90.8% stated a preference for SC over IV. Median administration time (6 minutes SC *vs* 2.6–3.0 hours IV) and chair/bed and overall hospital times were shorter with SC than with IV treatment.

Table 1. Efficacy endpoints in the intent-to-treat population.

Efficacy endpoint	Rituximab SC plus CHOP		Rituximab IV plus CHOP	
	N	% (95% CI)	N	% (95% CI)
End of induction treatment				
CR/CRu	342	50.6 (45.3–55.9)	177	42.4 (35.1–49.7)
PR	342	31.6 (26.7–36.8)	177	35.6 (28.6–43.1)
PD	342	3.8 (2.0–6.4)	177	6.2 (3.1–10.8)
ORR	342	82.2 (77.7–86.1)	177	78.0 (71.1–83.8)
24 months' follow-up				
PFS*	342	67.5 (62.6–72.5)	177	72.3 (65.7–78.9)
EFS†	342	61.7 (56.5–66.8)	177	66.7 (59.7–73.6)
OS	342	87.4 (83.2–90.5)	177	88.0 (82.0–92.1)

*p=0.264.
†p=0.265.

Figure. Patient satisfaction at cycle 3 and cycle 7 of treatment

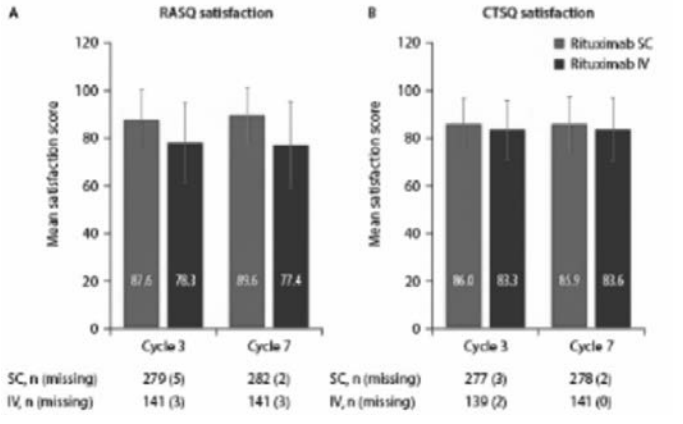

Figure 1. Patient satisfaction at cycle 3 and cycle 7 of treatment.

Summary/Conclusions: Rituximab SC had similar efficacy and safety to the IV form, with improvements in patient satisfaction ratings, and administration/hospital time savings. Our findings support the use of rituximab SC in this setting.

S108

ANALYSIS AND CHARACTERIZATION OF HEMATOLOGIC CANCERS USING A COMPREHENSIVE NGS PANEL COMPRISED OF DNA AND RNA BAITS TARGETING 704 GENES

A.R. Carson[1], B.A. Patay[1], V. McClain[1], Z. Xie[1], T. Stenzel[1,2,3,*], J.E. Miller[1,2,3]
[1]Invivoscribe, [2]LabPMM LLC, San Diego, United States, [3]LabPMM GmbH, Martinsried, Germany

Background: As next-generation sequencing (NGS) methodologies improve, so does the ability to characterize hematopoietic and lymphoid neoplasm genomes. This promises to revolutionize oncology, allowing more accurate and precise classification of patients and potentially leading to novel targeted and combination therapies with improved outcomes.
Aims: We constructed a custom targeted sequencing panel, MyHEME™, to comprehensively identify and characterize DNA and RNA changes in a broad range of hematologic malignancies, including Non-Hodgkin lymphoma (NHL).
Methods: The MyHEME targeted sequencing panel is comprised of two independent bait sets that target a combined 704 genes known or predicted to contribute to hematologic cancers (DNA baits for 571 genes and RNA baits for 361 genes; 228 genes are found in common between the two bait sets). Libraries were constructed using 1µg of DNA or 0.1µg of RNA and sequenced on an Illumina platform. Sequenced reads are analyzed using proprietary MyInformatics™ software to identify single nucleotide variants (SNVs), indels and structural variants (SVs). Both the MyHEME panel and MyInformatics software were created under ISO13485 design control. To characterize the performance metrics of the MyHEME panel, we used the NIST human reference sample NA12878 along with combinations of hematologic cancer derived cell lines with known pathogenic variants at various allelic frequencies.
Results: Analytical validation of the MyHEME panel established an average read depth of 1,175x (with a median read depth of 1,088x) for the DNA targets and an average transcripts per million (TPM) of 2,256 (with a median TPM of 743) for the RNA targets. For the DNA targets, we establish sensitivity >95% (99.8% for SNVs at a 2.5% limit of detection (LOD); 100% for coding indels at a 5.0% LOD) and specificity >95% (95.5% for SNVs at a 2.5% LOD; 97.7% for coding indels at a 5.0% LOD). We also show the ability to cross-confirm results between the 228 genes common to both the DNA and RNA targets. Importantly, novel gene fusions, which are generally difficult to detect and validate, were cross-confirmed when observed in both the DNA and RNA targets. For example, we identified a novel t(9;22) translocation causing a *NUP214-XKR3* gene fusion using both the DNA and RNA targets. Additionally, while RNA data provides the fused exons of the transcripts, DNA data gives the precise genomic breakpoint coordinat
Summary/Conclusions: MyHEME is an extensive panel for sensitively and specifically identifying SNV, indel and SV mutations in 704 target genes. This panel can comprehensively characterize mutations in multiple diverse hematologic cancer samples, including Non-Hodgkin Lymphoma, AML, ALL, and Multiple Myeloma. By utilizing a high depth of coverage, MyHEME can accurately detect clones present down to 5% of a patient's sample. In addition, by targeting both DNA and RNA, MyHEME contains a built in validation method to cross-confirm novel variants of interest.

S109

TP53 MUTATIONS, BUT NOT DELETION OF TP53 AND CDKN2A, HAVE INDEPENDENT PROGNOSTIC VALUE IN MANTLE CELL LYMPHOMA TREATED BY THE NORDIC (MCL2 AND MCL3) REGIMEN

C.W. Eskelund[1,*], C. Dahl[2], J. W. Hansen[1], M. Westman[1], C. Montano[1], C. Freiburghaus[3], S. Ek[3], A. Pedersen[1], L.B. Pedersen[1], C. Niemann[1], R. Räty[4], P. Brown[1], A. Kolstad[5], C.H. Geisler[1], M.K. Andersen[1], P. Guldberg[2], M. Jerkeman[3], K. Grønbæk[1]
[1]University Hospital of Copenhagen, [2]Danish Cancer Society, Copenhagen, Denmark, [3]University Hospital of Lund, Lund, Sweden, [4]University Hospital of Helsinki, Helsinki, Finland, [5]University Hospital of Oslo, Oslo, Norway

Background: During the past decades, the outcome of MCL treatment has improved substantially in younger patients. However, the course of disease remains heterogeneous, and there is a need for better stratification of patients with poor responses from those with durable responses. The Nordic trials, MCL2 and MCL3, represent standard-of-care regimens for younger MCL patients.
Aims: Preliminary analyses of diagnostic samples from MCL2 and MCL3, show that TP53 mutations are associated with significantly poorer outcome. Recently, deletions of TP53 and CDKN2A was shown to confer negative impact in a cohort similar to the Nordic.(Delfau-Larue *et al.,* 2015) Thus, in this study we aim to describe the prevalence and impact of deletions of TP53 and CDKN2A in the light of TP53 mutations.
Methods: Fresh frozen DNA from diagnostic bone marrow samples from MCL2 and MCL3 were analyzed. In both trials, patients received intensified first-line induction therapy with alternating courses of R-CHOP and R-hd-Cytarabine and consolidation with high-dose therapy and ASCT. (Geisler *et al.,* 2008; Kolstad *et al.,* 2014). Targeted NGS of *ATM, CCND1, TP53, KMT2D, NOTCH1, NOTCH2, WHSC1 and BIRC3* was performed by Ion Torrent Technology. Cut-off for calling a mutation was set to a variant allele frequency >3%. Median coverage was >2700X. Copy Number Variations (CNVs) of TP53 and CDKN2A were measured by droplet digital PCR by commercially available assays, and RPP30 used as a standard control.
Results: We investigated the presence of CDKN2A and TP53 deletions in diagnostic samples from 175 and 157 patients, respectively. Patients were untreated and <66 years (median 58, range 37-65). Fifty-three percent were either MIPI intermediate- or high-risk, 17% had blastoid morphology and 42% had Ki67≥30%, and 83% had bone marrow involvement at diagnosis. After a median follow-up of 9.2 years, median overall (OS), progression-free survival (PFS) and cumulated incidence of relapse (CIR) of all patients were 12.4 and 8.2 and 10.2 years, respectively. In our mutational analyses (n=147), only TP53 had prognostic impact in multivariate analyses (MVAs). Outcome of the 15 patients (10%) with TP53-mutations was poor with a median OS, PFS and CIR of 1.8, 1.0 and 1.2 years (p<0.0001 for all three outcomes), respectively. Preliminary data shows deletions of TP53 in 28 patients (18%) and deletion of CDKN2A in 38 (22%). Eight patients carried both deletions. Del-CDKN2A was significantly associated with mutations of TP53, MIPI high risk, blastoid morphology and Ki67>30%. Del-TP53 was associated with Ki67>30%, but no other high risk markers. Altogether, 31 (25%) of 122 patients harbored a deletion and/or mutation in TP53 and 4 (3%) carried both aberrations. In univariate analyses, del-TP53 was significantly associated with poor OS (p=0.01), but not PFS and CIR, whereas del-CDKN2A was significant for CIR (p=0.02), but not OS and PFS. Patients with both deletions did significantly worse for all three endpoints. In MVA, (including all factors with significance in univariate analyses: MIPI, blastoid morphology, Ki67-index>30%, NOTCH1 mutations, TP53 mutations, del-TP53 and del-CDKN2A) only mutations of TP53 remained a significant predictor of outcome.
Summary/Conclusions: Here we evaluate the impact of TP53- and CDKN2A-deletions in the context of TP53 mutations of younger, optimally treated MCL patients. In line with previous reports, both deletions were associated with poorer outcome; however, in multivariate analyses only TP53 mutations was an independent prognostic factor, substantiating its role as a biomarker for response to the standard-of-care immune-chemotherapy.

MRD directed treatment in AML

DEEP MOLECULAR RESPONSE TO GILTERITINIB IMPROVES SURVIVAL IN FLT3 MUTATION-POSITIVE RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA

A. Jessica[1,*], A. Perl[2], J. Cortes[3], C. Smith[4], M. Litzow[5], J. Hill[6], R. Larson[7], C. Liu[6], E. Ritchie[8], S. Strickland[9], E. Wang[10], A. Neubauer[11], G. Martinelli[12], E. Bahceci[6], M. Levis[13]
[1]Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, [2]University of Pennsylvania, Philadelphia, [3]University of Texas MD Anderson Cancer Center, Houston, [4]University of California San Francisco, San Francisco, [5]Mayo Clinic, Rochester, [6]Astellas Pharma US, Inc., Northbrook, [7]University of Chicago, Chicago, [8]Weill Cornell Medical College of Cornell University, New York, [9]Vanderbilt-Ingram Cancer Center, Nashville, [10]Roswell Park Cancer Institute, Buffalo, United States, [11]University Clinic Giessen Marburg, Marburg, Germany, [12]University of Bologna, Bologna, Italy, [13]The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, United States

Background: Mutations in Fms-like tyrosine kinase 3 (FLT3) are common in patients with acute myeloid leukemia (AML) and are associated with an aggressive disease course and a poor prognosis. Notably, FLT3 internal tandem duplications (ITD) predict early relapse and short overall survival (OS) after chemotherapy. Gilteritinib, a highly selective FLT3/AXL inhibitor, has displayed antileukemic activity in FLT3 mutation-positive (FLT3^{mut+}) relapsed/refractory (R/R) AML in the CHRYSALIS Phase 1/2 study (NCT02014558), specifically at doses ≥80 mg/d.
Aims: To assess molecular response to gilteritinib in a CHRYSALIS subpopulation.
Methods: This exploratory analysis evaluated molecular response in patients aged ≥18 years with FLT3^{mut+}R/R AML who had been treated with 120 or 200 mg/d gilteritinib. These doses were identified due to their ability to induce high clinical response rates, and consistent, potent FLT3 inhibition in correlative assays. Molecular response was assessed in patients who had bone marrow aspirates obtained at baseline and at ≥1 additional time point. *FLT3-ITD* and total *FLT3* were quantified by next-generation sequencing to assess molecular response. A Cox regression model of OS by Kaplan-Meier estimation established a *FLT3-ITD*:total *FLT3* ratio (ITD signal ratio) of 10^{-2} as the threshold for improved survival.
Results: Of the 147 FLT3-ITD^{mut+}patients who had received gilteritinib 120 or 200 mg/d, 80 patients had bone marrow aspirates at baseline and at ≥1 additional time point, and were included in this analysis. The composite response rate (defined as CR plus CRi plus CRp) for these 80 patients was 55%. During response, 20 patients (25%) had an ITD signal ratio of $\leq 10^{-2}$. Of these 20 patients, 18 had an ITD signal ratio of $\leq 10^{-3}$ (major molecular response [MMR]) and 13 had an ITD signal ratio of $\leq 10^{-4}$ (minimal residual disease [MRD] negative). The median time to achieve minimum ITD signal ratio was 54 days. Elimination of morphologic leukemia was observed in 80% of patients with ITD signal ratios $<10^{-2}$. Patients who had an ITD signal ratio $\leq 10^{-2}$, MMR, or were MRD negative had significantly longer median OS than those who did not (Table 1 and Figure 1).

Table 1. Overall survival in subjects who achieved a molecular response compared with those who did not by depth of response.

Molecular Response	Achieved a Molecular Response		Did not Achieve a Molecular Response		*P*-value
	n	Median OS, Days (95% CI)	n	Median OS, Days (95% CI)	
ITD signal ratio $\leq 10^{-2}$	20	417 (246–NA)	60	199 (142–234)	<.001
MMR	18	417 (228–NA)	62	213 (143–264)	.003
MRD negative	13	417 (228–NA)	67	213 (144–264)	.002

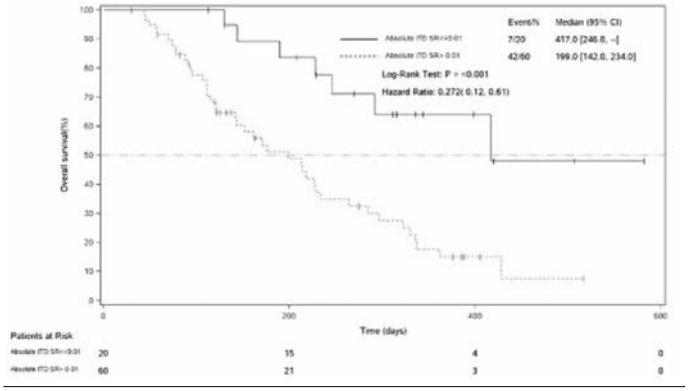

Figure 1.

Summary/Conclusions: Molecular responses to gilteritinib in FLT3-ITD^{mut+}R/R AML correlated with clinical response and improved OS. This is the first demonstration of a robust molecular response to a FLT3 inhibitor in AML. These data suggest that the ITD signal ratio may predict a durable clinical benefit of gilteritinib therapy and validate FLT3 as a critical therapeutic target in AML.

Background: A comprehensive AML risk assessment, based on the integration of cytogenetic/genetic data and minimal residual disease (MRD) status, can help optimize patients' (pts) therapeutic post-remission allocation.
Aims: To evaluate the feasibility and results of a phase II trial of intensive chemotherapy in which risk-assignment and post-remission therapy of young patients with AML was based on pre-treatment cytogenetic/genetic data and post-consolidation levels of MRD.
Methods: Between January 2012 and May 2015, 515 pts with de novo AML, 18 to 60 years old, seen at 55 GIMEMA institutions were enrolled in the trial. Induction consisted of i.v. daunorubicin 50 mg/m^2 daily on days 1,3 and 5; i.v. etoposide 50 mg/m^2 daily on days 1 to 5; i.v. cytarabine 100 mg/m^2 as a daily continuous infusion, days 1 to 10. All pts in CR/CRi after 1-2 induction cycles, received 1 consolidation course consisting of i.v. daunorubicin 50 mg/m^2 daily on days 4,5 and 6 and i.v. cytarabine 500 mg/m^2 every 12 hours on days 1 to 6. In pts belonging to ELN low or intermediate-risk category, peripheral blood stem cell collection was attempted by initiating, on day 20 from the start of consolidation therapy, G-CSF until completion of stem cell collection. Post-consolidation therapy was based on risk-allocation. Low-risk pts (NPM1 positive FLT3-ITD negative or CBF positive without c-Kit mutations) were to receive AuSCT; high-risk pts (adverse karyotype or FLT3-ITD positive) were to receive ASCT; intermediate-risk pts (intermediate karyotype or FLT3-TKD positive or c-kit mutated CBF positive) were to receive AuSCT or ASCT depending on the levels of MRD, measured by flow cytometry after consolidation therapy. Allocation to ASCT required the procedure to be performed whatever the source of stem cells (identical sibling, unrelated, cord blood, haploidentical).
Results: 500/515 pts started treatment and were available for the analysis. Median age was 49 (18-61) years and 52% were males. Of 429 evaluable pts, ELN cytogenetic distribution was: low-risk 11%, intermediate-risk 73% and poor-risk 16%. RUNX1/RUNX1T1 was detected in 5% of 499 evaluable cases, CBFbeta/MYH11 in 7% of 496, FLT3-ITD in 25% of 497 and NPM1 in 37% of 499. In 494 evaluable pts, complete remission rate (CR) was 73% (361), 18% had refractory AML and 9% died early during induction. Three hundred-41 pts completed the consolidation phase and were risk allocated: 114 (33%) to the low-risk category (=AuSCT), 122 (36%) to the high-risk (=ASCT) and 78 (23%) to the intermediate category (=AuSCT or ASCT). In 27 pts (8%) belonging to the intermediate-risk category, a leukemia associated phenotype was not found and they were to receive AuSCT. Overall, 109 (33%) and 123 (36%) of 341 pts received AuSCT and ASCT, respectively. Median follow-up was 27.9 months. At 24 months, overall (OS) and disease free survival (DFS) of the whole series was 55.9% and 54.9%, respectively; cumulative incidence of relapse was 32.9%. At the same time point of 24 months, OS and DFS in the low-risk category was 74.8% and 63.8%, respectively; in the high-risk category 42.5% and 44.8%, respectively; in the intermediate-risk category MRD negative 78.6% and 61.4%, respectively; in the intermediate-risk category MRD positive 69.8% and 66.6%, respectively (Figure 1).
Summary/Conclusions: A program of risk-adapted, MRD-driven therapy is feasible in a multicenter, cooperative setting. In the intermediate-risk category,

ASCT can be avoided if MRD is not detectable; if MRD is positive, ASCT can prolong OS and DFS to equalize those of the low-risk category. ASCT was delivered to 2/3 of pts in the high-risk category, using all the available sources of stem cells.

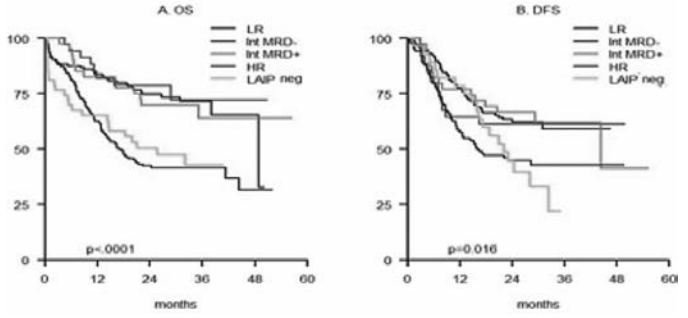

Figure 1.

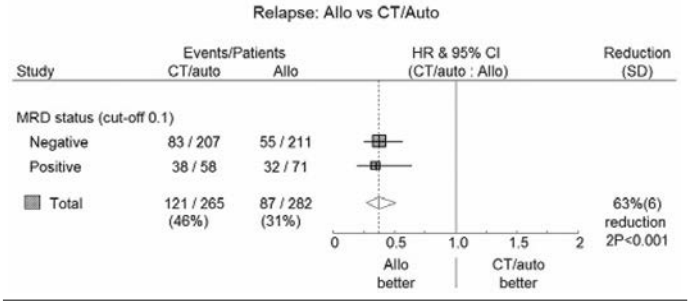

Figure 1.

Summary/Conclusions: The graft-*versus*-leukemia effect of alloHSCT is equally present in MRD positive and MRD negative patients, which advocates a personalized application of alloHSCT taking the risk of relapse determined by AML risk group and MRD status as well as the counterbalancing risk of NRM into account.

S112

GRAFT VERSUS LEUKEMIA EFFECT OF ALLOGENEIC STEM CELL TRANSPLANTATION AND MINIMAL RESIDUAL DISEASE IN PATIENTS WITH AML IN FIRST COMPLETE REMISSION

[1]Erasmus Medical Center Cancer Institute, Rotterdam, [2]VU University Medical Center, Amsterdam, Netherlands, [3]University Hospital Basel, Basel, Switzerland, [4]Mont-Godinne, Yvoir, Belgium, [5]University Hospital Zürich, Zürich, Switzerland, [6]Cliniques universitaires Saint-Luc, UCL, Brussels, Belgium, [7]Academic Medical Center, University of Amsterdam, Amsterdam, [8]Medisch Spectrum Twente, Enschede, [9]Isala Hospital, Zwolle, Netherlands, [10]Inselspital, Bern University Hospital, Bern, Switzerland

Background: The detection of minimal residual disease (MRD) in patients with acute myeloid leukemia (AML) may improve future risk-adapted strategies of AML treatment. The presence of MRD after induction treatment has firmly been shown to predict for relapse and overall outcome, irrespective of type of post-remission treatment (PRT). Currently it is unknown whether and how the presence or absence of MRD should guide the application of allogeneic hematopoietic stem cell transplantation (alloHSCT) as PRT.

Aims: We addressed whether and to what extent alloHSCT quantitatively reduces relapse as compared to conventional post-remission treatment (PRT) in upfront treated patients with MRD positive or MRD negative AML in first hematological complete remission (CR1).

Methods: A total of 1,511 patients were treated in subsequent HOVON-SAKK AML trials of whom 547 patients obtained a CR1, received PRT and had available flow cytometric MRD prior to PRT. MRD positivity was defined by more than 0.1% cells with a leukemia associated phenotype within the white blood cell compartment. MRD status was not known by clinicians during AML treatment. PRT consisted of alloHSCT (n=282), or conventional PRT by a third cycle of chemotherapy (n=160) or autologous HSCT (n=105). Endpoints of the study included overall survival (OS), relapse-free survival (RFS), and cumulative incidences of relapse and non-relapse mortality (NRM) at 4 years. A time-dependent analysis was performed by applying multivariable Cox regression with time-dependent covariate alloHSCT with the cumulative incidence of relapse as primary endpoint.

Results: MRD was positive in 129 (24%) patients after induction chemotherapy before proceeding to PRT. The latest European LeukemiaNET risk classification was similarly distributed among MRD negative and MRD positive patients. No differences were present in transplant characteristics in MRD positive and MRD negative patients. OS and RFS was significantly better in patients without MRD prior to PRT as compared to MRD positive patients (65±2% compared to 50±5% at 4 years, p=0.002, and 58±3% compared to 38±4%, p<0.001, respectively). Improved outcome was mainly caused by a lower cumulative incidence of relapse in MRD negative patients as compared to MRD positive patients (32±2% compared to 54±4% at 4 years, p<0.001, respectively), while NRM was not significantly different and estimated 10±1%. NRM split by EBMT risk score showed less NRM in patients with a low EBMT-risk score as compared to patients with a high EBMT risk score (≤2 compared to >2, 10±2% compared to 22±4%, p=0.005, respectively). Multivariable analysis with adjustment for covariates showed that the incidence of relapse was significantly reduced following alloHSCT as compared to chemotherapy or autologous HSCT (HR 0.36, p<0.001), which was similarly exerted in MRD negative and positive patients (HR 0.38, p<0.001 and HR 0.35, p<0.001). RFS was also improved following alloHSCT as compared to chemotherapy or autoHSCT (HR 0.53, p<0.001), while no significant differences were found for OS (Figure 1).

S113

LEUKEMIC STEM CELL FREQUENCY COMBINED WITH MRD IS AN IMPORTANT BIOMARKER TO PREDICT RELAPSE IN ACUTE MYELOID LEUKEMIA. RESULTS FROM A PROSPECTIVE H102 STUDY

[1]Hematology, VU University Medical Center, Amsterdam, [2]Clinical Trial Center-HOVON data center, Erasmus University Medical Center, Rotterdam, Netherlands, [3]Hematology, University Hospitals Leuven, Campus Gasthuisberg, Leuven, [4]Hematology, Ziekenhuis Netwerk Antwerpen, Antwerp, Belgium, [5]Hematology, Inselspital, Bern University Hospital, Bern, [6]Hematology, University Hospital Zürich, Zurich, Switzerland, [7]Immunology, Erasmus University Medical Center, Rotterdam, [8]Clinical Chemistry, Medisch Spectrum Twente/Medlon, Enschede, [9]Hematology, Erasmus University Medical Center, Rotterdam, Netherlands

Background: Despite up-to-date risk algorithms, outcome in acute myeloid leukemia patients is still difficult to predict. Even in good risk patients relapses occur. Further refinement of currently used risk classifications is therefore warranted. Measurable residual disease (MRD) is a well-known risk factor and the independent prognostic impact of MRD was shown for patients independent on risk groups. Nowadays prospective studies are designed on which therapy is adapted based on MRD-positivity or negativity. Although this is a major improvement for risk stratification, relapses occur in a substantial proportion of MRD-negative patients. Previous retrospective studies have shown that the leukemic stem cell (LSC) frequency harbors important prognostic information as well (Bradbury *et al.*, Leukemia 2015), even within MRD-negative patients (Terwijn *et al.* Plos one, 2013).

Aims: In this study we used data of the HOVON/SAKK H102 trial to prospectively define, using flow cytometry, the leukemic CD34+CD38- stem cell frequencies and MRD frequencies to investigate impact on patient outcome.

Methods: In 242 patients who achieved morphologic complete remission, both LSC and MRD data after two cycles of chemotherapy treatment were available. MRD-positivity was defined as a percentage of MRD-positive cells above 0.1% (as compared to total amount of WBCs) and LSC-positivity was defined as a CD34+CD38-LSC percentage above 0.0000% (LSC cut-off 0.0000%; thus no CD34+CD38-LSC events measured).

Results: Cumulative incidence of relapse (CIR) and overall survival (OS) data were investigated for four different MRD/LSC groups: 1. MRD^{neg} +LSC^{neg}patients (n=136) 2. MRD^{pos} +LSC^{neg} patients (n=28) 3. MRD^{neg} +LSC^{pos}patients (n=58) and 4. MRD^{pos} +LSC^{pos} patients (n=20). Results showed that MRD^{pos} +LSC^{pos}patients have the worst prognosis. 3-year CIR for the four above-defined groups was 35% (SE 4), 43% (SE 9), 53% (SE 7), and 100% (SE 0), respectively. Similar results were found for OS: 3-year OS was 66% (SE 4), 68% (SE 9), 53% (SE 8), and 100%, respectively, with 17 patients dead and 3 censored in the latter group. When investigating the impact of MRD/LSC status in the good, intermediate, poor and very poor risk group (according to HOVON), patient numbers were sometimes small; however, results show that MRD^{pos} +LSC^{pos}AML patients in all different risk categories have a very poor prognosis. Moreover, multivariate analyses, containing all well known risk factors including risk group and post remission treatment, showed that MRD^{pos} +LSC^{pos}patients have a significantly worse cumulative incidence of relapse (hazard ratio [HR] 5.89; 95% CI 3.32-10.47) and overall survival (HR 3.62; 95% CI 1.86-7.04) as compared to the MRD^{neg} +LSC^{neg} patient group.

Summary/Conclusions: Overall, we conclude that our prospective results show that CD34+CD38-LSC frequency has important additional value in MRD assessment and that it especially enables to identify very poor risk patients in

all different currently used risk categories. These data urge to include both MRD and LSC in future AML risk classification to better inform post-remission treatment.

DEFINITION OF PARTIAL RESPONSE IN YOUNGER AML PATIENTS AFTER FIRST INDUCTION COURSE MAY BE EXTENDED BY INCLUSION OF IMMUNOPHENOTYPIC DETECTION OF MEASURABLE RESIDUAL DISEASE IN CR

S. Freeman[1,*], D. Grimwade[2], R.K. Hills[3], P. Virgo[4], N. Khan[1], S. Couzens[5], A.F. Gilkes[6], I. Thomas[3], A.K. Burnett[7], N.H. Russell[8]
[1]Institute of Immunology and Immunotherapy , University of Birmingham , Birmingham , [2]King's College London School of Medicine, London, [3]Centre for Trials Research, Cardiff University, Cardiff, [4]North Bristol NHS Trust, Bristol, [5]University Hospital of Wales, [6]Cardiff University School of Medicine, Cardiff, [7]Isle of Arran, Isle of Arran, [8]Nottingham University Hospital, Nottingham , United Kingdom

Background: In AML response by morphology after a first cycle of induction therapy is used to guide further therapy including second cycles of induction and choice of consolidation. It is still uncertain how the quality of response post cycle 1 with inclusion of MRD assessment impacts on outcomes within AML risk subgroups including *NPM1* wild type standard risk and whether this adds information to MRD status in CR post cycle 2.
Aims: To quantify the effect of MRD positivity for response after each cycle of induction therapy in younger patients with AML.
Methods: As part of the UK NCRI AML17 trial (ISRCTN: 55675535) for patients with AML or high risk MDS up to the age of 60, prospective flow cytometric MRD (MFC-MRD) monitoring was performed after each course of induction. Any level of MRD detected was considered MRD+(sensitivity thresholds: ~0.02% by tracking diagnostic leukemic aberrant phenotypes /LAIP, ~0.05-0.1% by "different-from normal" blast LAIP). Clinicians were not informed of MFC-MRD results. Following their first cycle of induction with daunorubicin/ara-C based therapy, patients were allocated a risk group by a validated score (comprising cytogenetics, WBC, age, secondary disease, blast response to cycle 1 and mutation status). Poor risk patients received intensified therapy in cycle 2 with a view of proceeding to SCT.
Results: MFC-MRD results after either induction course are available for 1555 patients randomised from 4/09-12/14 (median age 51, range 0-73). Cycle 1 (C1) response data with MFC-MRD was available for 1,400 patients. 70% achieved morphological CR at this time-point; 14% had resistant disease (RD) and 16% were in partial remission (PR) according to clinician. Of patients in CR (n=984) 56% had detectable MFC-MRD (MRD+). Excluding poor-risk patients 14% of patients did not achieve CR (7% RD, 7% PR), 51% of patients in CR were MRD+. 5 year OS for MRD- *vs* MRD+*vs* PR *vs* RD were 63% *vs* 44% *vs* 37% *vs* 25% for all patients; 69% *vs* 51% *vs* 50% *vs* 30% excluding poor risk patients and 66% *vs* 49% *vs* 49% *vs* 30% for standard risk alone (Figure 1). The similar OS in this group between CR MRD+and PR at C1 was maintained in *NPM1*wt standard risk patients and if censored at stem cell transplant. 771 patients were in CR post cycle 2 (C2) and provided MFC-MRD data. As expected, there were significant differences in 5 year OS between CR MFC MRD+*vs* CR MFC MRD- for all patients (35% *vs* 63%) and excluding poor-risk (38% *vs* 70%, n=512). Importantly post cycle 2 MFC-MRD status also differentiated OS for *NPM1*wt standard risk patients with 5 year OS of 32% *vs* 64% (P=0.002) for MRD+*vs* MRD- (Figure 1). In stratified analyses, there was some evidence that the effect of MRD positivity on OS was lower in poor-risk patients (test for trend p=0.02 for both C1 and C2). The effect of MFC-MRD status on relapse and OS appeared greater at C2 (relapse, OR 2.00(1.56- 2.55), p<0.001; survival, OR 1.80(1.42-2.28) p<0.001) than C1 (relapse, OR 1.69(1.37- 2.07), p<0.001; survival, OR 1.46(1.19-1.79) p<0.001). In patients with data for both time points, C2 MRD remained significant on OS when adjusting for C1 response. 24 patients converted from C1 MRD- to C2 MRD+, with a poor prognosis (15 relapses, 13 deaths). C1 MRD-/C2 MRD- had the best prognosis.

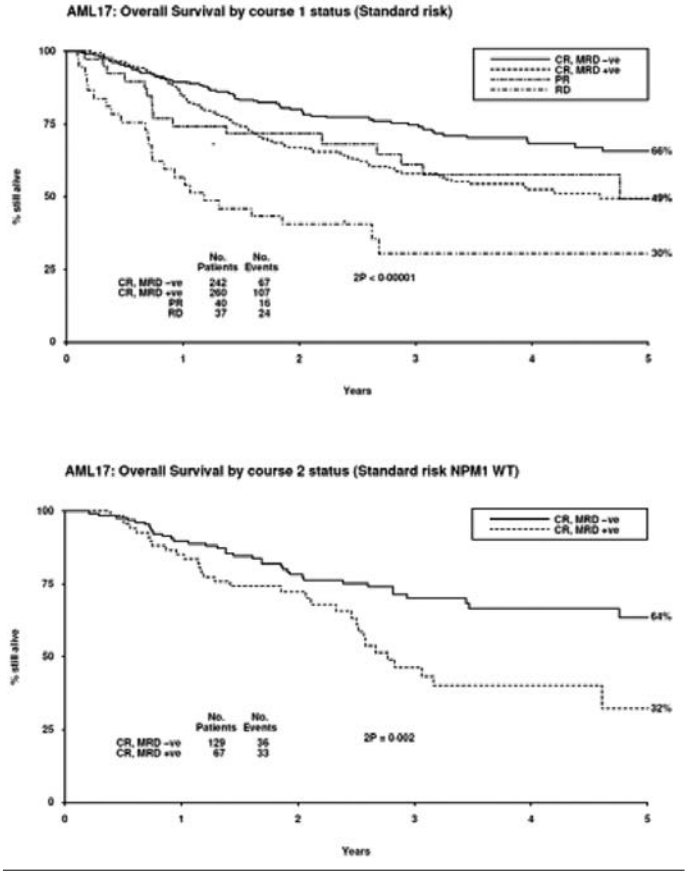

Figure 1.

Summary/Conclusions: MFC-MRD in CR post cycle 1 has similar outcomes to partial remission in younger patients with AML, particularly in patients with good and standard risk disease. Assessment of MFC-MRD post cycle 2 appears to provide additional discrimination to cycle 1: MFC-MRD in courses 1-2 may be useful in further stratifying standard risk patients.

New insights into chronic lymphocytic leukemia biology

S115

CLINICAL IMPACT OF THE SUBCLONAL ARCHITECTURE AND MUTATIONAL COMPLEXITY IN CHRONIC LYMPHOCYTIC LEUKEMIA

Background: Recent studies have revealed the presence and prognostic impact of small mutated subclones in chronic lymphocytic leukemia (CLL) (Rossi et al 2014, Nadeu et al 2016, Rasi et al 2016). Although these studies focused only on a small subset of 5 genes, their results opened a new perspective where the proportion of cells carrying each specific driver mutation may be relevant to the evolution of this disease. Moreover, the subclonal and mutational complexity estimated by the presence of subclonal driver alterations (Landau et al 2013, Landau et al 2015) or the accumulation of driver alterations (Puente et al 2015) have been proposed as promising indicators of clinical behavior.
Aims: The goal of this study was to determine the relevance of the quantitative subclonal architecture and mutational complexity in the evolution of CLL integrating the deep sequencing analysis of a large panel of driver genes and DNA copy number alterations (CNA).
Methods: The mutational status of 28 driver genes was investigated in 406 previously untreated CLL patients by targeted-deep next-generation sequencing (NGS). Mutations present in less than 1% of tumor cells were identified. All low frequency mutations were verified by allele-specific PCR or a second round of NGS. CNA were analyzed by SNP-arrays. Alterations were classified as clonal if their CCF was ≥85%, and subclonal otherwise. All patients gave informed consent.
Results: Using a highly sensitive NGS strategy we observed that small subclonal mutations were the sole alteration in 22% of the mutated cases, and were frequently detected in nearly all investigated genes. We identified three gene-specific patterns that linked the magnitude of the mutated clones (or mutated cancer cell fraction, CCF) with the prognosis of the patients: i) *CCF-independent pattern*: mutations at any CCF had prognostic value, ii) *CCF-gradual pattern*: the poor prognostic impact was a continuous variable directly related to the size of the clone, and iii) *CCF-clonal pattern*: only mutations with a CCF above a certain threshold impacted the outcome of the patients. Combining mutations and driver CNA, 86% of the patients carried at least one driver alteration, which was clonal in 66%. On the other hand, subclonal driver alterations were present in 60% of the patients. The *mutational complexity* (accumulation of 1 to ≥4 driver alterations), but not the presence of subclonal driver populations, gradually shortened the time to first treatment independently of the IGHV mutational status and Binet stage. Conversely, the *subclonal complexity,* defined as the accumulation of driver alterations with the presence of at least one driver subclone, predicted for a worse overall survival independently of the IGHV and Binet stage. Patients with a *pure clonal population* (presence of one or more driver alterations in all tumor cells) had a similar overall survival than patients without any alteration.
Summary/Conclusions: Our study shows that the prognostic impact of different driver mutations is related to the size of the mutated population. Therefore, the clinical evaluation of gene mutations should consider the quantitative representation of the mutations and not only their presence or absence. In addition, the *mutational complexity* predicts for shorter time to first treatment independently of the IGHV and Binet stage, whereas the *subclonal complexity* confers an independent adverse impact for overall survival. Altogether, the integration of the subclonal architecture and mutational complexity in prognostic indexes may improve the stratification of CLL patients.

S116

FBXW7 MUTATIONS LEAD TO ACCUMULATION OF NOTCH1, HIF1-ALPHA AND C-MYC IN CLL CELLS

V. Meyer-Pannwitt[1,2,*], S. Estenfelder[2], E. Tausch[2], S. J. Kugler[1,2], M. Reichenzeller[1,2], S. Stilgenbauer[2], D. Mertens[1,2]

[1]Department of Molecular Genetics (B061), Cooperation Unit "Mechanisms of Leukemogenesis", DKFZ, Heidelberg, [2]Internal Medicine III, Ulm University, Ulm, Germany

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with recurrent mutations that are of pathogenic and prognostic relevance. Mutations in *FBXW7* are among the most common mutations in CLL, yet their functional consequences are unknown. FBXW7 is an E3 ubiquitin ligase that ubiquitylates oncoproteins like NOTCH1, HIF1-α and c-MYC and thereby targets them for proteasomal degradation.
Aims: 2.5-4% of CLL patients harbor *FBXW7* mutations. Approximately 60% of *FBXW7* mutations alter arginine residues that are involved in substrate targeting. In T-cell acute lymphoblastic leukemia these arginine mutations are associated with chemotherapy resistance. In CLL however, the role of dysfunctional FBXW7 is unclear. We therefore aimed to delineate the prevalence of *FBXW7* mutations in CLL patient cohorts and characterize its functional role.
Methods: *FBXW7* mutations were analyzed via amplicon-based targeted next generation sequencing in primary CD19-sorted samples of previously untreated CLL patients (n=905) as well as in CLL (n=8), MCL (n=5), T-ALL (n=2), Burkitt lymphoma (n=1) and LCL cell lines (n=3). In silico modeling with PolyPhen-2 predicted a potential impact of the mutations on the structure and function of *FBXW7*. For functional analysis, *FBXW7* mutations were induced using CRISPR/Cas9 in the CLL cell line HG3, which does not harbor a *NOTCH1* mutation. Both in this CRISPR/Cas9 mutated cell line and in primary CLL cells with *FBXW7* mutations, the protein levels of FBXW7 substrates were examined. In addition, we quantified NOTCH1 and HIF1-α activity with Luciferase reporter assay in *FBXW7* mutated HG3 cell lines.
Results: Heterozygous mutations in *FBXW7* were found in 41/905 (4.5%) of CLL patients. The most common mutations of *FBXW7* were missense mutations (32/41) that target the substrate binding domain of the FBXW7 protein as well as non-sense mutations (4/41). Interestingly, 5 patients harbored two concurrent *FBXW7* mutations. By the use of the PolyPhen-2 software, all except one missense mutation in *FBXW7* were predicted to be most likely damaging. No mutations in *FBXW7* were found in the CLL, MCL and LCL cell lines analyzed. To determine the functional consequence of *FBXW7* mutations in CLL, we induced either a heterozygous or a homozygous truncation of *FBXW7* in the CLL cell line HG3, resulting in the loss of the substrate binding site of the WD40 domain. The homozygous truncation of *FBXW7* resulted in an increase of NOTCH1, HIF1-α and c-MYC protein levels, whereas no difference of Cyclin E protein amount was detectable. In addition, an elevation of NOTCH1 activity was found in both the heterozygously and homozygously truncated mutant cell lines in comparison to the wildtype HG3 cell line. To confirm this finding, protein levels of 5 CLL patients with *FBXW7* mutations were analyzed with a similar outcome.
Summary/Conclusions: Mutations in *FBXW7* are frequently found in CLL, especially missense and nonsense mutations affecting the WD40 domain. We hypothesize that this has functional consequences on FBXW7 substrate binding and hence leads to accumulation of oncogenes. In line, the induced truncation of the WD40 domain of FBXW7 in the HG3 cell line resulted in the accumulation of protein substrates and corresponding increase of their activity implicated in the pathogenesis of CLL. Taken together our data show that FBXW7 can target proteins for degradation that are commonly dysregulated in CLL and that drive disease progression.

Background: Different omics studies have focused on the analysis of individual layers of information in chronic lymphocytic leukemia (CLL), such as the genome, transcriptome and DNA methylome. However, besides the DNA methylome, other layers of the epigenome, like histone modifications, remain relatively unexplored and an integrative molecular portrait of CLL is not available yet.
Aims: The aim of this study was to extensively map and analyse the epigenome

of CLL in relation to the mutational, transcriptional and three-dimensional (3D) chromatin landscape.
Methods: Seven CLL patients with distinct clinico-pathological features and five mature B-cell subpopulations were extensively analysed using (i) ChIP-seq of six different histone marks with non-overlapping features (H3K27ac, H3K4me1, H3K4me3, H3K9me3, H3K27me3 and H3K36me3); (ii) single stranded RNA-seq; iii) transposase-accessible chromatin assays (ATAC-seq) and iv) whole-genome bisulfite sequencing (WGBS), creating a unique reference epigenome for CLL. These data were complemented with the 3D chromatin landscape in one CLL case measured by high-throughput chromatin conformation capture (HiC-seq) and promoter capture Hi-C (PCHi-C). Furthermore, we mapped the active chromatin landscape of 100 CLL patients by H3K27ac ChIP-seq and ATAC-seq. Whole-genome sequencing data was available for 44 of these patients. We applied a broad range of bioinformatic tools to analyze the data in an integrative way.
Results: CLL is distinct from normal B cells for all layers of the reference epigenome (7 CLLs) and the active chromatin landscape (100 CLLs). CLL though is closer to naive and memory B cells than to germinal center B cells and plasma cells. Interestingly, in CLL we not only saw activation of regions that are active in naive and memory B cells, but also an unexpected activation of genomic regions that are specifically active in germinal center B cells and plasma cells. Changes in activation in these and other regions could furthermore distinguish the two major clinical subgroups of CLL with unmutated and mutated immunoglobulin heavy chains (IGVH). CLLs did not only differ from normal B cells regarding the separate layers of information, but also using combined patterns of histone marks, which for example can define regulatory elements as active promoters (H3K4me3 and H3K27ac) or active enhancers (H3K27ac and H3K4me1). More specifically, we detected 534 genomic regions with *de novo* gain (n=498) or loss (n=36) of active regulatory regions in CLL. Large regions (>10kb) showing *de novo* gain of regulatory elements in CLL (n=51), were located into, close to, or interacted in 3D space with genes important for CLL pathogenesis, *e.g.*, *LEF1*, *BCL2* and *FMOD*. Interestingly, non-coding somatic mutations in IGVH mutated CLLs accumulate in these and other active regulatory regions, likely being off-target effects of the somatic hypermutation machinery. Besides changes in regulatory elements, we observed that CLLs lose poised promoters, which are replaced by repressed/inactive regions. This change, mainly occurring in developmental genes, does not affect gene expression levels, as these genes are already silent in normal B cells. It may however represent loss of plasticity during CLL pathogenesis in which these genes become permanently inactive.
Summary/Conclusions: With this integrative study, we generated new conceptual avenues to understand the complex link among the epigenetic, mutational, transcriptional and 3D chromatin landscape in CLL. In addition we provide the community with an extensive resource of epigenetic information of this lymphoid neoplasm.

S118

THERAPEUTIC DISRUPTION OF THE BAFF- B-CELL RECEPTOR CROSS-TALK IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS
C. Paiva[1], T. Rowland[1], B. Sreekantham[1], O. Danilova[1], A. Danilov[1,*]
[1]Oregon Health and Science University, Portland, United States

Background: Although small molecule inhibitors of BCR-associated kinases (BCRi) revolutionized therapy in CLL, they provide incomplete responses. Tumor necrosis factor receptor superfamily ligands BAFF and APRIL induce NFκB, which in turn upregulates pro-survival Bcl-2 family proteins and thereby drives anti-apoptotic responses, potentially accounting for resistance to BCRi. The exact roles of the individual NFκB pathways, as well as the implications of targeting BCR in context of BAFF signaling in CLL remain understudied.
Aims: We explored the mechanistic underpinnings of CLL cell survival in response to BAFF signaling.
Methods: We established a novel BAFF-expressing stromal co-culture model and employed inhibitors of Bruton tyrosine kinase (BTK, ibrutinib), phosphoinositide-3 kinase (PI3K, idelalisib) and spleen tyrosine kinase (SYK, entospletinib). We quantified CLL cell apoptosis, migration, NFκB activity, protein and mRNA expression by flow cytometry, immunoblotting, ELISA, RT-PCR and immunocytochemistry.
Results: CLL cells co-cultured with BAFF-expressing stroma were resistant to spontaneous apoptosis (12.3±3.2% after 24 h, *vs* 34.8±6.2% off stroma) and chemotherapy agents (bendamustine, fludarabine). Gene expression profiling exposed the NFκB pathway gene targets as the most significantly upregulated upon BAFF stimulation ($p<0.0001$). We and others have shown that CD40L-expressing stroma induces canonical and non-canonical NFκB in CLL. By contrast, while BAFF led to strong activation of the non-canonical NFκB with processing of p100 (to p52) by 4 h and a 5-fold increase in p52 DNA-binding activity by 24 h, canonical NFκB (RelA) activation was less pronounced. BAFF predominantly induced Mcl-1, compared to CD40L which strongly upregulated Bcl-X. BCR is a major driver of canonical NFκB signaling in CLL. Thus, we studied whether BAFF co-opted BCR signaling in CLL. BAFF induced rapid (15 min) phosphorylation of the proximal BCR kinases SYKand LYN, sustained for up to 4 h, as well as ERK, in CLL cells. AKT activation occurred late (>2 h), suggesting that BAFF induced AKT independent of BCR. BAFF-mediated BCR activation did not correlate with *IGHV* mutational status. Like IgM, BAFF induced CLL cell chemotaxis. SYK inhibition effectively antagonized survival and chemotaxis of BAFF-stimulated CLL cells. By contrast, targeting BTK or PI3K was less effective. All BCRi's fully blocked canonical NFκB activation in BAFF-stimulated CLL cells (suggesting its dependence on BCR signaling), but none inhibited the non-canonical pathway. By contrast, pevonedistat, an inhibitor of Nedd8-activating enzyme which we have previously shown to abrogate TNFR-mediated NFκB activation, blocked both canonical and non-canonical NFκB activity in BAFF-simulated CLL cells. SYK inhibitor entospletinib, but not other BCRi's, decreased Mcl-1 expression in CLL cells co-cultured with BAFF-expressing stroma and abrogated BAFF-mediated upregulation of pSTAT3, a transcription factor which regulates Mcl-1. This was accompanied by a decrease in Mcl-1 transcript. BAFF receptor signals via the TRAF complex to induce non-canonical NFκB activation in neoplastic B-cells. We supposed that TRAF complex could be directly responsible for SYK activation by BAFF. Indeed, IP experiments demonstrated that SYK directly complexed with TRAF2/3 in BAFF-stimulated neoplastic B-cells.
Summary/Conclusions: Thus, BAFF-mediated induction of BCR-associated kinases and Mcl-1 contributes to CLL cell survival. SYK inhibition is a promising therapeutic strategy uniquely poised to antagonize crosstalk between BAFF and BCR, thereby disrupting the pro-survival microenvironment signaling in CLL.

Pathogenesis of MDS

S119

LOW MYBL2 EXPRESSION OBSERVED IN MYELODYSPLASTIC SYNDROME PATIENTS WITH WORSE PROGNOSIS IS ASSOCIATED WITH ALTERED DNA REPAIR MECHANISMS IN HAEMATOPOETIC STEM CELLS

R. Bayley[1], L. Cancian[1], C. Ward[1], G. Volpe[1], S. Dumon[1], J. Gujar[1], G. Stewart[1], E. Petermann[1], P. Garcia[1,*]
[1]Institute of Cancer and Genomic Science, University of Birmingham, Birmingham, United Kingdom

Background: MYBL2 is a transcription factor with roles in the cell cycle and genome integrity. *MYBL2* is located on chromosome 20, within a region commonly deleted in human blood disorders (del20q). Our published data shows that reduced levels of MYBL2 predispose to development of myelodysplastic syndrome (MDS)-like disease in mouse models during ageing, indicating that MYBL2 could be acting as a tumour suppressor gene within del20q abnormality. Moreover, our previous work demonstrated that regardless of del20q deletion, MYBL2 expression is reduced in $CD34^+$bone marrow cells from MDS patients with worse prognosis. Because it has been shown that the cell of origin of MDS is the haematopoietic stem cell (HSC) and given the role of MYBL2 in DNA replication fork progression and maintenance of genome integrity, we hypothesised that low MYBL2 levels in HSC could contribute to elevated somatic mutations through changes in DNA repair pathways and drive disease development.
Aims: The aim of this study was to determine if low MYBL2 levels affect the double strand break (DSB) DNA repair damage response in HSC.
Methods: In this study we used our mouse model in which animals express ~50% normal levels of MYBL2 ($Mybl2^{+/\Delta}$). We characterised the ability of HSCs from young (7 weeks) and old (70 weeks) animals to respond to *in vivo* ionising radiation (2Gy) in terms of proliferation, apoptosis and colony forming ability. We measured the activation of the two main DNA repair pathways operating in the cells to deal with DSB: the error prone non-homologous-end-joining (NHEJ) and the error-free homologous recombination (HR) by assessing 53BP1 and Rad51 recruitment by immunofluorescence, respectively. Finally, we analysed the frequency of chromosome abnormalities present in the progeny of $Mybl2^{+/\Delta}$ HSC that have previously been irradiated to determine the long term effects of changes in DNA repair.
Results: We observed that $Mybl2^{+/\Delta}$ HSCs had limited proliferative potential and displayed an increased sensitivity to ionizing radiation which increased during ageing. $Mybl2^{+/\Delta}$ HSCs also displayed altered kinetics of 53BP1 and Rad51 recruitment and clearance, including retention of 53BP1 foci at later time points following irradiation and decreased levels of Rad51 foci when compared to $Mybl2^{+/+}$HSCs. Using plasmid functional assays, we showed that $Mybl2^{+/\Delta}$ HSCs repair quite efficiently by NHEJ, but this efficiency is disrupted when cells are challenged with ionising radiation. Furthermore, $Mybl2^{+/\Delta}$ HSCs have increased sensitivity to inhibition of DNA-PKC (required for NHEJ) but not ATM (required by HR). We also observed that after ionizing irradiation $Mybl2^{+/\Delta}$ HSCs progeny displayed an increased percentage of chromatids with fragile telomeres. Moreover, by making use of publically available RNA-seq datasets from MDS patients, we have identified a clear association between low MYBL2 levels and low expression of DNA-repair genes in patients with worse prognosis.
Summary/Conclusions: In summary, we have shown that decreased expression of MYBL2 leads to an imbalance in the DSB DNA-repair pathway choice, ultimately resulting in increased genomic instability of the blood cell progeny. These findings are supported by a signature of deregulated DNA-repair genes which strongly associates with low MYBL2 levels in MDS patient samples, providing a mechanistic understanding for the progression of blood disorders occurring during ageing. This study demonstrates a novel role for MYBL2 in DSB repair in HSCs and suggests that low levels of MYBL2 in human MDS could contribute to the emergence of further genetic abnormalities by deregulation of DNA-repair pathways.

Background: Clinical heterogeneity of myelodysplastic syndromes (MDS) and related myeloid neoplasms reflects molecular diversity. Most common genetic associations with distinct clinical or pathomorphologic phenotypes have been already reported, but many other common somatic lesions exist and their clinical context still remains elusive. AT rich interactive domain 2 (*ARID2*), which is located on chromosome 12q, encodes a component of the SWI/SNF complex that is involved in chromatin remodeling. In recent years multiple groups detected *ARID2* mutations in a variety of solid tumors.
Aims: Here, we present whole exome sequencing-guided identification of novel *ARID2* mutations in myeloid neoplasms. Specifically, in addition to copy number analysis and deep targeted and exome sequencing, here we include RNA sequencing and splicing analyses of the roles of spliceosomal mutations in *ARID2* missplicing and gene expression.
Methods: Bone marrow aspirates or blood samples were collected from 1,473 patients with MDS (n=455), myelodysplastic/myeloproliferative neoplasms (MDS/MPN) (n=201), myeloproliferative neoplasms (MPN) (n=56), sAML (n=221), and primary acute myeloid leukemia (pAML) (n=540) at the Cleveland Clinic and The University of Tokyo; the registered data at The Cancer Genome Atlas were also included. Diagnoses were classified using World Health Organization criteria. Informed consent for sample collection was obtained according to a protocol approved by each Institutional Review Board in accordance with the Declaration of Helsinki.
Results: By comprehensive genetic investigation of these cases, we characterized here cases (10%) in which decreased expression of *ARID2* mediated their clinical effects in MDS and other myeloid neoplasms via multiple kinds of genetic lesions. We showed that insufficient *ARID2* expression mainly in MDS arose from *ARID2* mutations, deletions, and missplicing due to *U2AF1* mutations that yielded defective *ARID2* transcripts. Clonal architecture analyses showed that *ARID2* mutations and deletions occurred as initial events of MDS or myelodysplastic/myeloproliferative neoplasms, and not during progression to acute myeloid leukemia. Morphologically, progressive maturation in myeloid and erythroid lineages and hypolobated megakaryocytes (indicated by arrow heads in Figure 1) were common in cases with *ARID2* mutations and deletions, and were also found in cases with *U2AF1* mutations. Functionally, we utilized *in vitro* knockdown models of *ARID2* expression in hematopoietic cell lines and bone marrow mononuclear cells. Since no homozygous deletion or mutation of *ARID2* was identified, we transduced shRNA in neoplastic and healthy hematopoietic cells to obtain disease models with partial reduction of *ARID2* expression. Two myeloid cell lines (HL60 and K562) in which *ARID2* expression was knocked down showed significantly lower cell counts compared to those with normal *ARID2* expression, compatible with more apoptotic cells in knockdown experiments. Flow cytometric analysis of the cell lines with reduced *ARID2* expression revealed increased cell-surface maturation markers, CD11b and glycophorin A (GPA), suggesting that reduced expression of *ARID2* resulted in more differentiation in myeloid and erythroid lineages. Knockdown of *ARID2* failed to reduce colony formation in bone marrow mononuclear cells. These results indicate that reduced *ARID2* expression might induce more differentiation in myeloid/erythroid lineages and more apoptosis to reduce cell populations without reduction of proliferation capacity in hematopoietic progenitor cells. Finally, we examined morphological findings associated with knockdown *ARID2* expression. Compared to control cells, K562 cells with reduced *ARID2* expression formed more hypolobated megakaryocytes, which confirmed morphological findings seen in *ARID2* and *U2AF1* defects.

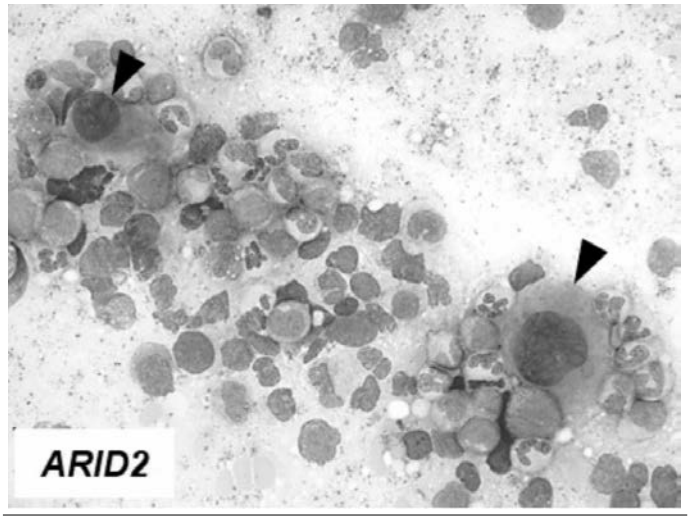

Figure 1.

Summary/Conclusions: *ARID2* is a MDS-suppressor gene whose expression is attenuated by multiple mechanisms as it shapes the distinct morphological phenotype of a subset of myelodysplasia.

THE VALUE OF NGS PANEL SEQUENCING TO MOLECULARLY DEFINE MYELOID MALIGNANCIES AND CLARIFY BORDERLINE CASES: A STUDY ON 39 GENES IN 1143 PATIENTS

C. Baer[1,*], K. Perglerová[2], W. Kern[1], C. Haferlach[1], T. Haferlach[1]
[1]MLL Munich Leukemia Laboratory, Munich, Germany, [2]MLL2 s.r.o., Prague, Czech Republic

Background: The 2016 revision of the WHO classification for myeloid malignancies includes numerous molecular markers for classification and prognostication. Next generation sequencing allows analyzing relevant genes in one panel.
Aims: Exploit clinical usefulness of panel sequencing in routine diagnostics in order to describe genetic changes and use respective patterns in cases with undefinitive morphology.
Methods: According to WHO 2016, 1143 patients were morphologically categorized as AML (n=261), MDS (n=176), MPN (n=19), CMML (n=51) or AML/MDS (n=21) and MDS/MPN overlap (n=28). Patients, who did not fulfill all characteristic criteria or had insufficient sample quality, were classified as "possible" AML (n=28), MDS (n=211), MPN (n=5), CMML (n=14) and as reactive (n=193) or unclear (n=136). DNA was isolated from BM (n=958) or PB (n=185) for NextSeq or MiSeq sequencing after TruSeq library preparation (all Illumina, San Diego, CA). Data was analyzed with SeqNext 4.3 (JSI Medical Systems, Kippenheim, Germany). *FLT3*-ITD and *KMT2A*-PTD data was obtained according to standard protocols.
Results: Analyzing 39 genes, we found ≥1 molecular change in 90% of patients (500/556) with a definite morphologic diagnosis (median: 2 genes; max: 7).
In de novo AML, 212/229 (93%) patients showed ≥1 molecular hit, of which 211 (92%) had aberrations that define WHO categories or have prognostic (according to ELN/MRC) or predictive value. More than one mutation was found in 166/229 patients (72%), including information of adverse impact (*e.g.* of 68 *NPM1* positive patients, 17 had *DNMT3A* mutations and 20 *FLT3*-ITD). Following *NPM1*, *RUNX1* was the second most frequently mutated gene (46/225; 20%) and mutations were significantly more common in patients with ≥3 aberrations (38/104; 37% *vs* 8/96; 8%; p<0.001). A similar *RUNX1* pattern was found in s-AML and t-AML. In the cohort of "possible AML" (including MDS overlap), 45/48 (94%) patients had ≥1 hit. Most frequently mutated were *ASXL1* (16/48; 33%), *TET2* (32%; 14/44) and *SRSF2* (29%; 14/48); 16% had all three mutated. This combination is also the most frequent three-way interaction in CMML (10/44; 23%). In MDS, 124/157 (79%) cases showed mutations, of which 108 had ≥1 prognostic change (according to Bejar, 2015). The prognostically favorable *SF3B1* mutation was present in 31/157 (20%) and significantly enriched among cases with ring sideroblasts (p<0.001). Overall, *TET2* showed the highest mutation rate (25%) and was also the most commonly mutated gene in cases with "possible" MDS (36/190; 19%), reactive morphologic changes (17/201; 8%) or even unclear morphology (19/116; 17%). Of these three subsets, five patients had only the *TET2* mutation with <10% burden, which is observed in clonal hematopoiesis of indeterminate potential (CHIP), too. However, using panel sequencing in cases with possible MDS, unclear or reactive morphology revealed at least one molecular marker for clonal disease in 47% (91/199), 36% (43/118) or 17% (36/211) of cases, respectively (excluding sole *ASXL1*, *DNMT3A*, *TET2* mutations with <10% burden).
Summary/Conclusions: WHO 2016 requires information on numerous genes for diagnosis, prognosis and therapeutic decisions. This challenges conventional laboratory approaches and suggests panel sequencing. We demonstrate the feasibility in routine settings for a broad spectrum of myeloid malignancies and identify 1) relevant patterns and mutation interactions; 2) genetic aberrations supporting diagnosis for samples with borderline morphology or poor quality and 3) patient-specific clonality useful for follow-up.

Background: The myelodysplastic syndromes (MDS) are disorders of the hematopoietic stem cell (HSC) and patients suffer from anemia and other cytopenias and show increasing bone marrow blasts over time. Mutations in spliceosomal genes (including *SF3B1*, *SRSF2* and *U2AF1*) occur in >50% of MDS patients.
Aims: We aimed to identify the deregulated pathways and gene ontology (GO) categories associated with aberrantly spliced genes in CD34+cells and in differentiated cells of MDS-affected lineages isolated from the bone marrow of MDS patients harboring spliceosome mutations.
Methods: Transcriptome data were generated using RNA sequencing (RNA-seq) and splicing factor mutant cases were compared to wildtype cases and to healthy controls. Aberrant (including cryptic) splicing events were identified using rMATS. Deregulated pathways and GO themes were identified using Ingenuity Pathway Analysis and GOseq.
Results: RNA-Seq was performed on CD34+cells obtained from the bone marrow of 91 MDS patients (including 28, 8 and 6 cases with *SF3B1, SRSF2* or *U2AF1* mutations, respectively) and 8 healthy controls. The aberrant splicing events associated with each mutated splicing factor tended to affect different sets of genes, although some overlap was observed. GO analysis of the aberrantly spliced genes associated with *SF3B1*, *SRSF2* or *U2AF1* mutations showed a marked convergence of significantly enriched ontology themes: 26 of the top 30 most significant GO categories, including 'RNA splicing' and 'translation', in the comparison of mutant cases for each splicing factor gene to healthy controls (18 of 30 in the comparison to wildtype cases) were common to all three mutated splicing factor genes. Pathway analysis revealed deregulated pathways (*e.g.* 'oxidative phosphorylation' and 'mitochondrial dysfunction') that were common to more than one mutated gene (*i.e. SF3B1* and *SRSF2*), and pathways specific for one mutated splicing factor gene (*e.g.* 'protein ubiquitination' in *SF3B1* mutant cases). An analysis of upstream transcriptional regulators showed a significant overlap between the aberrantly spliced genes associated with each mutant splicing factor gene (in the comparison to both wildtype cases and to healthy controls) and genes regulated by several transcription factors, including E2F1. RNA-Seq was also performed on CD34+cells and on differentiated erythroid, granulocytic and monocytic cell populations isolated from the bone marrow of each of 7 *SF3B1* mutant MDS cases, 7 wildtype cases and 5 healthy controls, in order to explore similarities/differences between aberrantly spliced genes and deregulated pathways and GO themes in cells of different lineages. There were many aberrantly spliced genes in one cell population that did not overlap with aberrantly spliced genes in other populations. A small proportion (*i.e.* <5%) of aberrantly spliced genes were common to all four cell populations. GO analysis of the aberrantly spliced genes identified showed that 6 of the top 30 most significant categories (including 'RNA binding' and 'translation') in the comparison of *SF3B1* mutant cases to healthy controls (4 of 30 in the comparison to wildtype cases) were common to all four cell populations studied. Pathway analysis revealed that several pathways were deregulated in specific cell populations (*e.g.* 'mTOR signaling' in erythroid cells), and some pathways (*e.g.* 'EIF2 signaling', involved in protein synthesis initiation) were deregulated in all four cell populations studied.
Summary/Conclusions: Our study has identified aberrantly spliced genes and deregulated pathways associated with spliceosome mutations in the HSCs and the major cell lineages affected in MDS, providing new insights into how these mutations impact cellular processes in this disorder.

Background: Myelodysplastic syndromes (MDS) and related myeloid disorders ("myelodysplasia") are a heterogeneous group of clonal hematopoietic disorders with a highly variable clinical outcome.
Aims: The purpose of this study was to establish a novel gene expression-based classification of myelodysplasia for better prognostication.

Methods: We performed transcriptome sequencing of bone marrow mononuclear cells (BMMNCs) and/or CD34+cells obtained from patients with myelodysplasia. Consensus clustering was used to identify stable patient clusters. A classifier of the gene expression-based subgroups was constructed using the 100 CD34+cell samples as a training set, followed by validation in an independent cohort of 183 MDS patients. Another classifier was constructed using BMMNC samples from 51 patients, who had been assigned to the subgroups by the gene expression data of their CD34+cells. Prognostic significance of the model was tested in 114 patients of myelodysplasia.
Results: Unsupervised clustering of gene expression data of bone marrow CD34+cells from 100 patients identified two subgroups (Class-I and Class-II). The patients in the Class-II subgroup had higher percentages of bone marrow blasts compared to those in the Class-I subgroup (median 2% *vs* 11%, *P* <0.001). Pathway analysis revealed up-regulation of many signaling pathways in the Class-II subgroup. The Class-I subtype showed highly significant up-regulation of the genes related to erythroid lineages. The erythroid signature was rather suppressed in the Class-II subtype, which was characterized by increased expression of genes related to progenitor cells. Compared to the Class-I subtype, the Class-II subtype was associated with a significantly shorter survival in both univariate (hazard ratio [HR] 5.0 [95% CI, 1.8–14], *P* <0.001) and multivariate analysis (HR 6.8 [95% CI, 1.5–32], *P*=0.015). High frequency of leukemic transformation in the Class-II subgroup (38%) contrasted to no leukemic transformation in the Class-I subgroup. The prognostic significance of our classification was validated in an independent cohort of 183 patients. We also constructed a model to predict the subgroups using gene expression profiles of BMMNCs. The model was applied to 114 patients with BMMNC samples, of whom 47 (41%) were predicted to be the Class-II subgroup. Compared to the predicted Class-I subgroup, the Class-II subgroup was associated with a significantly shorter survival in univariate analysis (HR 7.2 [95% CI, 3.0–17], *P* <0.001). Again, association was more pronounced for leukemic transformation (HR 18 [95% CI, 4.2–80], *P* <0.001) than for overall survival. Multivariate analysis also demonstrated that the predicted Class-II subgroup was independently associated with leukemic transformation (HR 7.3 [95% CI, 1.3–41], *P*=0.024). Finally, we compared the prognostic value of our model with that of the LSC17 score, which has recently been proposed to predict a subset of poor risk acute myeloid leukemia based on the expression of 17 genes related to a leukemic stem cell signature. Our model outperformed the LSC17 score in predicting clinical outcomes of myelodysplasia, especially leukemia progression. The Class-II signature was shown to be more dramatically up-regulated during clonal evolution of myelodysplasia than the LSC17 score, which might be the basis of a better prediction of leukemia progression in our model.
Summary/Conclusions: Comprehensive transcriptomic analysis identified two subgroups of myelodysplasia with biological and clinical relevance, which could improve risk prediction and treatment stratification of myelodysplasia.

GENETIC ALTERATIONS INVOLVING PROGRAMMED DEATH LIGANDS IN EPSTEIN-BARR VIRUS-ASSOCIATED LYMPHOMAS

K. Kataoka[1,*], M. Hiroaki[2], S. Sakata[3], A. Dobashi[3], L. Couronné[4], Y. Kogure[1], Y. Sato[5], K. Nishida[5], Y. Shiraishi[6], H. Tanaka[6], K. Chiba[6], Y. Watatani[1], Y. Shiozawa[1], K. Yoshida[1], M. Sanada[7], M. Kato[8], S. Miyano[6], Y. Ota[9], K. Izutsu[10], T. Yoshino[5], O. Hermine[4], K. Takeuchi[3], K. Ohshima[2], S. Ogawa[1]
[1]Department of Pathology and Tumor Biology, Kyoto University, Kyoto, [2]Department of Pathology, Kurume University School of Medicine, Kurume, [3]Pathology Project for Molecular Targets, Cancer Institute, Tokyo, Japan, [4]Clinical Hematology, Imagine Institute, Paris, France, [5]Department of Pathology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, [6]Laboratory of DNA Information Analysis, The University of Tokyo, Tokyo, [7]Department of Advanced Diagnosis, Nagoya Medical Center, Nagoya, [8]Department of Pediatric Hematology and Oncology Research, National Centre for Child Health and Development, [9]Department of Pathology, [10]Department of Hematology, Toranomon Hospital, Tokyo, Japan

Background: Checkpoint blockade using anti-PD-1/PD-L1 antibodies is a highly promising therapy for cancer, frequently showing dramatic anti-tumor responses in a wide variety of tumor types. Particularly, an exceptional response to anti-PD-1 antibodies has been demonstrated for classical Hodgkin lymphoma (HL), which is characterized by frequent copy number gains/amplifications involving *PD-L1* and/or *PD-L2*, suggesting a close link between *PD-L1/PD-L2* genetic alterations and the therapeutic response to these agents. Recently, we have reported frequent structural variations (SVs) in adult T-cell leukemia/lymphoma (ATL) caused by human T-cell leukemia virus type-1 (HTLV-1). These SVs invariably affect 3′-untranslated region (UTR) of *PD-L1*, leading to prominent *PD-L1* overexpression. Providing that viral antigens induce potent cellular immunity to virally infected cells, we hypothesized that a deregulated PD-1/PD-L1 axis might play a critical role in evasion from anti-viral immunity before these cells are clonally selected for neoplastic proliferation.
Aims: Epstein-Barr virus is a DNA tumor virus closely associated with various human cancers, including B- and natural killer (NK)/T-cell lymphomas, in which genetic alterations involving *PD-L1/PD-L2* may also be relevant to cancer evolution. In this study, to assess this hypothesis, we interrogated a variety of lymphomas for genetic abnormalities affecting *PD-L1* and *PD-L2*, especially focusing on EBV-associated lymphomas.
Methods: SVs and other genetic lesions affecting *PD-L1* and *PD-L2* were analyzed using targeted-capture sequencing with cRNA baits designed for capturing the entire sequences of *PD-L1* and *PD-L2* genes, including exons, introns, and 5′- and 3′-UTRs. More than 400 samples were analyzed obtained from different subtypes of non-Hodgkin lymphomas, including EBV-associated lymphomas, such as EBV-positive diffuse large B-cell lymphoma (DLBCL) and NK/T-cell malignancies.
Results: SVs and/or focal copy number gains involving PD ligands were successfully detected in various B-cell and T/NK-cell lymphomas, albeit at generally low frequencies (<10%). These lesions were the most frequently observed in PMBCL, accounting for more than 60% of the cases. Of note, high frequency (17−57%) of *PD-L1/PD-L2*-involving abnormalities were observed in mature NK/T-cell neoplasms, including extranodal NK/T-cell lymphoma, aggressive NK cell leukemia, and EBV-positive T-cell lymphoproliferative disorder, all of which were positive for EBV. Moreover, a substantial proportion (22%) of EBV-positive DLBCL cases possessed these lesions, whereas EBV-negative cases rarely exhibited these alterations (2%, P<0.01). For both *PD-L1* and *PD-L2* SVs, despite a large diversity of SV type (deletions, inversions, tandem duplications, and translocations), most of SVs resulted in 3'-UTR truncation, while the replacement of *PD-L1* or *PD-L2* promoter with an ectopic regulatory element was rarely observed. Interestingly, *PD-L1* SVs were detected in both B- and T-cell lymphomas, whereas *PD-L2* SVs were found exclusively in B-cell lymphomas.
Summary/Conclusions: We delineate the entire picture of genetic alterations involving PD ligands, and confirm the close association between these lesions and EBV-associated lymphomas. Our finding help to understand their pathogenesis and develop a new diagnostic strategy to identify patients who potentially benefit from PD-1/PD-L1 blockade therapy in non-Hodgkin lymphomas.

FOXO1 CONTROL CD20 EXPRESSION AND INFLUENCE B-CELL LYMPHOMA RESPONSE TO RITUXIMAB-BASED IMMUNOTHERAPY

M. Dwojak[1,*], B. Pyrzynska[1], A. Zerrouqi[1], G. Morlino[2], P. Zapala[1], N. Miazek[1], K. Bojarczuk[1], M. Bobrowicz[1], M. Machnicki[1], J. Golab[1], D. Calado[2], M. Winiarska[1]
[1]Department of Immunology, Medical University of Warsaw, Warsaw, Poland, [2]The Francis Crick Institute, London, United Kingdom

Background: Recurrent somatic mutations of N-terminal region of FOXO1,

shown previously to increase FOXO1 nuclear localization and activity, have been linked to diminished survival in DLBCL patients uniformly treated with rituximab-based immunotherapy. Although the contribution of FOXO1 mutations to the therapeutic resistance of B-NHLs becomes apparent, the molecular mechanism underlying this phenomenon has not been explained so far. The diminished levels of CD20 on the cell surface of tumor cells are among several potential mechanisms underlying the resistance to treatment with anti-CD20 monoclonal antibodies.

Aims: We have recently reported that the tonic BCR signaling activates FOXO1, and that inhibitors of the downstream BCR signaling pathways downregulate CD20 expression. Therefore, here we sought to determine whether FOXO1 might regulate the abundance of CD20 on the surface of tumor cells thus influencing the response to rituximab-based therapies.

Methods: We used CRISPR/Cas9 genome editing technology and lentiviral transduction to study the role of FOXO1 protein in CD20 regulation. qRT-PCR and Dual Luciferase Assays was done to determine the influence of FoXO1 on CD20 transcription. To get insight into molecular interaction between FOXO1 and CD20 promoter we performed EMSA and ChIP experiments. For animal studies we used SCID Fox Chase mice model. All *in vivo* experiments were carried out at the animal facility of The Francis Crick Institute in accordance with the guidelines and were approved by the Ethics Committee.

Results: To determine the potential role of FOXO1 protein in CD20 regulation, we disrupted *FOXO1* locus using the CRISPR/Cas9 genome editing technology in Raji cells. In *in vitro* complement-dependent cytotoxicity assay we show that ablation of FOXO1 results in upregulation of CD20 levels and improvement of rituximab efficacy. To see whether FOXO1-dependent up-regulation of CD20 translates into improved antitumor efficacy of rituximab *in vivo* we have used SCID Fox Chase mice model. We found that mice treated with systemic rituximab survived longer when inoculated with sgFOXO1-transduced Raji cells as compared with mice inoculated with control Raji cells. Consistently, using clinically tested PI3K-AKT inhibitors - MK-2206 and GDC-0068 – in a set of CLL primary samples we show that also pharmaceutical inhibition of FOXO1 activity upregulated surface CD20 levels. Moreover, we demonstrated that FOXO1 regulate the CD20 promoter activity. In different B-cell lymphoma cell lines MK-2206 and GDC-0068 significantly downregulated the levels of *MS4A1* transcript (encoding CD20). Finally, using both EMSA and ChIP assays we detected specific binding of FOXO1 to the *MS4A1* promoter to the extent comparable to other known FOXO1 target genes.

Summary/Conclusions: Collectively, our results indicate that FOXO1 is strong negative regulator of CD20 expression and add new insights into the mechanisms underlying the contribution of *FOXO1* mutations to the resistance of B-NHLs to R-CHOP therapy. In light of current knowledge and our observations presented in this study, FOXO1 inhibition represents a novel strategy to increase the efficacy of anti-CD20 monoclonal antibodies.

S126

ALPHA-KETOGLUTURATE EXPOSES METABOLIC VULNERABILITIES IN B-CELL LYMPHOMAS

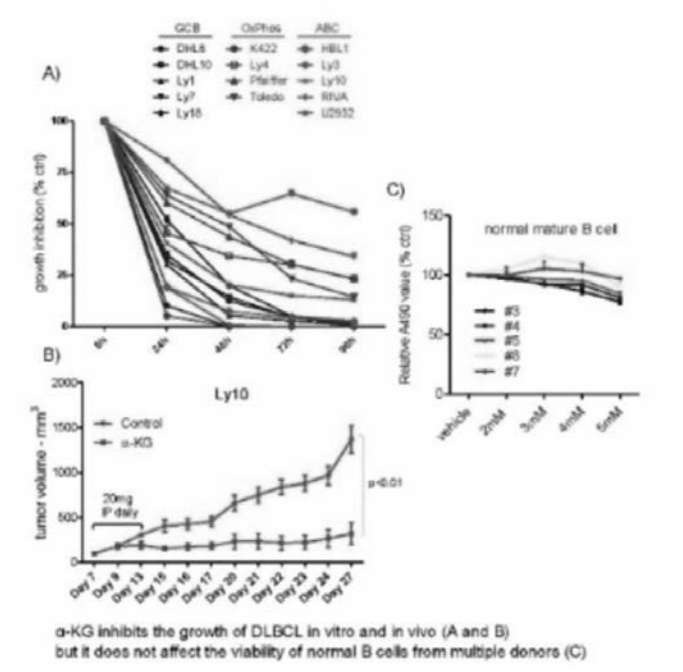
D. Jiang[1], A.-P. Lin[1], L. Wang[1], R. Aguiar[1,*]
[1]Hematology/Oncology - Medicine, University of Texas Health Science Center, San Antonio, United States

Background: Metabolic rewiring is a cancer hallmark. These metabolic changes can be secondary to a broader oncogenic-driven deregulation (*e.g.*, MYC), or they may be more specific and result from mutations in enzymes (*e.g.*, IDH1 and IDH2) that directly control energy flux in the cell. Mutant IDH acquires a neomorphic activity and aberrantly generates high levels of D2-hydroxyglutarate (D2-HG), a natural metabolite with marked structural similarity to alpha-ketoglutarate (α-KG). D2-HG functions as an oncometabolite by competitively inhibiting the activity of multiple α-KG-dependent dioxygenases, including TET DNA hydroxylases and JmJC HDMs. The role of a D2-HG/α-KG metabolic imbalance in cancer was expanded by our recent discovery of somatic loss-of-function mutations in D2HGDH in diffuse large B cell lymphomas (DLBCL) (Nat Commun. 2015 Jul 16; 6:7768). D2HGDH catalyzes the conversion of D2-HG into α-KG, and D2HGDH -mutant DLBCLs display deficiency of α-KG with attending impaired dioxygenase function. Together, these data suggest that while D2-HG is an oncometabolite, α-KG may function as tumor suppressive metabolite.

Aims: To explore the concept that α-KG has tumor suppressor activities, and to characterize the signaling nodes that mediate the anti-lymphoma activity of this intermediated metabolite.

Methods: We utilized a panel of 14 well-characterized DLBCL cell lines to test the growth suppressive activity of cell-permeable synthetic α-KG derivative, dimethyl-α-KG (DM-KG), using cell proliferation and apoptosis assays. The cell line data was expanded to primary mature B cell tumors as well as normal B cells. These *in vitro* assays were complemented by xenografts models of human DLBCL. Functional studies were performed in cell lines and primary tumors, and included the enzymatic quantification of ATP synthase activity, the effects of α-KG on cellular ATP levels, the measurement of AMPK activity and of the mTORC1 kinase.

Results: The cell-permeable DM-KG induced a marked dose-dependent growth suppression in a panel of DLBCL cell lines that encompasses the molecular heterogeneity of this disease (ABC, n= 5, GCB, n=5 and OxPhos, n=4). In most instances, the growth inhibition exceeded 80% of vehicle control exposed cells and it could be detected as early as 24h and reached its peak at 72-96h post-exposure (Figure 1A). In all cell lines examined, induction of apoptosis accounted for most of the anti-lymphoma effects of DM-KG. There was no clear segregation between the DLBLC molecular subtype and DM-KG-induced growth inhibition (*e.g.*, the ABC cell lines Ly10 and Ly3 were the most sensitive and most resistant, respectively, Figure 1A). Remarkably, we found that normal mature B cells (murine and human) were resistant to growth inhibition and apoptosis induced by DM-KG (Figure 1C). Contrary to that, exposing viable primary CLL, FL and DLBCL cells to DM-KG significantly induced apoptosis ($p<0.01$) in all tumors examined (n=17). In xenograft models of GCB- or ABC-DLBCLs (Ly7 and Ly10, respectively), DM-KG dosed intra-peritoneally significantly inhibited tumor growth in comparison to vehicle treated mice ($p<0.01$, n=16) (Figure 1B). To determine how DM-KG may induce growth suppression/apoptosis in mature B cell tumors, we first showed that in DLBCL cell lines α-KG inhibited the activity of ATP synthase, a key enzyme in the mitochondrial electron transport chain that generates most of the cellular ATP. Accordingly, short exposure (8h) to DM-KG suppressed ATP levels in all 14 DLBCL cell lines examined (mean=21%, range 3% to 50%). Next, we examined how the fuel stress generated by the α-KG-mediated ATP synthase inhibition influenced energy-saving cellular signals. We found that in cell lines and primary tumors, DM-KG consistently activated the kinase AMPK, with consequent marked inhibition of mTORC1. Importantly, these signals were also engaged in normal B cells, but they did not result in growth inhibition or apoptosis, thus highlighting the unique sensitivity of cancer cells to the modulation of energy metabolism.



α-KG inhibits the growth of DLBCL in vitro and in vivo (A and B) but it does not affect the viability of normal B cells from multiple donors (C)

Figure 1.

Summary/Conclusions: We showed that α-KG induces growth suppression and apoptosis in mature B cell tumors, *in vitro* and *in vivo*. We demonstrated that proximally α-KG exerts its tumor suppressive effects by inhibiting ATP synthase activity and ATP generation. This energy stress activates AMPK and suppresses mTORC1 resulting in growth inhibition and apoptosis in malignant cells, but not in their normal counterparts. These data highlight a metabolic cancer dependency and vulnerability that can be exploited therapeutically.

S127

DELETION OF THE F-BOX PROTEIN NIPA (NUCLEAR INTERACTION PARTNER OF ALK) IMPAIRS NPM-ALK DRIVEN TRANSFORMATION

L. J. Lippert[1,*], V. Shlyakhto[1], S. Kreutmair[1], C. Klingeberg[1], C. Albers[2], C. Miething[1,3], D. Justus[1,3], A. L. Illert[1,3]

für Translationale Krebsforschung (DKTK) und Deutsches Krebsforschungszentrum (DKFZ), Heidelberg, Germany

Background: ALCL is a high grade lymphoma characterized by anaplastic morphology, expression of CD30 (Ki-1) and T- or null cell phenotype. In 60% of systemic ALCL, the translocation t(2;5)(p23;q35) leads to expression of the oncogenic tyrosine kinase NPM-ALK. NIPA (Nuclear Interaction Partner of ALK) is an F-Box-Protein contributing to the timing of mitotic entry by defining an oscillating ubiquitin E3 ligase. NIPA deficient mice are viable but sterile due to impaired DNA double strand break repair. Co-expressed with NPM-ALK, NIPA is constitutively phosphorylated. However, the role of NIPA in NPM-ALK induced lymphomagenesis and the functional impact of this interaction remain unknown.
Aims: In this study, we aim to investigate the effect of *Nipa* deficiency on NPM-ALK driven cell proliferation and transformation in order to characterize the function of the protein in ALCL-induced lymphomagenesis.
Methods: Primary *Nipa*$^{-/-}$ MEFs infected with NPM-ALK were plated in softagar assays to evaluate their transformation ability. Moreover, NIPA was downregulated through targeted genetic approaches in Karpas299 and NPM-ALK infected Ba/F3 cells, which were analyzed regarding proliferation, signaling, and apoptosis. To assess the impact of *Nipa* deletion *in vivo*, we used a retroviral bone marrow transplantation model resembling human ALCL. Based on a Cre/loxP system under the LCK-Promotor, NPM-ALK expression and *Nipa*-deletion are restricted to early T cells. In wildtype background, mice die of systemic Thy1.2^{+}lymphoma with a latency of 4-6 months, developing neoplastic T-cell infiltration of bone marrow and lymphatic organs. Lymphomas were analyzed regarding immunphenotype and clinical presentation.
Results: Primary *Nipa*$^{-/-}$MEFs plated in softagar showed significantly reduced colony formation potential upon NPM-ALK expression (38 *vs* 79 CFUs; p<0.001). These results were substantiated in human and murine cell lines, where significantly reduced proliferation ability was observed in NIPA downregulating NPM-ALK expressing Ba/F3 cells (74% of ctrl; p<0.001) as well as in Karpas299 cells infected with NIPA miR (66% of wt growth; p<0.01). Moreover, treatment with the ALK inhibitor TAE-684 gave evidence of possible synergistic effects of ALK inhibition and NIPA knockdown. Mice transplanted with Lck-Cre$^{TG/wtNipaflox/flox}$MSNAIE infected bone marrow cells showed significantly prolonged disease development and progression (mean survival 143d *vs* 121d in wt). Morphologically, mice presented with enlarged thymi, splenomegaly, lymphadenopathy, and bone marrow infiltration. Immunphenotyping showed a pure T-cell phenotype in *Nipa*$^{-/-}$ lymphomas, thus resembling wildtype. In a long-latency model of NPM-ALK expression in enriched HSCs, a significantly prolonged survival (110 *vs* 80 days; p<0.01) and reduction of spleen colonies (10 *vs* 28 colonies/spleen; p<0.001) in mice transplanted with Mig$^{NPM\text{-}ALKNipa-/-}$ bone marrow compared to control animals were observed, thereby suggesting a crucial role of NIPA in NPM-ALK driven lymphomagenesis. To investigate the precise mechanism undelaying these results, we performed cell cycle analyses as well as cell viability assays. Indeed, we were able to detect significant differences in the cell viability in *Nipa* deficient NPM-ALK expressing cells, whereas cell cycle distribution seems not to be altered in knockout cells.
Summary/Conclusions: Taken together, we were able to show that NIPA is crucial for cell proliferation and transformation upon NPM-ALK expression. Investigations of the NIPA knockout mouse in a clinical relevant ALCL model highlight the importance of the NIPA/NPM-ALK axis in lymphoma development. Further analyses may thus elucidate NIPA as a novel molecular target for therapeutic intervention.

Thalassemia

GENE THERAPY FOR BETA THALASSEMIA: INITIAL RESULTS FROM THE PHASE I/II TIGET-BTHAL TRIAL OF AUTOLOGOUS HEMATOPOIETIC STEM CELLS GENETICALLY MODIFIED WITH GLOBE LENTIVIRAL VECTOR

S. Marktel[1,*], M.P. Cicalese[2], F. Giglio[1], V. Calbi[2], M. Casiraghi[2], S. Scaramuzza[3], F. Ciotti[2], M.R. Lidonicci[3], C. Rossi[3], N. Masera[4], E. D'Angelo[5], N. Mirra[5], R. Origa[6], G. Mandelli[3], R. Milani[7], S. Gattillo[7], M. Coppola[7], G. Viarengo[8], L. Santoleri[7], A. Calabria[3], E. Montini[3], G. Graziadei[9], L. Naldini[3], M. D. Cappellini[9], F. Ciceri[1], A. Aiuti[2], G. Ferrari[3]
[1]Haematology and BMT Unit, [2]Pediatric Immunohematology, [3]San Raffaele Telethon Institute for Gene Therapy, San Raffaele Scientific Institute, Milano, [4]Pediatric Department , San Gerardo Hospital , Monza, [5]Pediatric Clinic/DH, Fondazione IRCCS Ca' Granda, Milano, [6]Department of Biomedical Science and Biotechnology, University of Cagliari, Cagliari, [7]Blood Transfusion Service, San Raffaele Scientific Institute, Milano, [8]Immunohematology and Transfusion Medicine Service, Fondazione IRCCS Policlinico S. Matteo, Pavia, [9]Rare Disease Center, Fondazione IRCCS Ca' Granda, Milano, Italy

Background: Gene therapy for transfusion dependent beta-thalassemia, as an alternative cure to allogeneic HSCT, is based on the autologous transplantation of hematopoietic stem cells (HSCs) engineered by lentiviral vectors expressing a transcriptionally regulated human beta-globin gene.
Aims: Our contribution to this field was devoted to the clinical development of a gene therapy protocol based on high-titer vector GLOBE, use of lenograstim and plerixafor as source of HSCs and a conditioning regimen based on myeloablative treosulfan and thiotepa favoring efficient engraftment of corrected cells with reduced toxicity (TIGET-BTHAL; EudraCT number 2014-004860-39).
Methods: On the basis of extensive efficacy and safety preclinical studies the clinical trial TIGET-BTHAL was approved and started in 2015 at Scientific Institute San Raffaele, Milan, Italy. The clinical study foresees treatment of 10 patients: 3 adults followed by 7 minors, with a staggered enrolment strategy based on evaluation of safety and preliminary efficacy in adult patients by an independent data safety monitoring board before inclusion of pediatric subjects. The chosen route of administration of gene modified HSCs is intraosseous in the posterior-superior iliac crests, bilaterally, with the aim of enhancing engraftment and minimizing first-pass intravenous filter.
Results: As of February 2017, seven patients (3 adults and 4 pediatric patients) with different genotypes (β^0/β^0, $\beta^+/\beta^+$and β^0/β^+) have been treated with GLOBE-transduced CD34^{+}cells at a dose of $16x10^6$-$19.5x10^6$ cells/kg and a vector copy number (VCN)/cell ranging from 0.7 to 1.5. The procedure was well tolerated by all patients, with no product-related adverse events. Multilineage engraftment of gene-marked cells was observed in all tested peripheral blood and bone marrow samples. Polyclonal vector integrations profiles have been detected in the first 3 patients tested.
Summary/Conclusions: So far, the clinical outcome indicates reduction in transfusion requirement in adult patients and greater clinical benefit in younger patients. Follow up analysis are ongoing and updated clinical outcome will be presented.

S129

LUSPATERCEPT INCREASES HEMOGLOBIN AND DECREASES TRANSFUSION BURDEN IN ADULTS WITH B-THALASSEMIA

A. Piga[1,*], I. Tartaglione[2], R. Gamberini[3], E. Voskaridou[4], A. Melpignano[5], P. Ricchi[6], V. Caruso[7], A. Pietrangelo[8], X. Zhang[9], D. Wilson[9], A. Leneus[9], A. Laadem[10], M. L. Sherman[9], K. M. Attie[9], P. G. Linde[9]

Perrino", Brindisi, [6]AORN "A. Cardarelli", Naples, [7]ARNAS Garibaldi, Catania, [8]CEMEF, Medicina 2, Modena, Italy, [9]Acceleron Pharma Inc, Cambridge, [10]Celgene Corporation, Summit, United States

Background: Luspatercept (ACE-536), a fusion protein containing a modified activin receptor type IIB, is being developed for the treatment of β-thalassemia. Luspatercept binds to select TGF-β superfamily ligands (such as GDF11) reducing aberrant Smad2/3 signaling and promoting late-stage erythroid differentiation and increased hemoglobin (Hgb). Luspatercept corrected the effects of ineffective erythropoiesis in a mouse model of thalassemia (Suragani R, Blood, 2014) and increased Hgb and was well tolerated in a phase 1 study in healthy volunteers (Attie K, Am J Hematol, 2014).
Aims: This ongoing, phase 2, multicenter, open-label study followed by a long-term extension (ext) study evaluates the effects of luspatercept in patients (pts) with either transfusion-dependent (TD) or non-transfusion dependent (NTD) β-thalassemia with key endpoints of erythroid response (including Hgb increase) and pt-reported quality-of-life (QoL) in NTD patients, and reductions in RBC transfusion burden in TD patients.
Methods: Inclusion criteria: age ≥18 yr and either TD (≥4 RBC U/8 weeks prior

to first dose, confirmed over 6 months) or NTD (<4 RBC U/8 weeks prior to first dose with baseline Hgb <10 g/dL). Pts were treated every 3 weeks subcutaneously for up to 5 doses; 6 cohorts were treated at dose levels from 0.2-1.25 mg/kg. Pts in the expansion cohort and those who rolled over to the ext study were treated at ≥0.8 mg/kg with titration up to 1.25 mg/kg (base completed NCT01749540; ext ongoing NCT02268409).

Results: As of 02Sept2016, a total of 64 pts enrolled in the base study (31 TD, 33 NTD) and, of those, 51 enrolled in the ext study (24 TD, 27 NTD). Median (range) age (yr) was 38.5 (20-62); 67% had prior splenectomy. For TD pts, at baseline, median (range) transfusion burden was 8 U/12 weeks (4-18 U); mean (SD) liver iron concentration (LIC, mg/g dw) was 5.0 (5.3). For NTD pts, at baseline, median (range) Hgb (g/dL) 8.5 (6.5-9.8); mean (SD) LIC (mg/g dw) was 5.4 (3.8). In base and ext, respectively, 22/31 (71%) and 20/24 (83%) TD pts achieved ≥33% and 17/31 (55%) and 17/24 (71%) achieved ≥50% reduction in transfusion burden over any 12-week period compared to baseline. Median duration of ≥33% reduction was 6.3 months (treatment ongoing). In base and ext, respectively, in NTD pts treated with ≥0.6 mg/kg, 13/21 (62%) and 21/27 (78%) achieved ≥1.0 g/dL and 7/21 (33%) and 14/27 (52%) achieved ≥1.5 g/dL increases in mean Hgb over any 12-week period compared to baseline. Median duration of Hgb increase ≥1.0 g/dL over 12 weeks in responders was 13.5 months (treatment ongoing). Increases in mean Hgb over a 12-week period correlated with improvement in a pt-reported QoL questionnaire, FACIT-F. Luspatercept was generally well tolerated, with no related serious adverse events and few grade 3 related AEs: bone pain (n=3), asthenia (n=2), and headache (n=1). The most frequent related AEs (≥10%) were bone pain, myalgia, headache, musculoskeletal pain, arthralgia, and injection site pain.

Summary/Conclusions: Long-term luspatercept treatment in pts with β-thalassemia was generally safe and well tolerated. Efficacy was clinically relevant in both TD pts (decreased transfusion burden) and NTD pts (increased Hgb levels, improved QoL). A Phase 3, double-blind, placebo-controlled study of luspatercept in regularly transfused adults with β-thalassemia is ongoing (NCT02604433).

DENOSUMAB INCREASES BONE MINERAL DENSITY IN PATIENTS WITH THALASSEMIA MAJOR AND OSTEOPOROSIS: RESULTS OF A RANDOMIZED, PLACEBO-CONTROLLED, DOUBLE BLIND, PHASE 2B CLINICAL TRIAL

E. Voskaridou[1,*], A. Papaefstathiou[2], D. Christoulas[3], M. Dimopoulou[1], K. Repa[1], A. Papatheodorou[4], M. Peppa[2], E. Terpos[5]
[1]Thalassemia and Sickle Cell Disease Center, "Laiko" General Hospital, [2]Endocrine Unit, 2nd Department of Internal Medicine-Propaedeutic, Research Institute and Diabetes Center, National and Kapodistrian University of Athens, School of Medicine, Attikon University Hospital , [3]Department of Hematology, [4]Department of Biomedical Research, 251 General Air-Force Hospital, [5]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: Osteoporosis is a common complication of thalassemia major (TM) with a complex pathophysiology. We have previously shown that RANKL, the most potent osteoclast activator, is elevated in the serum of TM patients and correlates with reduced bone mineral density (BMD). Denosumab (DMB) is a human monoclonal antibody that targets and binds to RANKL and has been licensed for patients with different types of osteoporosis. However, there are no prospective data for the effects of DMB on TM-induced osteoporosis.

Aims: The primary objective of this study was to evaluate the results of DMB on lumbar spine (L1-L4) BMD in patients with TM and osteoporosis as compared to placebo at 12 months. Secondary endpoints included the evaluation of the effects of DMB on femoral neck (FN) and wrist (WR) BMD at 12 months, the safety profile of DMB as well as its effects on bone turnover.

Methods: This was a single-site, randomized, placebo-controlled, double blind phase 2b clinical trial. Main inclusion criteria included adult patients (>30 years of age) with TM and BMD T-score between -2.5 and - 4.0 in at least one of the examined sites (L1-L4, FN, WR). Main exclusion criteria included: impaired renal function (eGFR of ≤30 mL/min); elevated ALT and/or AST >2 fold the upper limit of normal (UNL), or elevated direct bilirubin >1.5xUNL; heart failure (NYHA above 2); administration of bisphosphonates within one year of study enrolment; presence of any other disorder that affects bone metabolism. Patients were assigned into two treatment groups: in group A, 60 mg DMB was administered sc, every 6 months for 12 months for a total of 2 doses (day 0 and day 180); in group B, placebo was administered sc, at the same time. All patients received calcium and vitamin D supplementation. Measurement of BMD with dual energy X-ray absorptiometry at three body sites (L1-L4, FN, WR) was performed during the screening period and at the end of the study.

Results: Sixty-three patients with TM and osteoporosis participated in the study (group A, n=31; group B, n=32). Patients of groups A and B showed no differences in BMD of all evaluated sites at baseline. Patients of group A (DMB arm) achieved an increase in both L1-L4 BMD (mean±SD: 0.811±0.105 g/cm2 *vs* 0.772±0.098, p<0.001) and FN BMD (0.653±0.121 g/cm2 *vs* 0.631±0.103, p=0.022), while there were no changes in WR BMD. Patients of group B (placebo arm) achieved a slight increase in their L1-L4 BMD (0.801±0.097 g/cm2 *vs* 0.775±0.080, p=0.004) and a significant decrease in their WR BMD (0.520±0.099 g/cm2 *vs* 0.549±0.098, p=0.008). The percentage increase of L1-L4 BMD was higher in DMB arm than in placebo arm (6.02±5.30% *vs* 3.11±5.46%, respectively; p=0.03), while the advantage of DMB regarding WR BMD was much higher compared to placebo (-0.22±5.40% *vs* -4.15±8.58%, respectively; p=0.02) as well as in FN BMD (p<0.001). No grade 3 or 4 toxicity was observed in this study.

Summary/Conclusions: This first analysis of our phase 2B study regarding the effects of DMB on BMD of different sites (the results of bone markers will be presented in the conference), suggests that DMB, given twice per year, increases the BMD of the L1-L4 more efficiently than placebo (in combination with vitamin D and calcium), after 12 months, in patients with TM and osteoporosis, with excellent safety profile. Furthermore, DMB increased the FN BMD, which was not increased in the placebo arm, while DMB has also a positive effect on WR BMD compared to placebo. These data support the use of DMB for the management of TM-induced osteoporosis.

S131

LONG-TERM HEALTH STATUS AFTER HSC TRANSPLANTATION FOR THALASSEMIA: THE FRENCH EXPERIENCE

Background: In clinical practice**,** allogeneic hematopoietic stem cell transplantation (HSCT) is the only treatment offering a definitive cure for patients with beta-thalassemia. Its outcome has improved over the last 3 decades with currently a disease free survival rate of 90% when transplant is performed in childhood from an HLA-identical sibling. Few data are available on long-term toxicity and frequency of chronic complications after transplant.

Aims: The purpose of this study was to evaluate the long-term health status after a successful allogeneic HSCT for beta-thalassemia major in a national cohort of patients.

Methods: This French retrospective study included patients who successfully received allogeneic HSCT between 1985 -2012 and were alive at least 2 years after HSCT. Study was based on data collected in the national registry of patients with beta-thalassemia and conducted in collaboration with the French society of HSCT (SFGM-Tc). Late effect data were recorded by physicians through reference or transplant center visits. Collected data included medical examination results, long-term treatments administered and laboratory tests (serum ferritin, Hb, liver enzymes, creatinine level and thyroid evaluation). Linear-mixed model was used to analyze data evolution over time (for height and weight SDS, SF, Hb values).

Results: A total of 134 patients had received allogeneic HSCT for beta-thalassemia in France from 1985 to 2012. 107/134 patients experienced successful HSCT (6 after a second transplant) and were alive 2 years after transplantation. Six were not analyzed (back to their country or lost of follow-up) and two died of chronic graft-*versus*-host disease. 99 patients were analyzed for long-term effects. Median age at HSCT was 5.9 years (8 month-26 years). The source was bone marrow in 85% of cases and a matched sibling donor was used in 90% of cases. Conditioning mostly consisted (85%) of busulfan and cyclophosphamide (oral busulfan in 52%). Median age at the last visit was 19 years. Chronic complications, similar to those observed in patients treated with transfusion and chelation therapy occurred after transplant in 12% of patients: 7 hypothyroidism, 2 heart failure, 5 diabetes. 2 patients had chronic respiratory failure related to transplant. The height SDS improved after HSCT if performed at a young age. Weight

SDS values increased with time, especially in females. Although gonadal dysfunction was observed in 60% of women aged at least 13 years at the last evaluation, 12/27 aged more than 20 years experimented at least one successful pregnancy. 93 patients had stopped their immunosuppressive treatment two years after HSCT. 37 were treated with iron chelation therapy and/or phlebotomies. At least half of patients are receiving a long-term hormonal treatment or antibiotic prophylaxis at the last visit. Decrease in serum ferritin values after transplant was significantly influenced by age at transplant and pre-transplant serum ferritin value. The median hemoglobin value was 12.5 g/dL (86-165) at a mean age of 18 years and Hb values were significantly influenced by age, the sex of the donor and the presence of donor thalassemia trait.
Summary/Conclusions: A comprehensive and regular long-term follow-up should be established for all patients receiving allogeneic HSCT for beta-thalassemia major. In this national cohort, endocrinological complications were frequent after transplant. Fertility can be partly preserved, but this result has to be reevaluated with the more recent use of intravenous busulfan.

S132

CD34+AND HUMAN INDUCED PLURIPOTENT STEM CELL DIFFERENTIATION TO TRANSFUSION READY RED BLOOD CELLS

M.-J. Claessen[1,2,*], E. Varga[1], M. Hansen[1], P. Burger[1], S. Heshusius[1], T. Wust[1], J. Eernstman[1], M. Thiel[1], E. Heideveld[1], E. Sellink[1], M. von Lindern[1], E. van den Akker[1]
[1]Hematopoiesis, Sanquin Research, [2]Hematology, AMC Amsterdam, Amsterdam, Netherlands

Background: Donor-derived red blood cells (RBC) are the most common form of cellular therapy. However the source of cells is dependent on donor availability with a potential risk of allo-immunization and blood borne diseases.
Aims: We aim to produce unlimited numbers of cultured RBC with a defined `universal donor´ phenotype for transfusion purposes.
Methods: To this end we prepare for a clinical test using autologous cultured RBC to test their *in vivo* stability. In parallel we develop methods for unlimited production of cultured RBC. An immortal source to produce *in vitro* cultured RBCs (cRBC), such as iPSCs would allow selection of `universal donor` RBC, or provide an autologous end product with the absence of immune reactions.
Results: The *in vitro* production of RBC has proven to be successful, however there are barriers to overcome prior to clinical application. e.g: xeno-free culturing methods, scale up cultures to obtain transfusion units (1-2*10^{12} erythrocytes), and for iPSC we need virus- and transgene-free reprogramming protocols. To solve the above mentioned issues a customized humanized GMP-grade medium (Cellquin) was generated in order to control erythroid culture parameters and to reduce culture costs. This medium allowed 1*10^{8} times erythroid expansion from PBMCs to pure adult EBL cultures within 25 days, comparable to non-GMP commercial media. To generate iPSC, a non-integrative polycistronic episomal vector containing (OCT4-SOX2-KLF4-cMYC-LIN28) was used to reprogram PBMC-expanded EBLs to iPSC, displaying pluripotency potential and normal karyotype. iPSCs were adapted to single cell passage allowing directed colony differentiation using a feeder-free monolayer approach. From day 6 of differentiation Cellquin was applied with lineage-specific growth factors, resulted iPSC differentiation to EBLs which was initiated by the appearance of hemogenic endothelium following hematopoietic specification. Our differentiation method resulted in ~150*10^{6} CD41- CD34-CD71+CD235+CD36+expanded EBLs from 1200iPSCs within 21 days (12 days of iPSC diff. +9 days of expansion). Further maturation of iPSC-EBLs yielded CD71+CD235+CD36- pure orthochromatic normoblasts expressing mainly gamma globin chains (fetal) and small amount of beta globins (adult) in agreement with literature. Currently we are testing enucleation potential of matured iPSC-EBLs.
Summary/Conclusions: Here we showed that our monolayer approach is simple, highly controlled and compatible with upscaling. Avoiding virus-, integrative reprogramming, feeders and with our GMP-grade media we maintained a cost effective system moving toward clinical application.

AML Biology I: Towards molecular therapies

S133

FUNCTIONAL PROTEOMICS IDENTIFIES SETD2 AS A CRITICAL EFFECTOR OF MLL FUSION PROTEINS TO SAFEGUARD GENOMIC INTEGRITY

A. Skucha[1,*], J. Ebner[2], J. Schmöllerl[2], A. César Razquin[1], T. Eder[2], A. Stukalov[1], S. Vittori[1], M. Muhar[3], M. Roth[3], B. Györffy[4], P. Valent[5], K. Bennett[1], J. Zuber[3], G. Superti-Furga[1,6], F. Grebien[2]
[1]CeMM - Research Center for Molecular Medicine of the Austrian Academy of Sciences, [2]Ludwig Boltzmann Institute for Cancer Research, [3]IMP - Research Institute of Molecular Pathology, Vienna, Austria, [4]MTA TTK Lendület Cancer Biomarker Research Group, Budapest, Hungary, [5]Department of Internal Medicine , Division of Hematology & Hemostaseology, Medical University of Vienna, [6]Center for Physiology and Pharmacology, Medical University of Vienna, Vienna, Austria

Background: Acute Myeloid Leukemia (AML) frequently harbors chromosomal rearrangements involving the Mixed Lineage Leukemia *(MLL)* gene. More than 65 different MLL fusion genes exist and many of them have been described to act as strong cancer drivers. While critical effectors of several distinct MLL fusion proteins (MLL-FPs) were identified, it is not clear if transforming mechanisms are conserved across the entire family of MLL fusions.
Aims: We hypothesized that common oncogenic mechanisms are encoded in stable physical and genetic MLL-fusion-specific interaction networks. Thus, we aimed to identify common critical effectors of different MLL fusion proteins that are presumed to employ different mechanisms of oncogenic transformation.
Methods: Protein complexes of 7 molecularly distinct, affinity-tagged MLL-FPs (MLL-AF4, MLL-AF9, MLL-ENL, MLL-CBP, MLL-EEN, MLL-GAS7 and MLL-AF1p) were purified from stable cell lines allowing for inducible, single-copy transgene expression and characterized by mass spectrometry. Data analysis identified a comprehensive protein-protein interaction network, which was functionally interrogated by a subtractive shRNA screening approach. Validation experiments included detailed RNAi- and CRISPR/Cas9-mediated loss of function experiments in cell lines and primary cells *in vitro* and *in vivo*, using readouts for changes in proliferation, differentiation, apoptosis and DNA damage.
Results: Characterization of the protein complexes nucleated by 7 MLL fusion proteins by affinity purification coupled to mass spectrometry (AP-MS) revealed a densely interconnected protein-protein interaction network of 963 proteins, comprising previously known MLL-interacting protein complexes (such as PRC2 or SWI/SNF), as well as a high number of new interaction partners of MLL. 128 proteins were found to interact with ≥5 of all 7 MLL-fusions. This subset of conserved MLL-interaction partners was highly enriched for proteins with function in chromatin metabolism and transcriptional control. Systematic functional investigation of the conserved MLL-fusion interactome using subtractive shRNA screens identified the methyltransferase SETD2 as a critical effector of MLL fusion proteins. Both RNAi-based suppression and CRISPR/Cas9-mediated mutagenesis of SETD2 induced myeloid differentiation and apoptosis in human and mouse MLL-rearranged cell lines, while having only modest effects on the proliferation of MLL-wild-type leukemia cells. Depletion of *Setd2* in MLL-fusion-transformed mouse fetal liver cells resulted in loss of serial re-plating capacity *in vitro* and prolonged disease onset *in vivo*. Furthermore, knockdown of *SETD2* caused a proliferative disadvantage in primary cells from AML patients with different MLL-rearrangements without affecting MLL-wild-type AML cells. We found that SETD2 was essential for efficient repair of DNA breaks, as SETD2-deficient leukemia cells showed increased levels of DNA damage and activation of p53, leading to the accumulation of mutations.
Summary/Conclusions: In summary, our data highlight the functional relevance of combined proteomic-genomic cellular screening to identify critical effectors of MLL-FPs. In addition, our study identifies a novel role for SETD2 in the maintenance of genomic integrity during initiation and progression of MLL-rearranged AML and establishes SETD2 as a therapeutic target in leukemia with low genomic complexity.

S134

CEBPA-MUTANT ACUTE MYELOID LEUKEMIA IS SENSITIVE TO SMALL-MOLECULE-MEDIATED INHIBITION OF THE MENIN-MLL INTERACTION

L. Schmidt[1,*], E. Heyes[1], T. Eder[1], J. Grembecka[2], F. Grebien[1]
[1]Ludwig Boltzmann Institute for Cancer Research, Vienna, Austria, [2]Department of Pathology, University of Michigan, Ann Arbor, United States

Background: The *CEBPA* gene - encoding for the transcription factor C/EBPα - is mutated in 9% of patients with acute myeloid leukemia (AML). *CEBPA* N-terminal mutations lead to selective loss of full length C/EBPα p42 expression without affecting translation of the shorter p30 isoform. As a balanced ratio of C/EBPα isoforms is crucial for hematopoietic homeostasis, depletion of p42 leads to increased cell growth and blocks myeloid differentiation, resulting in the development of AML. We have recently shown that the p30 variant of

C/EBPα can act as a gain-of-function allele with distinct molecular properties. However, the mechanistic basis of C/EBPα p30-induced leukemogenesis is incompletely understood.
Aims: We hypothesized that the interaction between the oncogenic C/EBPα p30 isoform and the MLL/SET histone methyltransferase complex is required for p30-dependent epigenetic and transcriptomic changes that contribute to leukemogenesis. Therefore, we aimed to investigate the sensitivity of *CEBPA*-mutant AML to perturbation of MLL/SET function.
Methods: We used CRISPR/Cas9-mediated mutagenesis to interfere with the MLL/SET complex in myeloid progenitor cells from a *Cebpa*$^{p30/p30}$ AML mouse model. Cellular competition assays were used to assess changes in proliferative capacity of mutant cells. Further, MLL activity was inhibited by the use of small molecules that block the Menin-MLL interaction. In both cases, proliferation, myeloid differentiation and apoptosis were used as readouts. Global changes in gene expression were measured by RNA-seq.
Results: We initially confirmed, via ChIP, that C/EBPα and MLL co-localize on the promoters of p30 target genes, indicating functional cooperativity in gene regulation. To investigate the importance of different, annotated functional domains within the MLL protein in the context of C/EBPα p30 expression, we introduced targeted mutations across the *Mll* gene in *Cebpa*$^{p30/p30}$ cells using the CRISPR/Cas9 system. This analysis revealed a strong dependence of *Cebpa*$^{p30/p30}$ cells on the expression of an intact MLL protein. Surprisingly, loss of the enzymatic activity of *Mll* by mutational targeting of the SET domain did not significantly affect cell survival. In contrast, cells were particularly sensitive to mutagenesis of the Menin-binding motif in MLL. *Mll* targeting strongly induced myeloid differentiation in *Cebpa*$^{p30/p30}$ cells as measured by increased levels of myeloid surface markers. To investigate functional consequences upon pharmacological perturbation of the MLL/SET complex, we used MI-463, a potent small-molecule inhibitor of the Menin-MLL interaction. Inhibitor treatment led to a time- and dose-dependent impairment of proliferation, induction of cell cycle arrest and increased apoptosis in *Cebpa*$^{p30/p30}$ cells. RNA-seq analysis showed that inhibitor treatment induced the expression of genes associated with myeloid differentiation, which could be confirmed by flow cytometry. Importantly, expression of C/EBPα p30 was associated with hypersensitivity to Menin-MLL inhibition, as *Cebpa*$^{p30/p30}$ cells were 2-6 fold more sensitive than other leukemia cell lines of mouse and human origin.
Summary/Conclusions: We show that *CEBPA*-mutated AML is highly sensitive to perturbation of the MLL/SET complex, either via genetic ablation of MLL or through pharmacological inhibition of the Menin-MLL interaction. Our data indicate that leukemic mutations of C/EBPα selectively cooperate with the SET/MLL complex to regulate gene expression. These findings expand our understanding of and may inform new therapeutic strategies for N-terminal *CEBPA* mutated AML.

S135

INHIBITION OF THE MYELOID MASTER REGULATOR PU.1 AS A THERAPEUTIC STRATEGY IN ACUTE MYELOID LEUKEMIA

I. Antony-Debre[1,2,*], J. Leite[1], A. Paul[3], K. Mitchell[1], H. M. Kim[3], K. Huang[3], A. Kumar[3], A.A. Farahat[3], B. Bartholdy[1], S.-R. Narayanagari[1], L.A. Carvajal[1], J. Chen[1], A. Ambesi-Impiombato[4], A.A. Ferrando[4], I. Mantzaris[1], E. Gavathiotis[1], A. Verma[1], B. Will[1], D. W. Boykin[3], W. D. Wilson[3], G. M. K. Poon[3], U. Steidl[1]
[1]Albert Einstein Cancer Center, Albert Einstein College of Medicine, New York, United States, [2]Inserm U1170, Gustave Roussy, Villejuif, France, [3]Department of Chemistry, Georgia State University, Atlanta, [4]Institute for Cancer Genetics, Columbia University, New York, United States

Background: Functionally critical decreases in PU.1 levels or activity are present across various different genetic and epigenetic subtypes of AML, and overall represent more than 50% of AML cases (Sive *et al.* Leukemia. 2016). However, approaches for the specific therapeutic targeting of these patients are thus far lacking.
Aims: Retroviral restoration of PU.1 expression has previously been explored but is difficult to achieve pharmacologically. Here, we tested the inverse strategy. As complete loss of PU.1 leads to stem cell failure, we hypothesized that AML cells harboring already low levels of PU.1 may be more vulnerable to further PU.1 inhibition.
Methods: We used two alternative approaches: RNA interference and newly developed small molecule PU.1 inhibitors.
Results: We found that inhibition of PU.1 with different shRNAs led to a significant decrease in proliferation and clonogenicity, and increased apoptosis of mouse and human leukemic cell lines with low PU.1 levels, as well as the majority of primary human AML cells tested. The pharmacologic targeting of transcription factor-DNA major groove interactions is challenging. However, specific PU.1 binding to chromatin critically depends on additional minor groove contacts upstream of the core ETS binding motif, which determine selectivity for PU.1. We used an integrated screening strategy utilizing biosensor surface plasmon resonance, DNA footprinting, and cell-based dual-color PU.1 reporter assays to develop novel small molecules of the heterocyclic diamidine family as first-in-class PU.1 inhibitors. Targeted occupancy by our compounds in the minor groove induces perturbations in DNA conformation that are transmitted to the PU.1 site in the major groove and thus inhibit PU.1 binding via an allosteric mechanism. Functionally, treatment with 3 different compounds decreased cell growth and colony forming capacity, increased apoptosis, and disrupted serial replating capacity of PU.1^{low} AML cell lines, and a majority of primary AML cell samples. ChIP and expression analysis showed that the compounds disrupt PU.1-promoter interaction and lead to downregulation of canonical PU.1 transcriptional targets in AML cells, confirming on-target activity. Genome-wide analysis showed highly significant enrichment of known transcriptional targets of PU.1, and selectivity over other ETS family members. Comparison with published transcriptomic and PU.1 ChIP-seq data sets, as well as ARACNe analysis of the PU.1 regulon in primary AML cells, demonstrated that the inhibitors antagonized PU.1-regulated pathways at a genome-wide level. Treatment of normal HSPC in colony forming assays led to decreased production of mature granulo-monocytic cells, consistent with PU.1's known role in this lineage. However, this effect was reversible upon drug removal, and serial replating capacity was not affected suggesting no significant effects on normal HSPC. Lastly, *in vivo* treatment with PU.1 inhibitors in mouse and human AML (xeno)transplantation models significantly decreased tumor burden and increased survival.
Summary/Conclusions: Our study describes for the first time a strategy inhibiting PU.1 in AML, establishing proof-of-concept for this approach. Furthermore, we report the development of first-in-class PU.1 inhibitors which interfere with PU.1-DNA interaction through an allosteric, minor groove-mediated mechanism. Our work shows that it is feasible to pharmacologically target PU.1, and raises intriguing possibilities for the potential targeting of other transcription factors through minor groove-directed approaches.

METABOLIC ADAPTATIONS TO TARGETED THERAPY IN FLT3 MUTATED ACUTE MYELOID LEUKAEMIA

P. Gallipoli[1,*], A. S. Costa[2], K. Tzelepis[3], G. Giotopoulos[1], S. Vohra[1], G. Vassiliou[1], C. Frezza[2], B. Huntly[1]
[1]Haematology, [2]MRC Cancer Unit, [3]Wellcome Trust/Sanger Institute, UNIVERSITY OF CAMBRIDGE, Cambridge, United Kingdom

Background: FLT3 tyrosine kinase (TK) activating mutations (FLT-3^{mut}) are amongst the most frequent in AML and are associated with a poor outcome. FLT-3^{mut}promote constitutive activation of survival/proliferation pathways and have also been shown to lead to changes in cellular metabolism, such as increased glycolysis. The FLT3 TK represents a valid therapeutic target and several FLT3 TK inhibitors (TKI) have been developed. However despite showing activity in the preclinical setting, FLT3 TKI have displayed limited efficacy in clinical trials. Resistance mechanisms to FLT3 TKI include receptor mutations and cell intrinsic adaptive mechanisms. Amongst the latter, metabolic adaptations might play a significant role although the exact mechanisms are still ill-defined.
Aims: We hypothesised that metabolic adaptations facilitate FLT3 TKI resistance and aimed to identify early metabolic changes in FLT-3^{mut} AML, following TKI treatment, in an attempt to unveil novel therapeutic vulnerabilities.
Methods: Liquid chromatography coupled to mass spectrometry (LC/MS), using stable isotope-based carbon flux tracing, and oxygen consumption rate/extracellular acidification rate as measured by an extracellular flux analyser (Seahorse, Agilent Technologies) were used to assess metabolic changes in FLT3^{mut} cells after FLT3 TKI treatment. Gene expression changes were measured in the same conditions by RNA sequencing. Changes in viability and reactive oxygen species (ROS) in various culture conditions were measured by FACS. Gene silencing was performed using CRISPR-Cas9 gene editing and inducible short hairpin RNA interference.
Results: Analysis of published gene expression datasets demonstrated that glycolytic, citric acid cycle (CAC), and oxidative phosphorylation genes are upregulated in FLT-3^{mut} compared to FLT3 wild-type (FLT3^{wt}) patient samples at diagnosis. We then confirmed that both human and murine FLT-3^{mut} cells display increased glycolytic and respiratory capacity compared to FLT-3^{wt} cells. Upon treatment with the highly selective FLT-3 TKI AC220 (quizartinib), currently used in a number of clinical trials, these metabolic phenotypes were partially reversed. However, whilst glucose uptake was reduced upon FLT3 TK inhibition, glutamine uptake was not affected. Metabolic flux analysis using [U-^{13}C]glutamine demonstrated that glutamine, while providing carbons for the CAC, was primarily used to support production of the major intracellular antioxidant glutathione upon AC220 treatment. This antioxidant function is necessary because, as expected, FLT-3^{mut} cells displayed a large increase in ROS levels following TKI treatment when grown in the absence of glutamine and these changes correlated with a significant reduction in viability in the same conditions. Glutamine dependency of FLT3^{mut} cells upon FLT3 TKI treatment was independently validated via a CRISPR-Cas9 drop-out genome-wide screen as glutaminase (GLS), the first enzyme in glutamine catabolism, and several CAC enzymes were shown to be synthetically lethal with AC220. We went on to show that the combination of AC220 with a specific clinical grade GLS inhibitor (CB-839) or GLS gene silencing resulted in a significant reduction in viability and increase in ROS levels which could be rescued by supplementation of the media with the antioxidant N-acetylcysteine or a cell-permeable form of the CAC intermediate α-ketoglutarate.

Summary/Conclusions: Our data suggest that upon AC220 treatment, glutamine metabolism becomes a critical metabolic dependency in FLT3^{mut} AML. Glutamine metabolism is mostly channelled towards glutathione production, while also supporting the CAC and both these fates contribute to its protective effects following FLT3 TK inhibition by respectively counteracting oxidative damage and sustaining macromolecule biosynthesis and cellular energetics. These data predict that a combined inhibition of glutamine metabolism and FLT3 TK activity may improve the eradication of FLT3^{mut} AML cells.

STEP-WISE REPROGRAMMING OF ENDOTHELIAL CELLS INTO IMMUNE-COMPETENT HEMATOPOIETIC STEM CELLS

J. G. Barcia Duran[1,*], R. Lis[2], C. C. Karrasch[3], B. Kunar[1], S. Rafii[3]
[1]Physiology, Biophysics and Systems Biology, Weill Cornell Graduate School of Medical Sciences, [2]Medicine, Weill Cornell Medicine, [3]Medicine, Weil Cornell Medicine, New York, United States

Background: The molecular pathways and microenvironmental cues that choreograph the conversion of endothelial cells (ECs) into long-term repopulating hematopoietic stem cells (HSCs) remain poorly defined. This is due to lack of models that recreate the ephemeral transition of an endothelial cell to a hemogenic state to the emergence of HSCs.
Aims: To reprogram adult mouse ECs into long-term repopulating HSCs that give rise to all hematopoietic lineages, including functional T cells *in vivo*.
To provide a platform to deconvolute the process by which endothelial-to-hematopoietic transition is possible.
Methods: Here, we have developed a modular *in vitro* model in which—by precise, conditional expression of transcription factors: *FosB*, *Gfi1*, *Runx1*, and *Spi1* (FGRS), and reintroduction of a proper inductive niche—adult mouse ECs were reprogrammed into HSCs (rEC-HSCs) with multi-lineage engraftment potential (rEC-MPPs). Adult, non-lymphatic ECs isolated from various organs of Runx1-IRES-GFP reporter mice were transduced with *FGRS* and co-cultured in direct contact with vascular niche.
Results: Within 14 days, ECs initiated a hematopoietic program, turning on the endogenous expression of Runx1 and transitioning into hematopoietic cells. Expansion of these cells for another 14 days resulted in generation of rEC-HSCs and rEC-MPPs. Transplantation of rEC-HSCs and rEC-MPPs (CD45.2^{+}) into lethally irradiated mice (CD45.1^{+}) reconstituted both short-term (rEC-MPPs) and long-term hematopoiesis, with secondary engraftment potential (rEC-HSCs). rEC-HSCs gave rise to both functional myeloid and lymphoid cells with full complement of polarized T cell subsets. rEC-HSC-derived T cells undergo T-cell receptor (TCR) rearrangement and restore adaptive immune function in Rag1$^{-/-}$ mice.
Summary/Conclusions: This multi-phasic, step-wise approach provided an interrogable model to decipher pathways involved in EC transition into hematopoietic cells. This will provide cues to devise strategies to convert autologous ECs into large numbers of HSCs for genetic modification and subsequent treatment of both genetic and acquired hematological disorders.

S138

MARROW MESENCHYMAL STEM CELLS RESCUE BONE MARROW ENDOTHELIAL CELLS SUFFERING CHEMOTHERAPY STRESS BY TRANSFERRING MITOCHONDRIA THROUGH NANOTUBES

Y. Feng[1,*], R. Zhu [2], W. Lu[3], J. Shen[4], J. WU[5], J. Zhang[3], Y. Y. Zhang[6], K. Liu[3]
[1]Peking University People's hospital, Institute of Hematology, Beijing, [2]Centre of Excellence in Tissue Engineering, Peking Union Medical College hospital, [3]Peking University People's hospital, Institute of Hematology, [4] The Third Hospital of Peking University , Cardiovascular Institute, Beijing, [5] The Third Hospital of Peking University , Cardiovascular Institute, Beijing, [6]The Third Hospital of Peking University , Cardiovascular Institute, Beijing, China

Background: The tunneling nanotube (TNT) is a newly discovered,long and thin tubular structure between cells and can facilitate the intercellular exchange of diverse cellular signals and components ranging from electrical signalling to organelles .
Recent reports show that mesenchymal stem cells (MSC) rescue injured target cell and promote target cell recovery from a variety of stress including oxidative tress. ultraviolet radiation, ischemia/reperfusion (SI/R)etal .However, it is still unclear if bone marrow mesenchymal stem cells (BMMSC) can also form TNT to communicate and rescue injured bone marrow -derived endothelial cells (BMdEC)and promote it recovery from chemotherapy stress . In our study, we set out to test the hypothesis that BMMSC can rescure suffering endothelial cells by transferring mitochondria to endothelial cells through nanotubes.
Aims: To investigate the novel intercellular communication TNT between BMMSC and BMdECs or HUVEC, illuminating its constituent and investigating the significance of transport of mitochondrial through TNT between BMMSC and BMdECs or HUVEC suffering from chemotherapy stress of cytosine arabinoside.
Methods: We established two direct co-culture system for human primary bone marrow mesenchymal stem cells (BMMSCs) and bone marrow-derived endothelial cells (BMdECs) or Human umbilical cord vein endothelial cells (HUVECs) respectively.
Results: Firstly, We observed the TNTs formed between BMMSCs and endothelial cells including HUVECs and BMdECs. We identified the TNT structure between BMMSCs and HUVECs or BMdECs are composed with F-actin, microtubule in addition to membrane. Live cell imaging showed the two xenogeneic cells form TNTs by retaining a thin thread of membrane upon dislodge-

ment .Besides,we observed that TNT was more likely to occur between healthy bone marrow mesenchymal stem cell and endothelial cells after cytarabine (Ara-C) treatment. Single-cell analysis showed that stressed endothelial cells and cell lines in the early stages of apoptosis caused by cytarabine (Ara-C) treatment form TNT to interact with untreated BMMSCs and then mesenchymal stem cells transport mitochondria to injured endothelial cell or cell line.Notably,the rescue effect was inhibited when the formation of TNTs were impaired by incubating with an F-actin-depolymerizing drug and tubline -depolymerizing drug, indicated that these TNTs transferring mitochondria have a distinct cytoskeletal composition which composed with F-actin and microtubule. Our results also suggest that the delivery of functional mitochondria from untreated BMMNCs to HUVECs via TNTs can mediate the recovery of injured HUVECs from the apoptosis, contribute to proliferation and remodel the formation of capillary-like structures in Matrigel®-coated plates of HUVECs suffer from chemotherapy stress of Ara-C.

Summary/Conclusions: BMMSCs can transfer mitochondria via TNTs formed between endothelial cells and rescued endothelial cellssuffering chemotherapy stress,which can alleviate apoptosis of stressed endothelial cells, relieve its proliferation inhibition and alter its formation of capillary-like structures.Our study offers the clues to help know about cell-cell communication of niche components in the HSC niche in bone marrow.

S139

SHORT-TERM FEEDING OF A HIGH-FAT DIET DISTURBS LIPID RAFT/TGF-BETA SIGNALING-MEDIATED QUIESCENCE OF HEMATOPOIETIC STEM CELLS IN C57BL/6J MOUSE BONE MARROW

F. Hermetet[1,2,*], J.-P. Pais de Barros[2,3], L. Delva[1,2], R. Quéré[1,2]
[1]Signaling and Physiology in Hematological Research, UMR1231 Inserm / Université Bourgogne Franche-Comté / AgroSup, [2]LabEx LipSTIC, [3]Lipidomic Analytical Platform, UMR1231 Inserm / Université Bourgogne Franche-Comté / AgroSup, Dijon, France

Background: Some studies show that a high-fat diet (HFD) induces major perturbations in murine hematopoietic stem cells (HSC) and hematopoietic system homeostasis. However, it is currently difficult to say whether these alterations are related to direct effects such as changes in lipid metabolism in HSC or indirect "side effects" on HSC, such as pathophysiology related to obesity or inflammation observed after an extended diet over several months or a diet very rich in fat (>60 kJ% of fat). For example, HFD-induced obesity significantly alters hematopoiesis in bone marrow (BM), with a decreased proliferation of HSC, a general suppression of progenitors, an enhancement of lymphopoiesis, and an activation of myeloid cell production from BM progenitors. Inflammation also affects HSC homeostasis, as Interferon alpha is well-known to activate dormant HSC *in vivo*.

Aims: Our strategy is to characterize the impact of a short-term HFD on HSC and hematopoiesis in non-obese C57BL/6J mice.

Methods: In a prospective study, C57BL/6J mice were fed a control diet (4 kJ% of fat) or HFD (42 kJ% of fat), over a short period of 4 weeks, to investigate the direct-impact of such a diet on hematopoiesis.

Results: While fat intake leaded to an increase in plasma cholesterol levels, mice did not develop obesity, and no inflammatory monocytes and no modulation of pro-/anti-inflammatory cytokine levels were detected in blood and BM, respectively. No significant impact was observed on the total number of cells in blood and BM. However, we noted an increase in the number of progenitors and a loss of more than 50% of the most primitive HSC (SLAM). We validated this loss via transplantation of BM isolated from HFD-fed mice (Ly.1) in competition with control BM (Ly.2), in lethally irradiated recipient mice which only reconstitute 20% of the recipient hematopoiesis from HFD HSC. To further investigate lipid metabolism in HSC, we quantified the major lipid constituents in control and HFD HSC. Among altered lipids, cholesterol was the most affected in HFD HSC. These changes might alter the structure of the HSC plasma membrane such as lipid rafts (LR), which are important for signal transduction in hematopoiesis, driving the retention/dormancy of HSC in BM. To determine if fat intake may affect LR quantity in hematopoietic cell membrane, we stained Lineage-negative (Lin^-) cells with the cholera toxin subunit B (CTB) and analyzed the distribution of different populations of hematopoietic cells, expressing either high (CTB^{hi}) or low (CTB^{lo}) levels of LR. Fat intake disrupts CTB^{hi} cells in the Lin^- $Sca\text{-}1^+$ $c\text{-}Kit^+$(LSK) and LSK-$CD34^-$ compartments, while no variation was detectable among progenitors (Lin^- $c\text{-}Kit^+$and Lin^-). Importantly, we discovered that CTB^{hi} cells were enriched with SLAM HSC (46%, *versus* 2% for the CTB^{lo}). While we found ~50% of CTB^{hi} cells among LSK-$CD34^-$ HSC in control diet-fed mice, a HFD has led to a loss of the CTB^{hi} population. Using the proliferation marker Ki67, we observed a decrease in the proportion of LSK-$CD34^-$ primitive HSC in G0, meaning that HSC quiescence state was affected by a HFD. Transforming growth factor (TGF)-β signaling has long been known to be involved in modulating HSC quiescence, partly by preventing HSC re-entry into the cell cycle. As a HFD induced a loss of LR on HSC, we looked at the localization of TGF-β receptor 1 (TR1) on the LSK-$CD34^-$cell surface. While TR1 strongly colocalized with LR in macrodomains on HSC, we observed that LR were more organized in microdomains and the delocalization of TR1 among LR was furthermore detected when mice were fed a HFD. Moreover, reduced phospho-Smad2/3 indicated lower activation of the TGF-β pathway in HSC purified from HFD-fed mice. Finally, injection of recombinant TGF-β1 led to the rescue of the 4 week HFD-dependent SLAM HSC depletion, which clearly highlights that a HFD affects TGF-β signaling on HSC.

Summary/Conclusions: In conclusion, HFD markedly and rapidly affects primitive hematopoiesis and impairs the maintenance of primitive HSC in non-obese mice. Not only our results uncover the impact of HFD independently of obesity but they also identify the disturbance of LR/TGF-β signaling-mediated quiescence as its main molecular mechanism of action.

S140

A NOVEL MODEL OF HUMAN LYMPHO-MYELOID PROGENITOR HIERARCHY BASED ON SINGLE CELL FUNCTIONAL AND TRANSCRIPTIONAL ANALYSIS

D. Karamitros[1,2,*], B. Stoilova[1,2], Z. Aboukhalil[1], A. Reinisch[3], F. Hamey[4], M. Samitsch[1], L. Quek[1,2,5], G. Otto[1], E. Repapi[1], J. Doondeea[1,2], B. Usukhbayar[1,2], J. Calvo[6], S. Taylor[1], N. Goardon[1], E. Six[7], F. Pflumio[6], C. Porcher[1], R. Majeti[3], B. Gottgens[4], P. Vyas[1,2,5]
[1]MRC, MHU, WIMM/NDCLS University of Oxford, [2]Oxford Biomedical Research Centre, Oxford, United Kingdom, [3]Division of Hematology, Stanford Institute for Stem Cell Biology and Regenerative Medicine, Stanford, United States, [4]Department of Haematology , Wellcome Trust-Medical Research Council Cambridge Stem Cell Institute, Cambridge, [5]Department of Haematology, OUH NHS Trust, Oxford, United Kingdom, [6]UMR967, INSERM/CEA/Universite Paris 7/Universite Paris 11, [7]UMR1163, Paris Descartes–Sorbonne Paris Cité University, Imagine Institute, , Paris, France

Background: Human hemopoiesis produces 10 billion new, terminally mature, blood cells daily; a production that is also rapidly responsive to external change. Dysregulation of this complex process can lead to hemopoietic and immune deficiencies and blood cancers. In humans the hemopoietic progenitor hierarchy producing lymphoid and granulocytic-monocytic (myeloid) lineages is unclear. Multiple progenitor populations give rise to lymphoid and myeloid cells but they remain incompletely characterized at the immunophenotypic, transcriptional and functional level.

Aims: Here, we aim to understand the clonal functional output and transcriptional programs of current primary human lympho-myeloid containing progenitor populations - the lymphoid-primed multi-potential progenitor (LMPP)[1], multilymphoid progenitor (MLP)[2] and granulocyte-macrophage progenitor (GMP).

Methods: We devised a FACS-staining and sorting strategy to prospectively purify eight human hematopoietic stem and progenitor cell (HSPC) populations. We compared function of LMPP, MLP and GMP *in vitro* by quantitative CFU assays, single cell liquid cultures or limit dilution analysis and *in vivo* by transplantation into humanized ossciles. We performed population RNA sequencing and single cell RT-PCR analysis to understand the relationship between functional and transcriptional heterogeneity.

Results: Our study comprehensively characterized the LMPP, MLP and GMP lympho-myeloid populations. Both LMPP and MLP are very rare within the mononuclear fraction (1 in 10^4 to 1 in 10^5). We cultured 3806 single LMPP, GMP and MLP cells (isolated from 21 cord blood units and equivalent to ~10^{11} mononuclear cells) under three different culture conditions. We observed marked functional heterogeneity in the three lympho-myeloid progenitor populations. Focusing on the wells that gave single cell initiated cultures the majority of cells from LMPP, MLP and GMP gave unilineage output (50-80%). Bi-lineage output was the next most common output, while multilineage output was rare and only seen from LMPP and GMP cells (9-15%). In vivo transplantation using a novel humanized ossicle assay increased the engraftment of lympho-myeloid progenitors 10-fold compared to previous reports. In vivo, the LMPP and GMP gave robust engraftment but the MLP substantially less engraftment. The LMPP gave rise to both GM and B cell engraftment, the GMP myeloid engraftment and the MLP mainly B cell output. RNA-Seq revealed distinct transcriptional signatures of these populations: MLP signature enriched for lymphoid-affiliated genes and transcription factors (TF), GMP gene signature enriched for myeloid-affiliated genes and TF and LMPP a hybrid lympho-myeloid signature. Analysis of the expression of 72 genes in 919 single LMPP, MLP and GMP shows that the 3 populations form a transcriptional continuum. Moreover, this analysis allowed us to further purify the myeloid potential of GMP population with the use of an alternative sorting strategy.

Summary/Conclusions: These data change our understanding of human hematopoiesis and propose a radically new model of lympho-myeloid progenitor specification. This model has important implications for human immune deficiencies and hemopoietic malignancies.

WILMS' TUMOR 1 RNA-ELECTROPORATED DENDRITIC CELL VACCINATION AS POST-REMISSION TREATMENT TO PREVENT OR DELAY RELAPSE IN ACUTE MYELOID LEUKEMIA: FINAL RESULTS OF A PHASE II STUDY IN 30 PATIENTS

Z. Berneman[1,*], S. Anguille[1], A. Van de Velde[1], V. Van Tendeloo[1], N. Cools[1], G. Nijs[1], B. Stein[1], E. Lion[1], A. Van Driessche[1], I. Vandenbosch[1], A. Verlinden[1], A. Gadisseur[1], W. Schroyens[1], K. Vermeulen[2], M.-B. Maes[2], K. Deiteren[2], R. Malfait[2], E. Smits[3]
[1]Hematology, [2]Laboratory Hematology, [3]Center for Cell Therapy and Regenerative Medicine, ANTWERP UNIVERSITY HOSPITAL, Edegem, Belgium

Background: Relapse is a major problem in acute myeloid leukemia (AML) and adversely impacts survival.
Aims: The aim of this phase II study was to determine the clinical efficacy of dendritic cell (DC) vaccine therapy in AML, and, more specifically, whether this form of immunotherapy can be applied in the post-remission adjuvant setting to decrease the risk of relapse following chemotherapy and to improve survival.
Methods: We vaccinated 30 AML patients in remission following poly-chemotherapy, but at very high risk of relapse with autologous DCs loaded with the Wilms' tumor 1 (WT1) antigen by means of mRNA electroporation, a technique that allows for human leukocyte antigen haplotype-independent, multi-epitope antigen presentation to T-cells. The vaccines were administered intradermally. *WT1* mRNA levels in blood and marrow were followed as a measure of minimal residual disease. Circulating WT1-specific CD8+T-cells obtained before vaccination and after the 4th dose of DCs were stained with WT1 peptide-HLA-A*0201 tetramers.To assess cell-mediated immunity *in vivo*, delayed type hypersensitivity (DTH) skin testing was performed 2 weeks after the 4th DC vaccination by intradermal injection; DTH-infiltrating lymphocytes collected from skin biopsies were expanded for 2-3 weeks in medium with interleukin-2, harvested and tested for WT1 specificity and reactivity.
Results: There was a demonstrable anti-leukemic response in 13/30 patients (overall response rate 43%). Nine patients achieved molecular remission as demonstrated by normalization of *WT1* transcript levels, 5 of which are sustained after a median follow-up of 109.4 months, including 1 patient who went from partial remission to complete remission by DC vaccination only. In the remaining 4 responding patients, the clinical response was characterized by stable disease as demonstrated by elevated but stable *WT1* transcript levels in blood for 3-12 months and stable blood values without blasts. Five-year overall survival was 40%, as compared to 24.7% in the SEER data of the National Cancer Institute; it was significantly higher in responders than in non-responders (53.8% *vs* 25.0%; *P*=0.01). In patients receiving DCs in first complete remission (CR1), there was a vaccine-induced relapse reduction rate of 25% and the 5-year relapse-free survival was significantly higher in responders than in non-responders (50% *vs* 7.7%; *P*<0.0001). In patients ≤65 and >65 years who received DCs in CR1, 5-year overall survival was 69.2% and 30.8% respectively. Of the 30 patients, 11 are alive in CR, including 5 who relapsed after DC vaccination; 2 proceeded to allogeneic stem cell transplantation, while the 3 other patients were brought back into CR by chemotherapy alone, 2 of them surviving more than 7 and 4 years respectively after reachieving CR. Long-term clinical response was correlated with increased circulating frequencies of poly-epitope WT1-specific tetramer+CD8+T-cells. Long-term overall survival was correlated with interferon-γ+and tumor necrosis factor-α+ WT1-specific responses in DTH-infiltrating CD8+T-lymphocytes.
Summary/Conclusions: Vaccination of AML patients with *WT1* mRNA-electroporated DCs can be an effective and non-toxic strategy to prevent or delay leukemia relapse after standard chemotherapy, translating into improved overall survival rates, which are correlated with the induction of WT1-specific CD8+T-cell responses.

FIRST-IN-HUMAN MULTICENTER STUDY OF BB2121 ANTI-BCMA CAR T CELL THERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA: UPDATED RESULTS

Y. Lin[1,*], J. Berdeja[2], N. Raje[3], N. Munshi[4], D. Siegel[5], M. Liedtke[6], S. Jagannath[7], M. Maus[3], A. Turka[8], L.P. Lam[8], K. Hege[9], R. Morgan[8], M.T. Quigley[8], J. Kochenderfer[10]
[1]Mayo Clinic, Rochester, MN, [2]Sarah Cannon Research Institute and Tennessee Oncology, Nashville, TN, [3]Massachusetts General Hospital Cancer Center, [4]Dana Farber Cancer Institute, Boston, MA, [5]Hackensack University Medical Center, Hackensack, NJ, [6]Stanford University Medical Center, Palo Alto, CA, [7]Mount Sinai Medical Center, New York, NY, [8]bluebird bio, Inc., Cambridge, MA, [9]Celgene, San Francisco, CA, [10]National Cancer Institute/NIH, Bethesda, MD, United States

Background: To test the safety and efficacy of the CAR T cell modality in relapsed/refractory multiple myeloma (MM), we have designed a second-generation CAR construct targeting B cell maturation antigen (BCMA) to redirect T cells to MM. bb2121 consists of autologous T cells transduced with a lentiviral vector encoding a novel CAR incorporating an anti-BCMA scFv, a 4-1BB costimulatory motif and a CD3-zeta T cell activation domain. We will report updated safety and efficacy results following promising initial results (Berdeja *et al.*, ENA 2016).
Aims: The primary objective is to determine the maximally tolerated dose of bb2121 in subjects with MM whose tumors express BCMA, to determine and test a recommended phase 2 dose for future studies. The secondary objective is to provide preliminary efficacy data on the anti-tumor effects of treatment with bb2121 in subjects with MM whose tumors express BCMA.
Methods: CRB-401 (NCT02658929) is a multi-center phase 1 dose escalation trial of bb2121 in patients with relapsed and/or refractory MM who have received ≥3 prior regimens, including a proteasome inhibitor and an immunomodulatory agent, or are double-refractory, and have ≥50% BCMA expression on plasma cells. Peripheral blood mononuclear cells are collected via leukapheresis. Patients undergo lymphodepletion with Flu (30 mg/m^2) Cy (300 mg/m^2) daily for 3 days then receive 1 infusion of bb2121. The study follows a standard 3+3 design with planned dose levels of 5.0, 15.0, 45.0, 80.0 and 120 x 10^{7}CAR+T cells.
Results: Asof November 18, 2016, 11 patients had been infused with bb2121 in the first 4 dose cohorts, and 9 patients had reached at least 1 month of follow-up. As of data cut-off, no dose limiting toxicities, and no >Grade 2 neurotoxicities or cytokine release syndrome (CRS) had been observed. Grade 1-2 CRS has been reported in 8/11 (73%) treated patients. All patients treated with doses of 15.0 x 10^7 or higher remained on study and the overall response rate (ORR) in the 9 evaluable patients is 100%, including 2 sCRs and 2 MRD-negative responses (sCR and VGPR). CAR+T cell expansion has been demonstrated consistently. An additional 6 months of follow up on reported results and initial data from an additional ~10 patients will be presented.
Summary/Conclusions: bb2121 shows promising efficacy at dose levels above 5.0 x 10^{7}CAR+T cells, including 2 sCRs and ongoing clinical responses at 6 months with mild and manageable CRS to date. These initial data support the potential of CAR T therapy with bb2121 as a new treatment paradigm in MM.

S143

BASELINE AND EARLY POST-TREATMENT CLINICAL AND LABORATORY FACTORS ASSOCIATED WITH SEVERE NEUROTOXICITY FOLLOWING 19-28Z CAR T CELLS IN ADULT PATIENTS WITH RELAPSED B-ALL

J. Park[1,*], I. Riviere[1], X. Wang[1], B. Senechal[1], Y. Wang[1], B. Santomasso[1], M. Sadelain[1], R. Brentjens[1]
[1]Memorial Sloan-Kettering Cancer Center, New York, United States

Background: CD19-specific chimeric antigen receptor (CAR) modified T cells produce high anti-tumor activity in relapsed or refractory (R/R) ALL, but can be associated with cytokine release syndrome (CRS) and neurotoxicity (NTX).
Aims: We examined baseline and post-treatment clinical and laboratory parameteres to identify factors associated with severe NTX (≥Grade 3) in our phase I clinical trial of CD19-specific 19-28z CAR T cells for adult patients (pts) with R/R B-ALL (NCT01044069).
Methods: 51 adult pts with R/R B-ALL were treated with 19-28z CAR T cells following conditioning chemotherapy at MSKCC. In order to identify clinical and serum biomarkers associated with severe NTX (sNTX), we examined demographic, treatment, and clinical blood parameters as well as *in vivo* CAR T expansion and serum cytokines, and performed univariate and multivariate analysis.
Results: In this cohort of ALL pts, 20, 8, 2, 18 and 3 pts experienced Gr 0, 1, 2, 3, and 4 NTX, respectively. No pt developed grade 5 NTX and no cerebral edema was seen. Disease burden (≥50% blasts) at the time of T cell infusion (p=0.0045) and post-treatment ≥Gr3 CRS (p=0.0010) were significantly associated with sNTX, but we found no association with age, weight, T cell dose, choice of conditioning chemotherapy (Flu/Cy s. Cy), and prior lines of treatment. Among the clinical and blood parameters, fever, low PLT, high ferritin and MCHC as well as elevated GM-CSF, IFNγ, IL-15, IL-5, IL-10, IL-2 at day 3 of T cell infusion at day 3 of T cell infusion were significantly associated with sNTX (all p<0.01). While some of these cytokines were also elevated in severe CRS cases, IL-5 and IL-2 at day 3 were unique to sNTX. Furthermore, *in vivo* peak CAR T expansion at day 7 (p=0.0001) significantly correlated with sNTX (p<0.01). Lastly, multivariate analysis revealed baseline PLT <60 or MCHC >33.2% and morphologic disease (>5% blasts) has 95% sensitivity and 70% specificity of identifying sNTX pts.
Summary/Conclusions: These data provide a characterization of early clinical and serum biomarkers of sNTX in adult pts receiving 19-28z CAR T cells and should help identify appropriate pts for early intervention strategy to mitigate NTX.

S144

FIRST EVIDENCE DEMONSTRATING ENGRAFTMENT AND REPOPULATION ADVANTAGE OF GENE-CORRECTED HEMATOPOIETIC REPOPULATING CELLS IN NON-CONDITIONED FANCONI ANEMIA PATIENTS

J. Sevilla[1,*], P. Rio[2], S. Navarro[2], E. Galvez[3], E. Sebastian[3], G. Guenechea[2],

R. Sanchez[2], A. Catala[4], J. Surralles[5], F. Mavilio[6], M.L. Lamana[2], R. Yañez[2], R. López[7], A. Galy[6], J.A. Casado[2], J.C. Segovia[2], N. Garcia de Andoin[8], P. Ruiz[9], C. Diaz de Heredia[10], J. Bueren[2]
[1]Servicio Hematologia y Oncología Pediátricas., Hospital Infantil Universitario Niño Jesús. FIB HIUNJ. CIBERER, [2]Hematopoietic Innovative Therapies, CIEMAT/CIBERER/IIS. Fundación Jiménez Díaz, [3]Servicio Hematologia y Oncología Pediátricas., Hospital Infantil Universitario Niño Jesús, Madrid, [4]Hospital San Joan de Deu, [5]Autónoma University of Barcelona/CIBERER, Barcelona, Spain, [6]Genethon, Evry, France, [7]Hospital de Cruces, Bilbao, [8]Hospital de Donostia, Donostia, [9]Hospital Materno Infantil, Málaga, [10]Hospital Vall d'Hebron, Barcelona, Spain

Background: Fanconi anemia (FA), is a monogenic inherited syndrome associated with bone marrow failure (BMF), that has been considered a candidate disorder for hematopoietic stem cell (HSC) gene therapy. Up to date, three clinical trials have been performed, all of which failed to demonstrate engraftment of corrected HSCs.
Aims: To demonstrate engraftment of gene-corrected HSCs in non-conditioned Fanconi anemia patients.
Methods: To improve previous results, we proposed a new approach based on two clinical trials. First, to increase the HSC collection, we designed a trial employing a plerixafor plus G-CSF mobilization regimen. Second, to improve the quality of corrected HSCs, cells were pre-stimulated for only 8-10 hours and transduced with a new lentiviral vector (PGK-FANCA.Wpre*) for 12-14h, a substantially shorter duration than in previous trials. To avoid chemotherapy-induced damage, a conditioning regimen was not included in the trial, based on the expected proliferative advantage of autologous corrected HSCs.
Results: Eight patients have been included so far in the HSC collection trial. No severe adverse events (SAE) related to the procedure have been reported. The most relevant AE has been the transfusion of packed red blood cells and platelets. Six FA patients aged 3-6 years underwent collections after mobilization of significant numbers of CD34+cells (10 to 70 CD34+cells/μL) to peripheral blood. Two patients (15 and 16 years) failed to mobilize. On average, 5 million CD34+cells/Kg were collected, with 45% recovery after immunoselection. In the first patient included in the gene therapy trial, fresh immunoselected CD34+cells were transduced with the therapeutic vector. Subsequently, two patients, were infused with transduced CD34+cells that remained cryopreserved for almost 2 years. Infused cell products contained 0.5 to 1.4 million CD34+cells/kg, and vector copy numbers per cell (VCN/cell) that ranged between 0.17 to 0.45. To-date, there has been no SAE related to the procedure. Engraftment of gene corrected cells has been observed in the three patients. Notably, increased gene marking levels and significant phenotypic correction in the hematopoietic progenitor cells, deduced from the acquired resistance of the colony forming cells to mitomycin C (15% of BM CFCs survived to 10 nM MMC), have been demonstrated after 9 months of follow up in one of the patients.
Summary/Conclusions: Our preliminary results show that 1) HSCs collection is both safe and efficient in very young FA patients after mobilization with G-CSF and plerixafor, and 2) Engraftment and proliferation advantage of gene-corrected HSPCs has been demonstrated in FA patients even in the absence of conditioning regimens.
The long-term follow up of patients included in these clinical trials will demonstrate the feasibility of restoring the hematopoietic function of FA patients by means of a gene therapy approach in the absence of conditioning.

S145

TARGETING FLT3 WITH CHIMERIC ANTIGEN RECEPTOR T CELLS CONFERS POTENT REACTIVITY AGAINST ACUTE MYELOID LEUKEMIA

H. Jetani[1,*], I. Garcia-Cadenas[2], T. Nerreter[1], J. Sierra[2], W. Herr[3], S. Thomas[3], H. Einsele[1], M. Hudecek[1]
[1]Internal Medicine II, University Hospital Würzburg, Würzburg, Germany, [2]Servicio de Hematología, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [3]Klinik und Poliklinik für Innere Medizin III, Universitätsklinikum Regensburg, Regensburg, Germany

Background: Adoptive immunotherapy with chimeric antigen receptor (CAR)-modified T cells has therapeutic potential in hematologic malignancies. We are pursuing FMS like tyrosine kinase 3 (FLT3) as a novel CAR target in acute myeloid leukemia (AML). FLT3 is a homodimeric transmembrane protein with uniform expression on AML, irrespective of cytogenetic and histomorphologic subtype. FLT3 provides survival signals to AML blasts and is a key driver of leukemia-genesis in AML cases with internal tandem duplication (FLT3-ITD). These attributes suggest FLT3 may be an 'Achilles heel', making AML blasts susceptible to CAR T-cell mediated recognition and elimination.
Aims: We therefore explored the anti-leukemia efficacy of FLT3-CAR modified T cells against FLT3-ITD+and FLT3 wild type AML in pre-clinical models *in vitro* and *in vivo*.
Methods: A FLT3-CAR comprising a single-chain variable fragment (4G8), fused to an IgG-Fc spacer, and signaling module with CD3 zeta and CD28 was encoded in a lentiviral vector (epHIV7) for gene-transfer into CD8+and CD4+T cells of healthy donors (n>4) and AML patients. CAR T-cell mediated cytolytic activity was evaluated in FACS-/luminescence-based assays, cytokine production analyzed by ELISA and proliferation assessed by CFSE dye dilution. Immunodeficient NSG mice were engrafted with AML cell line (Molm-13) or primary AML blasts and treated with $5x10^6$CAR-modified or control T cells (CD8:CD4 ratio=1:1).
Results: We confirmed specific recognition and high-level cytolytic activity of CD8+FLT3-CAR T cells against a panel of AML cell lines including THP-1 (FLT3 wild type), and Molm-13 (FLT3-ITD heterozygous). Both CD8+and CD4+FLT3-CAR T cells produced IFN-γ and IL-2, and underwent proliferation after antigen stimulation. FLT3-CAR T cells that we prepared from AML patients exerted specific anti-leukemia reactivity against autologous primary AML blasts, with near-complete cytolysis within 24 hours of co-culture. Further, FLT3-CAR T cells conferred a potent anti-leukemia effect in *in vivo* models of systemic leukemia, both with AML cell lines (Molm-13) and primary AML blasts. A single dose of FLT3-CAR T cells conferred complete eradication of leukemia from peripheral blood, bone marrow and spleen, as confirmed by bioluminescence imaging and flow cytometry. FLT3 is not expressed in any normal solid tissues and mature hematopoietic cells, but shows limited expression in hematopoietic progenitors and hematopoietic stem cells (HSCs). Preliminary data show that FLT3-CAR T cells recognize FLT3+/high normal HSCs and interfere with normal hematopoiesis, but preserve a proportion of HSCs capable of reconstituting hematopoietic lineages. Studies to assess recognition of normal HSCs *in vivo* are ongoing.
Summary/Conclusions: Collectively, our data demonstrate that T cells expressing a FLT3-specific CAR mediate potent reactivity against FLT3 wild type and FLT3-ITD+AML *in vitro* and *in vivo*, and establish FLT3 as a novel CAR target in AML. FLT3-ITD positivity identifies a high-risk AML subgroup that may particularly benefit from adoptive therapy with FLT3-CAR T cells, *e.g.* in order to achieve 'minimal residual disease' (MRD) negativity prior to allogeneic HSC transplantation. Our data further suggest that in contrast to CD33 and CD123, which are pursued as alternative CAR targets in AML, targeting of FLT3 may preserve a fraction of normal HSC and enable the implementation of CAR therapy outside the transplant setting.

BPX-501 DONOR T CELL INFUSION (WITH INDUCIBLE CASPASE 9 SUICIDE GENE) FACILITATES HLA-HAPLOIDENTICAL STEM CELL TRANSPLANT IN CHILDREN WITH BOTH HEMATOLOGICAL MALIGNANCIES AND NON-MALIGNANT CONDITIONS

M. Algeri[1,*], S. Naik[2], N. Kapoor[3], K. Mahadeo[4], V. Aquino[5], A. Woolfrey[6], A. Bertaina[1], P. Merli[1], A. Woolfrey[6], F. Galaverna[1], K. Mahadeo[7], S. Baumeister[8], E. Nemecek[9], W. Qasim[10], D. Pagliara[1], G. Li Pira[1], L. Krishnamurti[11], D. Jacobsohn[12], M. Slatter[13], J. Weinberg[14], A. Moseley[14], F. Locatelli[1]
[1]Ospedale Pediatrico Bambino Gesu, Rome, Italy, [2]Texas Children's Hospital, Houston, [3]Children's Hospital of Los Angeles, Los Angeles, [4]Childrens Hospital at Montefiore, Bronx, [5]UT Southwestern, Dallas, [6]Fred Hutchinson Cancer Research Center, Seattle, [7]Children's Hospital at Montefiore, Bronx, [8]Dana Farber Cancer Institute, Boston, [9]Oregon Health & Science University , Portland, United States, [10]Great Ormond Street Hospital, London, United Kingdom, [11]Children's Hospital of Atlanta, Atlanta, [12]Children's National Health System, Washington, DC, United States, [13]Great North Children's Hospital, Newcastle, United Kingdom, [14]Bellicum Pharmaceuticals Inc., Houston, United States

Background: Allogeneic haploidentical hematopoietic stem cell transplant (HSCT) offers curative therapy for children who lack an available HLA-identical donor with hematopoietic disorders such as Primary Immune Disorders (PIDs), hemoglobinopathies, erythroid disorders and acute leukemias. αβ T-cell depletion mitigates the risk of GVHD after haplo-HSCT, but is associated with extended immunodeficiency, leading to complications due to infections . We have performed αβ TCR-depleted haplo-HSCT with post-transplant infusion of BPX-501 gene modified T cells to allow for more rapid immune reconstitution. Upon occurrence of GVHD, administration of rimiducid (AP1903) dimerizes the Caspase 9 suicide switch and rapidly induces apoptosis of the transduced BPX-501 cells and mitigates the GVHD.
Aims: This study was performed to determine the impact of BPX-501 T cell infusion on outcomes (treatment related mortality (TRM), disease recurrence, GvHD incidence and immune reconstitution) after HSCT.
Methods: We report on a large multicenter, prospective Phase I-II study enrolling children receiving αβ T-cell depleted Haplo-HSCT. Patients were infused with BPX-501 T cells 2 weeks post-transplant. 104 patients have >100 day follow-up, 81 patients have follow up ≥180 days and 51 with >1 year follow-up. All patients received myeloablative therapy and low dose ATG prior to transplant. No pharmacologic GvHD prophylaxis was given (Table 1).

Table 1. Diagnoses of Patients with >100 day follow-up.

Non-Malignant	N=66	Malignant	N=38
SCID	11	ALL(3 CR1, 21 CR2)	24
WAS	6	AML	14
CGD	4		
Thalassemia Major	8		
Sickle Cell Disease	4		
Fanconi Anemia	8		
HLH	5		
Others	20		

Results: Cumulative incidence of TRM remains very low at 100 days (0%), 180 days (1.6%) and 1 year (2.8%). Of the 81 patients with >180 day follow-up, 20 patients had acute GvHD 1-3 (24.7%) (Figure 1A); 10 with Grade 1, 8 with Grade 2, 2 with Grade 3 and one Grade 4 skin. Mild cGvHD was seen in 2 patients, moderate cGvHD in 2 patients and one case of severe cGvHD in a malignant patient, attributed to the allograft, not BPX-501. Rimiducid was used in 4 patients with Grade 2 GvHD with rapid resolution of symptoms, as it did in the severe cGvHD patient. In both malignant and non-malignant patients. CD3, CD4, CD8 (Figure 2B) and B cells (Figure 3C) immune reconstitution was brisk. CD3+/CD19+ T-cells were detectable at one year via flow cytometry analysis of peripheral blood. In Wiskott-Aldrich patients, platelet recovery remains in the normal range at 180 days with mean platelet counts of $246.3x10^3$/uL. At 180 days and 1 year, the patients with hemoglobinopathies remain transfusion-free with a normal mean HgB value of 11.4 g/dL.
Summary/Conclusions: These data suggest that infusion of BPX-501 modified T cells may facilitate T cell depleted Haplo-HSCT in children who would benefit from HSCT for either malignant or non-malignant conditions. The availability of a suicide gene mechanism in donor T cells infused after T depleted Haplo-HSCT, results in low rates of infection and rapidly reversible GvHD when the dimerizer is infused to activate the suicide switch. Rapid cellular and humoral immune reconstitution makes BPX-501 after T depletion a safe and viable option for children who do not have a matched donor transplant and in whom transplantation has been deemed curative.

[1]CRISPR Therapeutics, Cambridge, [2]Cell Therapy Group, Madison, CT, [3]Vertex Pharmaceuticals Incorporated, Boston, [4]Stanford University, Stanford, [5]Rice University, Houston, United States, [6]Genethon, Evry, [7]INSERM, [8]Imagine Institue, Paris, France

Background: Extensive human genetic and epidemiological data demonstrate that the genetic condition Hereditary Persistence of Fetal Hemoglobin (HPFH) substantially ameliorates the pathology of Sickle Cell Disease (SCD) and β-thalassemia (β-Thal). This condition is associated with several genetic variants at the β-globin locus that lead to transcriptional reactivation of γ-globin genes, resulting in upregulation of fetal hemoglobin (HbF).
Aims: CRISPR/Cas9 is a revolutionary technology that allows for precise, directed changes to genomic DNA. Our strategy is to use CRISPR/Cas9 in human primary $CD34^+$ hematopoietic stem and progenitor cells (HSPCs) to re-create specific HPFH genetic variants as well as other variants associated with elevated HbF and demonstrate their causal relationship to elevated HbF as a potential therapeutic strategy to treat SCD and β-Thal.
Methods: Using CRISPR/Cas9 gene editing, we have successfully re-created genetic variants linked to high HbF levels in HSPCs from healthy donors and SCD and β-Thal patient samples, and determined the relationship of different genetic variants to upregulation of γ-globin in bulk and clonal populations of differentiated erythrocytes. Off-target editing was assessed, and on-target editing in long-term repopulating subsets of HSPCs was measured *in vitro* and by engraftment in immunocompromised mice. Finally, editing rates at clinical scale in a GMP-capable manufacturing facility were demonstrated.
Results: We first optimized cell culture and electroporation conditions that led to high rates of genomic editing across multiple loci, achieving 84.9±6.2% (Mean±SD) editing efficiency at key regions of interest in $CD34^+$ HSPCs from mobilized peripheral blood of healthy donors (n=16). Similar rates of editing were attained using $CD34^+$ HSPCs derived from healthy-donor bone marrow (n=6). Cas9 delivery as recombinant protein improved cell viability when compared to mRNA-based delivery (88.8±3.7% compared to 75.5±9.3%, Mean±SD, n=56 for each) with no observed reduction in editing efficiencies. To investigate gene editing impact on HbF, edited cells were erythroid differentiated from healthy donors as well as from SCD and β-Thal patients. Specific gene edits significantly increased γ-globin mRNA expression to therapeutically-relevant levels (increased expression to 29-37% as a ratio of γ/α in one β-Thal patient sample and to 25-45% as a ratio of γ/(γ+β) in six SCD patient samples). We demonstrated similarly high rates of editing in the $CD34^+CD38^-CD90^+CD45RA^-$ long-term repopulating HSPCs and bulk $CD34^+$ HSPCs (87.9±6.4% compared to 89.7±3.6%, Mean±SD, n=4). We confirmed that engraftment levels of edited cells in immunocompromised mice were similar to control cells (% human CD45 in peripheral blood = 28.6±6.9% in controls *versus* 27.1±6.6% and 26.3±7.9% for two guide targets, Mean±SD, n=48 for each). In-depth off-target analysis

for a selected guide RNA confirmed no detectable genomic cleavage at over 5000 predicted off-target sites with a detection sensitivity of 0.2%, supporting its safety for clinical use. Finally, we have demonstrated editing rates of >85% at clinical scale in a GMP-capable manufacturing facility to enable clinical development for SCD and β-Thal. Required safety toxicology studies are ongoing.
Summary/Conclusions: Using CRISPR/Cas9 we successfully created gene edits that upregulate HbF in both healthy donor and patient samples. We have also dissected the genotype-phenotype relationship for specific genetic modifications, identifying the editing strategies which are most promising for re-expressing HbF. We have optimized the conditions for modifying HSPCs, including at clinical scale in a GMP-compliant setting, and demonstrated potential safety with no detectable off-target editing. These experiments support the further development of specific CRISPR/Cas9 editing strategies of HSPCs to treat SCD and β-Thal patients.

EXPOSURE TO INFECTION TRIGGERS PAX5 AND ETV6-RUNX1 CHILDHOOD BCP-ALL

A. Martín-Lorenzo[1], F. Auer[2], G. Rodríguez Hernández[1], S. Bhatia[2], I. García-Ramírez[1], D. Schäfer[2], C. Vicente-Dueña[1], A. Borkhardt[2], I. Sánchez-García[1], J. Hauer[2,*]
[1]Experimental Therapeutics and Translational Oncology Program, Instituto de Biología Molecular y Celular del Cáncer, CSIC/ Universidad de Salamanca and Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain, [2]Department of Pediatric Oncology, Hematology and Clinical Immunology, Heinrich Heine University, Duesseldorf, Germany, Duesseldorf, Germany

Background: B-cell precursor acute lymphoblastic leukemia (BCP-ALL) of childhood remains a major cause of death in high-income countries. It has a yet unexplained peak incidence between 2-6 years of age and a potential trigger was theorized a century ago with several possibilities of exposure to infection in infancy. Recently *in vitro* and *in vivo* evidence strengthened the causal role of exposure to infection in BCP-ALL (1, 2). However, it remains unknown which molecular BCP-ALL subtype can be triggered by exposure to infection and how the pre-leukemic clone evolves to BCP-ALL.
Aims: Aiming to understand the role of infection exposure in the etiology of childhood BCP-ALL.
Methods: We have developed and characterized two independent GEMMs, in addition to the *Pax5*+/- infection model (1), which were exposed to a common infection environment. These represent childhood *BCR-ABL1^{p190}* BCP-ALL and the most common subtype *ETV6-RUNX1* BCP-ALL. Both model systems ensure Sca1-directed expression of *BCR-ABL1^{p190}* or *ETV6-RUNX1* in HSC/PC in C57BL/6 x CBA mice and were characterized extensively with respect to clinical, immunephenotypic and molecular genetic characteristics. Whole exome (WES) and whole genome sequencing (WGS) was performed of murine BCP-ALL on a HiSeq 2500 (Illumina) platform.
Results: *Pax5*+/- and *Sca1-ETV6-RUNX1* mice develop BCP-ALL only after exposure to common pathogens whereas *BCR-ABL1^{p190}*micedevelop BCP-ALL independent of exposure to common infection. The molecular mechanism leading to BCP-ALL identified in the infection dependent GEMMs is determined by the genetic predisposition (*Pax5*+/- or *ETV6-RUNX1*). Pax5+/- mice acquire constitutive activating *Jak3* mutations (6/9) in a susceptible B-cell precursor population ((pro+pre)-B and immature B cells) (1). On the other hand *Sca1-ETV6-RUNX1* mice develop BCP-ALL at a low penetrance (10.75%; 10 out of 93) with a CD19^{+}B220^{+}IgM^{-} cell surface phenotype and manifested with blast cells in the peripheral blood (PB) and clonal immature BCR rearrangement. High expression of Recombination Activating Gene 1 (*Rag1*) and loss of function mutations in *Ebf1* were identified in murine BCP-ALL and are well known in the context of human *ETV6-RUNX1* leukemia. Additionally we identified a high proportion of mutations in genes implicated in histone modification, *i.e. Kdm5c* (no. J408) causing a premature stop. CRISPR-Cas9 knock down studies of KDM5C in a precursor B-cell line revealed facilitated Rag1/2 binding to the histone complex (H3K4me3) as a potential molecular mechanism inducing Rag1 off target activity in pre-leukemic *ETV6-RUNX1* HSC/PC after exposure to infection. In contrast to *Pax5*+/- and *Sca1-ETV6-RUNX1* mice, *Sca1-BCR-ABL1^{p190}* mice develop BCP-ALL independent of exposure to common pathogens by reprogramming of a HSC/PC and subsequent loss of *Pax5*.
Summary/Conclusions: In summary, exposure to common pathogens can trigger childhood BCP-ALL based on Pax5 loss of function or the common *ETV6-RUNX1* rearrangement. However the underlying molecular mechanism (Jak-Stat signaling in *Pax5*+/- mice and histone modification in *ETV6-RUNX1* mice) triggered by exposure to common infection is determined by the genetic predisposition. On the other hand BCP-ALL, which emerge on the basis of a potent oncogene (such as *BCR-ABL1^{p190}*) can develop independent of exposure to infection. These findings are important for encouraging the prospect of novel interventions that might help to prevent or treat a significant proportion of childhood BCP-ALLs.

REVERSIBLE PHARMACOLOGICAL TARGETING OF RHOA ALLOWS IMPROVED STORAGE, SURVIVAL AND HEMOSTATIC ACTIVITY OF PLATELETS *IN VITRO* AND *IN VIVO*, IN MICE AND IN PRIMATES

S. Hegde[1,2,*], H. Akbar[3], S. Nestheide[1], A. Wellendorf[2], F. Mohmoud[1], J. Johnson[2], Y. Zheng[2], J. Cancelas[1,2]
[1]Hoxworth Blood Center, University of Cincinnati College of Medicine, [2]Experimental Hematology, Cincinnati Children's Hospital Medical Center, Cincinnati, [3]Ohio University, Athens, United States

Background: The use of platelets in transfusion has increased dramatically in the last three decades. Cold temperature induces changes in glycosylation and clustering of platelet glycoprotein (GP) Ib and cytoskeletal rearrangements, which are recognized by host receptors resulting in lectin-mediated platelet phagocytosis and clearance from circulation. As a result, current practice of platelet storage for transfusion uses room temperature and associates with a relatively high risk of bacterial growth and infection in susceptible patients.
Aims: Due to the cytoskeletal nature of the platelet changes upon refrigeration, we hypothesized that the RHO family GTPase activity is pivotal in the cold platelet lesion. Targeted intervention may benefit refrigerated storage.
Methods: Analysis of RhoA, Rac1 and Cdc42 activity was performed using GST-Rhotekin and GST-PAK effector domain pulldown assays. Platelets were obtained from anticoagulated (CPD or EDTA) human, Rhesus monkey and murine whole blood. G04, NSC23766 and Casin, specific inhibitors for RhoA, Rac and Cdc42, respectively, were titered and used at concentrations of 75 mcM, 50 mcM and 10 mcM, respectively. RhoA deficient murine platelets were obtained from polyI:C-treated *Mx1-Cre;RhoA $^{f/f}$* mice. Aspirin was administered at a dose of 5 mg/Kg b.w. to mice and monkeys. Bleeding time was performed using standard animal protocols. Transfused human/monkey platelets were stored in plasma or PAS-III (67%)/plasma(33%) at RT or 1-9C for 7 days or 1-4 hours for murine platelets.
Results: We found that either short- or long-term refrigeration activates RHOA and RAC1, but not CDC42. Genetic deletion of RhoA or RHOA inhibition with the small molecule inhibitor G04 suffices to completely prevent cold-induced platelet clearance after long-term cold storage of murine or human platelets. The effect of G04 is on-target since it mimics but does not modify the response of RhoA-deficient platelets. The effect of G04 is reversible since removal of G04 after 7-day storage restores RHOA activity to normal levels and allows normal extent of shape change and spreading on fibrinogen. To analyze the kinetics and hemostatic activity of cold stored inhibitor treated human platelets after xenotransfusion, we analyzed the survival of xenotransfused human platelets after long term (7-day) refrigeration in the presence and absence of inhibitors cocktail or individual inhibitors in macrophage depleted, sub-lethally irradiated NSG mice (N=20/group) as well as autologously transfused platelets in a crossover trial in Rhesus monkeys (n=5). Our results show that reversible inhibition of RHOA in refrigerated platelets suffices to survival levels similar to the unrefrigerated control in 100% of mice and 80% of monkeys ($p<0.001$). Our data further show that washing of platelets stored for 7 days in G04/plasma maintains collagen–induced shape change as well as normal aggregation of human platelets and restores bleeding time correction after congenic or autologous transfusion in all aspirinated mice and 80% of aspirinated Rhesus monkeys, respectively. RHOA inhibition blocks the process of intracellular traffic of GP through lipid rafts and endocytotic intermediates as assessed by confocal microscopy of GpIb and the vacuolar sorting protein VPS33b, as well as biochemical fractionation of detergent-insoluble membrane lipid rafts, resulting in reduced blebbing and formation of microparticles upon storage in G04/plasma.
Summary/Conclusions: We demonstrate that activation of RHOA is a pivotal mechanism of refrigerated platelet storage lesion and phagocytosis. Reversible inhibition of RHOA allows the extended cold storage of platelets which are effective *in vitro* and *in vivo*, suitable for use in clinical safety and efficacy trials. Our study also provides the mechanism and a stringent proof-of-principle for the translational application of a novel approach to refrigerated platelet storage.

versity of Heidelberg, Heidelbarg, [9]Department of Internal Medicine III, University Hospital of Ulm , Ulm, [10]Medizinische Klinik, Städtisches Klinikum , Medizinische Klinik, Städtisches Klinikum , Karlsruhe, [11]University Hospital Hamburg-Eppendorf, Hamburg, [12]Zentrum für Innere Medizin, Hämatologie/ Onkologie, Charité Campus Mitte, Berlin, Germany, [13]Cantonal Hospital Baselland, Liestal, [14]Swiss Group for Clinical Cancer Research (SAKK), [15]ChurInselspital, Bern University Hospital, Bern, Switzerland, [16]Department of Radiotherapy, University Hospital of Münster, Münster, [17]Department of Radiotherapy, University Hospital of Cologne, Cologne, [18]Berlin Reference Center for Lymphoma and Haematopathology, Berlin, Germany

Background: The German Hodgkin Study Group (GHSG) applies the intensive eBEACOPP regimen (dose-escalated bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, and prednisone) to all newly diagnosed advanced-stage HL patients regardless of their individual risk-profile. However, some patients might not be in need of such an intensive treatment to achieve cure. Unfortunately, baseline risk factors as defined in the international prognostic score cannot identify these patients reliably. Recent clinical research suggests that early metabolic response assessment after 2 cycles of therapy using FDG-PET (PET-2) can better predict the individual outcome. In particular, a rapid response as determined by PET-2 negativity might allow reducing the overall treatment intensity.

Aims: To assess the feasibility of decreasing the number of eBEACOPP cycles in patients with negative PET-2 without loss of efficacy as determined by progression-free survival (PFS).

Methods: Between 05/2008 and 07/2014, we recruited patients with newly diagnosed, advanced-stage HL aged 18–60 years. All patients gave written consent before study entry. PET-2 was centrally assessed with FDG uptake not higher than the mediastinal blood pool defined as negative. Patients with negative PET-2 were randomly assigned to receive 6 or 2 additional cycles (*i.e.* 8 or 4 cycles of eBEACOPP in total, respectively). PET-positive residues after chemotherapy were irradiated. Based on the results of our previous HD15 trial, the protocol was amended in June 2011 and the standard therapy was reduced from 8 to 6 cycles of eBEACOPP in total. The trial was designed to exclude inferiority of 6% or more of the experimental treatment (4 cycles of eBEACOPP) compared with the pooled standard treatment (8 or 6x cycles of eBEACOPP) at 5 years.

Results: We enrolled 2,101 patients. 1,005 patients with negative PET-2 were randomly assigned to either 8/6 cycles of eBEACOPP (n=504) or 4 cycles of eBEACOPP (n=501). With a median follow-up of 55 months, estimated 5-year PFS in the per-protocol set was 90.8% (87.9–93.7) with 8/6 cycles of eBEACOPP and 92.2% (89.4–95.0) with 4 cycles eBEACOPP (difference +1.4%, 95% CI -2.7–5.4, excluding the non-inferiority margin of -6%). In the standard arm, 95% of patients had at least one acute hematological toxicity of CTCAE grade 3-4 compared with 90% in the experimental arm, including severe infections in 75 (15%) and 40 (8%) patients, respectively. Acute severe organ toxicities were documented for 91 (18%) and 38 (8%), respectively. 25 patients (5%) in the standard group (8/6 cycles of eBEACOPP and 9 (2%) in the experimental group (4 cycles of eBEACOPP) died; most frequent cause of death was second malignancy (11 and 1 patient, respectively). No patient in the experimental group died from treatment-related toxicities. Estimated 5-year overall survival (OS) in the per-protocol set was 95.4% (93.4–97.4) with standard eBEACOPP, and 97.7% (96.2–99.3) with 4 cycles of eBEACOPP (log-rank p=0.004).

Summary/Conclusions: Metabolic response assessment using FDG-PET after 2 cycles of eBEACOPP allows the reduction from therapy with 8/6 to only 4 cycles without loss of efficacy as determined by PFS in advanced-stage HL patients. Furthermore, the abbreviated treatment with 4 cycles of eBEACOPP is associated with improved tolerability and consequently leads to a significant OS benefit over standard therapy. PET-guided reduced therapy with eBEACOPP combines outstanding efficacy with high safety. We therefore recommend this treatment strategy for advanced-stage HL patients.

Acute lymphoblastic leukemia - Biology 1

P151

TARGETED SINGLE CELL SEQUENCING TO IDENTIFY MUTATIONAL HIERARCHY IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

J. De Bie[1,*], S. Demeyer[1], E. Geerdens[1], A. Uyttebroeck[2], N. Boeckx[3], J. Cools[1]
[1]CME, KU Leuven, [2]Pediatric Oncology, [3]Laboratory Medicine, UZ Leuven, Leuven, Belgium

Background: Acute lymphoblastic leukemia (ALL) is a common childhood malignancy caused by clonal proliferation of immature B or T lymphoid cells. ALL patients are primarily young children who respond well to chemotherapy, with survival rates above 85%. However, if relapse develops, survival rates drop to 15-50%. Recent studies have shown that at diagnosis, different ALL subclones are present that are likely the result of clonal branched evolution. Understanding this clonal evolution and the order at which mutations are acquired can provide improved insights into the origins of leukemia relapse.
Aims: To use single-cell sequencing to investigate (i) the heterogeneity of leukemic T-ALL cells present at diagnosis and (ii) unravel the order in which mutations were acquired during leukemia evolution.
Methods: Bone marrow samples taken at diagnosis and remission from 4 T-ALL patients underwent whole genome and RNA sequencing. Somatic mutations, indels and chromosomal translocations were confirmed using Sanger sequencing. Primers were designed to specifically target these genetic alterations, and included 40 primers against heterozygous SNPs for quality control assessment. A total of 1517 single cells (average of 379 cells per patient), were sorted using flow cytometry or a microfluidic device and analyzed with targeted sequencing. Cells were discarded from further analysis if locus and allelic drop-out exceeded 33,3%. Jaccard hierarchical clustering was applied to identify subclones and a new graph-based algorithm was developed to determine the order of mutation acquisition. Single $CD34^+CD38^-$ hematopoietic stem/progenitor cells (HSPCs) from the same samples were also isolated to test for the presence of mutations in early progenitors.
Results: We detected between 2 and 4 separate clones in each T-ALL patient sample. Every patient harboured one dominant clone comprising 46 to 98% of all single cells that was highly mutated, accompanied by a number of smaller subclones carrying fewer mutations. No mutually exclusive mutations, fusion genes or deletions were observed between the clones arguing against independent leukemic clonal initiation events. Instead, a more stepwise clonal hierarchy became likely, with each clone harbouring more mutations than the last. Using our newly developed graph-based algorithm, we found that early mutations mostly occurred in genes of unknown significance and may represent a pre-leukemic state. Three out of four patients also had an early mutation event in a known oncogene (MED12, STAT5B or NOTCH1). Intermediate events included loss of 9p and appearance of fusion genes, while alterations in NOTCH1 were usually late events. Analysis of 185 single $CD34^+CD38^-$ HSPCs from the diagnostic and remission samples found that most early mutations were detected in HSPCs at diagnosis and remained detectable at remission, further confirming the pre-leukemic nature of these variants. Interestingly, 2 of 4 T-ALL cases had HSPCs at diagnosis in which all mutations could be detected, indicating that the accumulation of mutations can occur in progenitor cells or in committed T-cells. During remission, we could no longer detect HSPCs with all leukemic mutations.
Summary/Conclusions: We demonstrate that T-ALL patients have limited heterogeneity at diagnosis and that targeted single cell sequencing can be used to determine the cell of origin and the order of mutation acquisition. These data also illustrate that HSPCs at remission carry a few early, pre-leukemic events, while highly mutated HSPCs are eradicated during treatment, which is in line with long term remission in T-ALL.

P152

BCL-2 INHIBITION AS NEW THERAPEUTIC OPPORTUNITY FOR RPL10 R98S MUTANT PEDIATRIC T-ALL

K. Kampen[1,*], T. Girardi[1], J. Verbeeck[1], J. Op de Beeck[1], A. Uyttebroeck[2], P. Vermeersch[3], A. Moorman[4], A. Moorman[5], C. Harrison[5], J. Meijerink[6], E. Geerdens[7], D. Cassiman[8], J. Cools[7], K. De Keersmaecker[1]
[1]Oncology, KU Leuven, LKI Leuven Cancer Institute, [2]Pediatric Oncology & Hematology, [3]Laboratory Medicine, University Hospitals Leuven, Leuven, Belgium, [4]Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle-upon-Tyne, Ashmore and Cartier Islands, [5]Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle-upon-Tyne, United Kingdom, [6]Pediatric Oncology & Hematology, Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands, [7]Center for Human Genetics, LKI - Leuven Cancer Institute, VIB Center for Cancer Biology, [8]Department of Gastroenterology-Hepatology and Metabolic Center, University Hospitals Leuven, Leuven, Belgium

Background: The ribosomal protein L10 (RPL10) R98S mutation occurs in 8% of pediatric T-cell acute lymphoblastic leukemia (T-ALL) cases. RPL10 R98S leads to a proliferation defect in lymphoid cells but its oncogenic contribution in pediatric T-ALL remains unclear. Treatment intensification and risk stratification has reduced the relapse rate of T-ALL to ~15% but further improvements will require strategies that focus on specific subtypes as RPL10 R98S; if the long-term sequalae of toxic therapy are to be avoided.
Aims: 1) Explore the oncogenic contribution of the RPL10 R98S mutation in pediatric T-ALL. 2) Define new therapeutic opportunities for RPL10 R98S defective T-ALL. 3) Identify a biomarker indicative of the RPL10 R98S mutation in T-ALL.
Methods: Quantitative label-free proteomics was used to screen for protein differences between RPL10 WT and R98S expressing Ba/F3 cells. Hits were confirmed by western blot in lineage negative (lin-) bone marrow (BM) cells extracted from RPL10 WT and R98S knock-in mice and in RPL10 WT and R98S pediatric T-ALL samples. Serial re-plating was established by plating 2000 cells/ml in Methocult. Oxidative stress and mitochondrial activity was determined by Dihydroethidium and mitotracker. Viable cell counts were determined by Annexin V exclusion. Chromatin immunoprecipitation was performed using the Imprint Ch-IP kit followed by qRT-PCR. Human pediatric T-ALL samples were transplanted into NOD-SCID/$IL2\gamma^{-/-}$(NSG) mice for *in vitro* and *in vivo* inhibitor studies.
Results: The RPL10 R98S mutation provided a cell survival advantage in Ba/F3 cells and in serial re-plating assays of lin- BM cells derived from RPL10 R98S knock-in mice. Proteomic profiling revealed metabolic reprogramming in RPL10 R98S cells through enhanced expression of peroxisomal enzymes Acox1, Acox3 and Paox. This expression facilitated peroxisomal β-oxidation of long chain fatty acids which are substrates for PPARγ and which were consequently upregulated together with CPT1A. Peroxisomal hyperactivation causes high intracellular H_2O_2 levels, explaining the observed elevated levels of reactive oxygen species (ROS) in RPL10 R98S cells that could not be scavenged by the increased catalase expression. High ROS levels and enhanced PPARγ binding drives the constitutive overexpression of anti-apoptotic protein B-cell lymphoma 2 (Bcl-2), responsible for the leukemia cell survival benefit of RPL10 R98S cells. Bcl-2 targeted therapy using venetoclax (ABT-199) reduced the expansion of RPL10 R98S knock-in BM cells by 50%, while RPL10 WT BM cells were not inhibited by ABT-199. *In vivo,* DMSO or ABT-199 50mg/kg therapy was started after the engraftment of >2% human cells in the blood of mice xenografted with T-ALL samples and was maintained 1/wk till disease end stage. RPL10 R98S xenografted mice that received ABT-199 therapy presented a complete inhibition of human CD45+ leukemia progression in the blood, which was characterized by a 70-85% reduction in spleen weights, and 20-50% reduction of bone marrow engraftment. Spleen weights of ABT-199 treated RPL10 R98S xenografted mice were only slightly increased as compared to spleen weights of healthy NSG mice. In contrast, mice xenografted with RPL10 WT T-ALL samples showed poor *in vivo* responses to ABT-199 treatment and all animals showed progressive disease. Bcl-2 overexpression induced by peroxisomal hyperactivation was defined as new target in RPL10 R98S defective T-ALL. Additionally, due to peroxisomal hyperactivation, a peroxisomal oxidase involved in purine degradation may have contributed to the observation that the waste product of purine degradation, uric acid, was elevated above reference levels in the blood of RPL10 R98S mutant pediatric T-ALL patients at diagnosis (Figure 1).

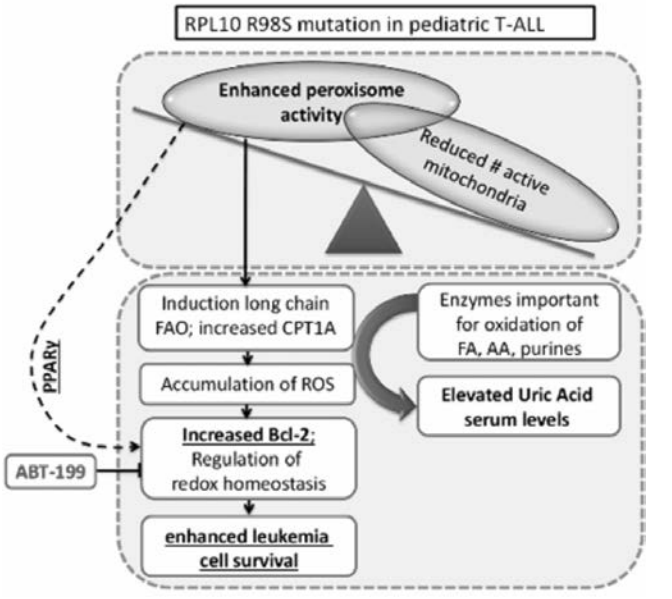

Figure 1.

Summary/Conclusions: Uric acid provides an indicative biomarker of RPL10 R98S mutations in pediatric T-ALL patients, which may be used for screening, providing early diagnosis and appropriate selection of patients in whom a Bcl-2 targeted therapeutic approach could be considered.

P153

TRANSLATOME ANALYSIS OF THE T-ALL ASSOCIATED RIBOSOMAL PROTEIN L10 R98S MUTATION REVEALS ALTERED SERINE METABOLISM

L. Fancello[1,*], K. Kampen[1], T. Girardi[1], J. Op de Beeck[1], J. Verbeeck[1], P. Vermeersch[2], D. Cassiman[3], F. Loayza Puch[4], R. Agami[4], K. de Keersmaecker[1]
[1]Department of Oncology, KU Leuven - University of Leuven, [2]Department of Laboratory Medicine, [3]Department of Gastroenterology-Hepatology and Metabolic Center, University Hospitals Leuven, Leuven, Belgium, [4]Division of Biological Stress Response, The Netherlands Cancer Institute, Amsterdam, Netherlands

Background: We previously described a recurrent arginine-to-serine mutation on residue 98 (R98S) in ribosomal protein L10 (RPL10), with a frequency of 8.6% in pediatric T-ALL cases. The R98 mutated residue contacts the catalytic core (peptidyltransferase center, PTC) of the ribosome and causes ribosome biogenesis and translational fidelity defects in yeast and lymphoid cells. These observations suggest that the RPL10-R98S mutation may contribute to T-ALL pathogenesis by inducing translational changes.
Aims: The spectrum of translated proteins (translatome) of RPL10 R98S mutants was investigated in order to identify translational changes caused by the mutation and potentially driving oncogenesis.
Methods: We performed ribosome footprinting (RNA sequencing of ribosome bound RNA), polysomal RNA sequencing, total RNA sequencing and mass spectrometry based quantitative proteomics on engineered RPL10-R98S or RPL10-WT mouse lymphoid Ba/F3 cells.
Results: RPL10 R98S cells showed significant upregulation for 3% (n=178) of the measured proteins and a downregulation of 1% (n=68). Moreover, polysomal RNA sequencing and ribosome footprinting showed respectively 57 and 22 genes with significantly higher translational efficiency in RPL10 R98S, and 22 and 29 genes, with reduced translational efficiency. Among them, we also found genes involved in T cell differentiation and proliferation. In particular, Mapk6 presented reduced translational efficiency in the ribosome footprinting, potentially due to differences in ribosome occupancy of an upstream ORF, whereas the transcription factor Ikzf2, a master regulator of the upregulated transcripts, was overexpressed at the transcriptional and protein level. Interestingly, the results from the mass spectrometry and the polysomal RNA sequencing datasets showed a significant enrichment and upregulation of members of the JAK-STAT signaling pathway with Csf2rb/2, Jak1 and several Stats being 1-3-fold elevated at the protein level and higher translation efficiency for Lif, Socs1, Pim1, Osm, Il10ra, Cish and Il21r. Another interesting candidate showing 5-fold upregulated protein levels was phosphoserine phosphatase (Psph), a key enzyme in serine biosynthesis. Ribosome footprinting revealed that this upregulation originates from a combination of higher transcription and translational efficiency of the encoding gene. Elevated Psph protein levels were confirmed by immunoblots in the RPL10 R98S Ba/F3 cells and in hematopoietic cell cultures derived from Rpl10 R98S knock-in mice. Interestingly, exhausted medium from RPL10 R98S Ba/F3 cells contained higher residual serine levels as compared to RPL10 wild type expressing cells and this medium could support the survival of wild type Ba/F3 cells. Our data suggest that RPL10 R98S expressing cells enhance their endogenous serine production, leaving more serine that can support survival of neighboring cells.
Summary/Conclusions: Analysis of the translational changes associated with the RPL10 R98S mutation reveals alterations for genes involved T cell differentiation and proliferation: the atypical MAP kinase Mapk6, whose reduced translational efficiency still needs to be validated at the protein level, and the transcription factor Ikzf2. Alterations were also found in the JAK-STAT signaling, an established oncogenic cascade in T-ALL. Moreover, this is the first description of a mutation in T-ALL that is linked to alterations in cellular serine biosynthesis.

REPOSITIONING EXISTING DRUGS AS NOVEL THERAPEUTICS: OXIDATIVE STRESS AS A TARGET FOR HIGH-RISK LEUKAEMIA IN CHILDREN

M. Karsa[1,*], K. Somers[1], A. Mariana[1,2], T. Failes[1,2], G. M. Arndt[1,2], U. R. Kees[3], M. Haber[1], M. D. Norris[1], R. Sutton[1], R. B. Lock[1], M. J. Henderson[1]
[1]Children's Cancer Institute, Lowy Cancer Research Centre, University of New South Wales, [2]ACRF Drug Discovery Centre for Childhood Cancer, Children's Cancer Institute, Lowy Cancer Research Centre, University of New South Wales, Sydney, New South Wales, [3]Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia

Background: Remarkable improvements made in the treatment of childhood acute lymphoblastic leukaemia (ALL) in past decades have resulted in 5-year survival rates approaching 90%. However, prognosis remains dismal for certain subgroups of high-risk patients, including poor responders to induction therapy, infants with ALL that harbor rearrangement of the *Mixed Lineage Leukaemia* (*MLL/KMT2A*) gene, and children with Philadelphia chromosome positive ALL. In particular, infant ALL patients with *MLL* disease have survival rates below 50% despite the use of intensified treatments, necessitating the development of more effective, less toxic therapeutics for them.
Aims: The aim of this study is to identify candidates that target *MLL*-rearranged leukaemia cells using drug-repurposing, whereby an approved drug is applied to treat a disease other than the one for which it was originally intended. This drug discovery strategy is gaining popularity as it potentially avoids the lengthy process of drug development and FDA approval.
Methods: 3707 approved drugs and pharmacologically active compounds were initially screened against an infant ALL cell line with *MLL*-rearrangement, PER-485 and a paediatric leukaemia cell line wild-type for *MLL*, CEM, using a resazurin-based cell viability assay. Hit compounds were further tested in a panel of 16 leukaemia cell lines, seven solid tumour lines and two normal cell lines. Compounds were subsequently evaluated *in vitro* for cytotoxic activity against a panel of 20 paediatric high-risk ALL patient-derived xenograft (PDX) cells. Apoptosis was measured by Annexin V positivity and PARP cleavage. Reactive oxygen species (ROS) levels were assessed by DCF-DA staining and detection by flow cytometry. Nrf2 protein expression levels were measured by Western blotting.
Results: The screen resulted in the identification of two FDA-approved drugs that were preferentially cytotoxic against *MLL*-rearranged ALL and other leukaemia cell lines, compared to solid tumours and normal cells. Auranofin was originally developed for rheumatoid arthritis and was later fast-tracked into Phase II clinical trial for adult chronic lymphocytic leukaemia, while Disulfiram, which was developed for treatment of chronic alcoholism, is currently in several clinical trials for cancers including metastatic melanoma and glioblastoma. These drugs also showed potent activity in high-risk paediatric leukaemia PDX cells cultured *in vitro*, including *MLL*-rearranged ALL and Philadelphia-positive ALL with IC_{50} values between 100-400 nM for Auranofin and 30-60 nM for Disulfiram. Induction of apoptosis was evident at 6 hours post Auranofin treatment, or after 12 hours Disulfiram treatment. Each drug significantly increased intracellular ROS as early as one hour post-treatment ($p<0.01$), which was accompanied by induction of Nrf2, a master regulator of the antioxidant response. Incubation with ROS scavenger N-acetyl cysteine prior to treatment with either drug prevented the increase in cellular ROS levels ($p<0.05$) and rescued cells from apoptosis ($p<0.0001$), indicating involvement of reduction-oxidation and increased ROS generation as mechanisms of leukaemia cell death induced by these drugs.
Summary/Conclusions: In summary, we have identified two FDA-approved drugs that demonstrated potent anti-leukaemia activity through induction of ROS, potentially opening up new avenues for clinical treatment of high-risk paediatric leukaemia. We will now be testing these potential therapies *in vivo* using relevant PDX models of high-risk paediatric ALL.

P155

TP53 MUTATIONS DISRUPTING DNA BINDING LEAD TO CHEMOTHERAPY RESISTANCE IN ACUTE LYMPHOBLASTIC LEUKEMIA

M. Pogodzinski[1,*], F. Yang[2,3], H. Sun[3], J. Hof[1], C. Eckert[1], B.-B. Zhou[3], R. Kirschner-Schwabe[1]
[1]Pediatric Oncology and Hematology, Charité - Universitaetsmedizin Berlin, Berlin, Germany, [2]College of Life Sciences, Beijing Normal Universitiy, Beijing, [3]Oncology and Hematology, Shanghai Childrens Medical Center, Shanghai, China

Background: Polychemotherapy resistance is a major challenge in the treatment of children with relapsed acute lymphoblastic leukemia (ALL). Mutation of *TP53* is tightly associated with poor response to treatment in ALL relapse patients.
Aims: We studied mutations of *TP53* in ALL relapses and in six ALL cell lines to shed light on mechanisms and pathways mediating *TP53* dependent drug resistance in relapsed ALL. First, we analyzed the spectrum of *TP53* mutations in ALL relapses and correlated it to treatment response of patients. Second, we studied drug sensitivity in *TP53* wild type (wt) *versus TP53* mutant ALL cell lines.
Methods: *TP53* was sequenced by the method of Sanger. Drug sensitivity was determined by IC50 in ALL cell lines. Drugs included in the study were DNA damage inducing agents as topoisomerase II inhibitors, alkylating agents, nucleotide analoga, and other agents, most of which are used in ALL relapse treatment protocols.
Results: We identified 20 different *TP53* mutations in 34 patients. We classified *TP53* mutations into 'hot spot' (R175, G245, R248, R273 and R282), non-hot spot and frameshift, respectively. We found that hot spot *TP53* mutations were enriched in ALL relapse patients with non-response to treatment compared to good responding patients (64 *versus* 27%). In ALL cell lines, we confirmed *TP53* mutations in Jurkat (R196*) and Loucy (V272M) and identified R248P in MHH. Three ALL cell lines were *TP53* wt (SUP-B15, UOC-B6, NALM-6) and used as controls. Topoisomerase II inhibitors upregulated expression of wt p53. In contrast, nucleotide analoga showed no p53 induc-

tion. IC50 measurements showed that *TP53* mutations lead to resistance against topoisomerase II inhibitors and alkylating agents, but not against other drugs. The upstream pathway of p53 (CHK1, CHK2) and DNA damage recognition (γH2AX) were not impaired in the six ALL cell lines. To study the effect of *TP53* mutation on resistance to treatment in more detail, we focused on the R248P mutation, located in hot spot codon 248, that we found in a relapse patient with non-response to treatment and in the MHH cell line. Using a CRISPR/Cas9 knockout (KO) of endogenous p53 and lentiviral based re-expression in NALM-6, we generated p53 KO, and KO+wt p53, KO+R248P and KO+GFP cell lines. The KO cells showed a similar resistance to DNA damage inducing drugs as KO+R248P cells. Overexpression of wt p53 in KO cells restored the sensitivity to DNA damage inducing drugs. In contrast to wt p53, R248 did not inhibit cell proliferation under drug treatment. We found that this mutant was unable to induce downstream targets of p53 (p21, BAX). Moreover, ChIP-seq showed that R248P cannot bind the promotor and induce expression of typical p53 targets MDM2, p21, BAX, BCC3/PUMA, FAS or RRM2B/p53R2. This result indicates that R248P is deficient in binding the consensus element of p53. However, the binding motif analysis showed that the R248P mutant still binds DNA at a different and purine-rich sequence. In summary, R248P leads to loss of wt p53 function and mediates resistance to topoisomerase II inhibitors and alkylating agents.

Summary/Conclusions: Overall, our results show that mutations affecting *TP53* hot spots, in particular codon 248, are associated with resistance of ALL cells to chemotherapy and reveal first insights into underlying mechanisms and pathways.

P156

GENETIC ACTIVATION AND THERAPEUTIC TARGETING OF PIM1 IN T-CELL ACUTE LYMPHOBLASTIC LYMPHOMA

Background: T-cell acute lymphoblastic leukemia (T-ALL) and T-cell acute lymphoblastic lymphoma (T-LBL) are aggressive immature T-cell malignancies that are considered one disease entity according to the World Health Organization (WHO). Both T-ALL and T-LBL are often characterized by improper T-cell receptor (TCR) recombinations leading to aberrant activation of proto-oncogenes.

Aims: Despite some genetic and phenotypic similarities between T-ALL and T-LBL, T-ALL risk group stratification cannot be extrapolated to T-LBL patients. Therefore, it is our goal to find new T-LBL markers and develop new targeted therapies based on those T-LBL specific markers.

Methods: Here, we used Targeted Locus Amplification (TLA, de Vree *et al.*, *Nat Biotechnol, 2014*) to identify a novel translocation (leading to PIM1 kinase overexpression) in a human T-LBL patient. Unraveling the importance of PIM1 activation in T-LBL disease biology prompted us to do both RNA sequencing and phosphoproteomic studies to identify its downstream targets. T-LBL patient engraftment in NSG mice enabled us to study the therapeutic potential of PIM1 inhibition.

Results: Applying the TLA technique lead to the identification of a novel TCRβ driven t(6;7)(p21;q34) translocation in a human T-LBL patient resulting in aberrant activation of the PIM1 proto-oncogene. PIM1 is a constitutively active serine/threonine kinase involved in cell cycle progression, apoptosis, transcription and drug resistance and is overexpressed in a variety of human cancers. Further characterization of this *PIM1* rearranged patient sample revealed cooperative genetic alterations that target known T-ALL/T-LBL onco- and tumor suppressor genes, including NOTCH1, IKZF1, EP300 and CDKN2A. Comparing *PIM1* expression between normal T-cell subsets, T-ALL and T-LBL patient samples showed that T-LBL patients express significantly higher *PIM1* levels, confirming PIM1 activation is implicated in T-LBL disease biology. Next, we looked at allelic expression ratios of PIM1 and interestingly, we found skewed allelic expression in T-LBL, but not in T-ALL patients. To study the oncogenic properties of PIM1 in the context of malignant T-cell transformation, we did RNA sequencing and phosphoproteomics on the T-ALL/T-LBL tumor line HSB-2 (high PIM1) after PIM inhibition with TP-3654 (Foulks *et al.*, *Neoplasia*, 2014). These data revealed that PIM1 inhibition has broad effects on transcription and phosphorylation substrates involved in cell cycle, translation and apoptosis. Finally, we evaluated the therapeutic potential of PIM1 inhibition. Daily TP-3654 treatment (4 weeks) of T-LBL engrafted NSG mice resulted in strong anti-leukemic effects. Currently, we are evaluating if combination of PIM1 inhibition with chemotherapeutics triggers a more profound anti-leukemic response (Figure 1).

Summary/Conclusions: All together, our study identifies PIM1 as a putative oncogene in T-LBL and suggests that inhibition of this serine/threonine kinase could serve as a novel therapeutic strategy in this aggressive T-cell neoplasm.

IL-7 FLEXIBLY REGULATES AUTOPHAGY-DEPENDENT VIABILITY OF T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA CELLS

D. Ribeiro[1,*], I. Lopes[1], C. Custódia[1], J. Silva[1], M. Abreu[1], J. Barata[1]

[1]JBarata Lab, Instituto de Medicina Molecular, Lisbon, Portugal

Background: T-cell acute lymphoblastic leukemia (T-ALL) constitutes an aggressive subset of ALL, the most frequent childhood malignancy. T-ALL cases are high risk and a significant fraction of the patients still relapse despite intensive chemotherapy, prompting the need for a deeper understanding of T-ALL biology in order to develop novel therapies. Autophagy is a homeostatic intracellular process characterized by the sequestration of cytoplasmic compartments within double-membrane vesicles (autophagosomes) to promote their degradation. Importantly, autophagy is upregulated during starvation, cellular stress or in rapidly dividing cells, such as cancer cells, as a compensatory mechanism to provide nutrients and stress relief. By mitigating stress and allowing cell survival, autophagy may serve as a pro-tumoral mechanism. On the other hand, persistent autophagy can lead to cell death and thereby prevent tumor growth. Interleukin-7 (IL-7) is essential for normal T-cell development but there is considerable evidence that IL-7-mediated signaling can also contribute to leukemogenesis. A majority of T-ALL patients expresses the IL-7 receptor and IL-7 accelerates T-ALL disease progression *in vivo* and promotes T-ALL cell proliferation, survival and metabolic activation *in vitro* via PI3K/Akt/mTOR pathway (a master negative regulator of autophagy). IL-7 can also activate MEK/Erk pathway (which has been implicated in promotion of autophagy).

Aims: Since IL-7 has the ability to activate signaling pathways with potentially opposing roles in autophagy regulation, our goal was to explore the actual impact of IL-7 on the autophagic process in T-ALL cells and elucidate its molecular mechanisms and functional consequences.

Methods: We used an IL-7-dependent leukemia T-cell line (TAIL7) and "primary" cells from patient-derived xenografts (PDX). We used inhibitors of PI3K (LY294002), mTOR (rapamycin), MEK1/2 (UO126) and ULK1/2 (MRT68921). Analysis of viability and cell size was performed by flow cytometry. Signaling pathway activation and LC3-I/-II conversion was performed by western blot analysis. LC3 puncta formation was assessed by confocal microscopy. Autophagosome/autolysosome formation was analyzed by electron microscopy.

Results: We show that in optimal culture conditions (medium with serum) IL-7 *inhibits* autophagy in T-ALL, albeit in a complex manner that involves triggering both pro- (via MEK/Erk) and anti- (via PI3K/Akt/mTOR) autophagic signaling. In this scenario, IL-7-mediated viability relies on the latter pathway, as we previously described. In contrast, under stress conditions (serum starvation) IL-7 *promotes* autophagy in leukemia cells. In this situation, IL-7-mediated survival partially relies on autophagy activation and strictly requires MEK/Erk activation. Mechanistically, we provide evidence that depending on culture conditions, IL-7 can balance the relative activation of PI3K/Akt/mTOR and MEK/Erk pathways towards or against autophagy in order to consistently promote T-ALL cell viability.

Summary/Conclusions: Our results suggest that IL-7 makes use of a 'flexible strategy' to promote T-ALL cell viability by recruiting both pro- and anti-autophagic pathways, which are differentially recruited to prevent tumor cell death depending on the microenvironmental conditions. Our data strengthen the notion that combination therapies against PI3K/Akt/mTOR and MEK/Erk pathways may be of particular relevance in the context of T-ALL.

P158

PRECLINICAL ACTIVITY OF ENTOSPLETINIB IN CHILDHOOD B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

A. Yahiaoui[1], J. P. Loftus[2], M. Axelrod[1], A. Forslund[1], S. Tannheimer[1], S.K. Tasian[2,3,*]

[1]Biomarker Sciences, Gilead Sciences, Inc., Foster City, [2]Division of Oncology

and Center for Childhood Cancer Research, Children's Hospital of Philadelphia, [3]Pediatrics, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, United States

Background: B-cell acute lymphoblastic leukemia (B-ALL) is the most common malignancy of childhood and is highly curable with modern risk-adapted chemotherapy. However, 15-20% of children and >60% of adults with B-ALL develop chemoresistance and relapse, indicating need for new therapies. Addition of kinase inhibitors to chemotherapy for patients with *BCR-ABL1*-rearranged (Ph+) B-ALL has dramatically improved event-free and overall survival, and similar approaches are now under active clinical investigation in patients with *BCR-ABL1*-like (Philadelphia chromosome-like or Ph-like) B-ALL. Recent studies have demonstrated activated spleen tyrosine kinase (SYK) signaling in various genetic subtypes of B-ALL and preclinical activity of the SYK/FLT3/JAK inhibitor fostamatinib. However, SYK activation in B-ALL and potential correlation with specific leukemia-associated mutations remains incompletely characterized. We hypothesized that constitutive activation of SYK signaling occurs across a genetic spectrum of infant and high-risk childhood B-ALL and can be therapeutically targeted *in vivo* with the selective SYK inhibitor entospletinib (ento).
Aims: (1) Assess basal SYK signaling activation in childhood B-ALL specimens. (2) Quantify treatment efficacy, pharmacokinetics (PK), and pharmacodynamic (PD) effects of ento in childhood B-ALL patient-derived xenograft (PDX) models.
Methods: Total and phosphorylated (p) SYK levels were assessed by Simple Western analysis of splenic lysates from NSG mice well-engrafted with primary pediatric B-ALL specimens (n=19 Ph-like, n=4 infant *KMT2A*-rearranged (R), and n=4 infant non-*KMT2A*-R PDX models) to identify leukemias with constitutive SYK signaling activation. To assess *in vivo* activity of SYK inhibition, selected B-ALL PDX models with high basal pSYK (n=2) were treated with continuously provided control, ento 0.03%, or ento 0.07% chow. Cohorts of mice were sacrificed after 21-28 days, and peripheral blood and spleens were harvested for downstream studies. Flow cytometric analyses of murine tissues were performed to assess initial human ALL engraftment and to measure ento treatment responses. PK and PD assessments were performed in terminal peripheral blood and spleens, respectively.
Results: Constitutive pSYK signaling was observed in 10/19 Ph-like, 4/4 *KMT2A*-R, and 1/4 non-*KMT2A*-R B-ALL specimens. Ento treatment of *KMT2A-MLLT3* (ALL3103) and Ph-like *NUP214-ABL1* (NH011) PDX models significantly inhibited ALL proliferation *in vivo versus* control animals at both 0.03% and 0.07% chow formulations (representative data in Figure 1; $p<0.05$). Steady state concentrations were maintained throughout the study duration with terminal PK values of 3.3 (± 0.5) and 7.9 (± 1.0) μM (0.03% and 0.07% ento arms, respectively). PD studies demonstrated dose-dependent *in vivo* inhibition of pERK measured in human leukemia cells within spleens of ento-treated mice without alterations in total SYK protein levels. In general, PD inhibition of SYK target phosphoproteins was more pronounced in 0.07% ento-treated animals.

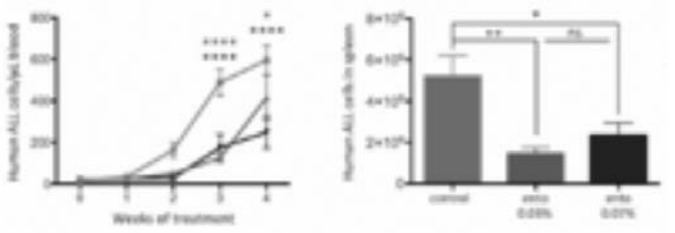

Figure 1.

Summary/Conclusions: Constitutive activation of SYK signaling occurs frequently in childhood Ph-like and infant *KMT2A*-R childhood B-ALL. Ento treatment of B-ALL PDX models potently inhibited SYK pathway signaling proteins and significantly inhibited leukemia proliferation *in vivo*.

P159

PHARMACOLOGICAL ACTIVITY OF CB-103 – AN ORAL PAN-NOTCH INHIBITOR WITH A NOVEL MODE OF ACTION

R. Lehal[1,*], D. Weber[1], V. Frismantas[2], J.-P. Bourquin[2], M. Bauer[1], M. Murone[1], F. Radtke[3]
[1]Cellestia Biotech AG, Basel, [2]University Children`s Hospital, Zürich, [3]Swiss Institute for Experimental Cancer Research, EPFL, Lausanne, Switzerland

Background: NOTCH signalling is a developmental pathway known to play critical roles during embryonic development as well as for the regulation of self-renewing tissues. Aberrant activation of NOTCH signalling leads to deregulation of the self-renewal process resulting in sustained proliferation, evasion of cell death, loss of differentiation capacity, invasion and metastasis, all of which are hallmarks of cancer. When the NOTCH pathway is inappropriately activated by genetic lesions (over expression of NOTCH ligands/receptors, GOF mutations in NOTCH receptors as well as chromosomal translocations), it becomes a major driver for NOTCH-dependent cancers and resistance to standard of care treatment. Over 250´000 patients are annually diagnosed with NOTCH dependent cancers, with no specific therapy available to date.
Aims: Given the importance of NOTCH signalling in human cancers, several therapeutic approaches have been utilized to block NOTCH signalling. Two of these strategies are; a) the use of monoclonal blocking antibodies (mAbs) against NOTCH ligands and receptors and b) the use of small molecule gamma-secretase inhibitors (GSIs). However, these approaches can only be effective if tumor cells express full-length ligand or receptor molecules. As validation of NOTCH as a therapeutic target, clinical activity of these in clinical studies were was observed in various trials for some of these inhibitors (mAbs, GSIs), but treatment and exposure were usually limited due to toxicities, mainly related to gastro-intestinal adverse events. On the contrary, in human cancers harbouring NOTCH gene fusion due to chromosomal translocations or specific NOTCH mutations, the use of mAbs and GSIs will have very limited clinical benefits. Cellestia has decided to follow a disruptive approach, by blocking NOTCH signalling in the most downstream part of the NOTCH cascade, at the level of the NOTCH transcriptional activation complex, using small molecule inhibitors.
Methods: Here we report the pharmacological characterization of CB-103, a first-in-class orally-active small molecule inhibitor of the NOTCH transcriptional activation complex.
Results: We demonstrate that *in vitro* CB-103 potently inhibits NOTCH signalling in various leukemic and lymphoma cell lines, and T-ALL blasts derived from relapse/refractory patients. In addition, CB-103 exhibited anti-tumor efficacy in multiple *in vivo* models of NOTCH-driven T-ALL using T-ALL cell lines and patients derived xenograft models.
Summary/Conclusions: Toxicology studies have been completed and clinical development of CB-103 with a first-in-human Phase I/IIA clinical study in advanced solid tumors and haematological malignancies is under preparation.

Acute lymphoblastic leukemia - Clinical 1

P160

IKZF1Δ4-7 CAN BE EASILY SCREENED BY PCR BUT DOES NOT PREDICT OUTCOME IN ADULTS WITH ACUTE LYMPHOBLASTIC LEUKAEMIA; DATA FROM 490 PATIENTS ENROLLED ON THE UKALL14 TRIAL

R.J. Mitchell[1,*], A.A. Kirkwood[2], B. Wrench[3], A. Fearn[4], C. Schwab[4], E. Lawrie[2], K. Zuborne Alapi[1], L. Clifton-Hadley[2], P. Patrick[2], T. Naughton[1], A.V. Moorman[4], A.K. Fielding[1]
[1]UCL Cancer Institute, [2]CRUK and UCL Cancer Trial Centre, UCL, [3]Barts Cancer Institute, QMUL, London, [4]Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle Upon Tyne, United Kingdom

Background: The *IKZF1* gene encodes the IKAROS zinc finger transcription factor and master regulator of lymphocyte differentiation. *IKZF1* lesions are common in acute lymphoblastic leukaemia (ALL) and have been reported as independent prognostic factors for poor outcome. *IKZF1*Δ4-7, resulting in the dominant negative *IK6* isoform is the most common single *IKZF1* deletion.
Aims: We aimed to generate and validate a simple, PCR-based screening assay for *IKZF1*Δ4-7 and to determine its utility as a prognostic marker in B precursor ALL using data from UKALL14 (ISRCTN 66541317)- a multicentre phase 3 randomised trial for adults aged 25-65 years.
Methods: Diagnostic DNA from 490 bone marrow samples was screened for *IKZF1*Δ4-7 using an endpoint PCR assay using primers located in introns 3 and 7. The lower limit of detection was determined by serial dilution of DNA from the *IK6*-expressing cell line SUP-B15 and calculated to be 0.001%. A total of 95 samples were also tested using the MLPA P335 kit to detect the full spectrum of IKZF1 deletion. Sanger sequencing confirmed the breakpoints in 27 cases.
Results: The median age of the patients tested was 46 years (range 25-65). Overall *IKZF1*Δ4-7 was detected in 97/490 (20%) patients but the frequency varied by genetic subtype. Patients with *BCR-ABL1* fusion had the highest *IKZF1*Δ4-7 frequency (46/150, 31%) followed by patients with B-other ALL (29/154, 19%). Patients with other classic cytogenetic abnormalities harboured significantly fewer *IKZF1*Δ4-7 – low hypodiploidy (3/26), *MLL* gene fusions (3/31), t(1;19), (1/11), high hyperdiploidy (2/9) and iAMP21 (0/3). MLPA did not detect any *IKZF1*Δ4-7 deletions that were not detected by PCR but did identify several samples with alternative *IKZF1* deletions affecting different exons (see Table 1). By contrast, the PCR assay did detect six *IKZF1*Δ4-7 deletions undetected by MLPA, consistent with the higher sensitivity of this approach. Interestingly, three of these samples harboured alternative *IKZF1* deletions in addition to *IKZF1*Δ4-7. In 70 (14%) cases, we observed a "faint" PCR band. Since the biological relevance of this was not clear, the 'faint' bands were not included in the main analysis. Interestingly the frequency of these "faint" bands was similar across all genetic subtypes: *BCR-ABL1* (14%), B-other (15%), MLL (21%), low hypodiploidy (19%). We examined the impact of *IKZF1*Δ4-7 on achievement of CR, persistence of minimal residual disease (MRD) at >1 x 10^{-4} (Ig/TCR quantitation by EuroMRD criteria) after courses 1 and 2 of therapy, EFS, OS and time to relapse, at a median follow-up of 23.1 months. Two thirds of patients (44/66) with *IKZF1*Δ4-7 were MRD positive at the end of phase 1 compared with 147/273 (54%) patients without the deletion (p=0.059). However, this relationship between *IKZF1*Δ4-7 and MRD did not persist after phase 2. We did not identify any association between *IKZF1*Δ4-7 and any of the other outcome parameters tested.

Table 1.

PCR	MLPA	Concordance	Total
Neg	Neg	56 concordant	73
	Del Ex 1-8 N=1 Del Ex 2-7 N=3 Del Ex 2-8 N=2 Del Ex 4-8 N=3 Del Whole gene N=6	15 'expectedly' discordant due to del >exons 4-7	
	Failed	2 concordance not assessable	
Pos	Pos	12 concordant	22
	Failed	4 concordance not assessable	
	Del exons 2-3, N=1 Del whole gene N=2	3 discordant probably due detection limit of 20% for MLPA	
	No deletion detected	3 discordant – probably due detection limit of 20% for MLPA	

Summary/Conclusions: *IKZF1*Δ4-7 can be detected by a simple and cheap PCR assay, which is more sensitive than MLPA. The frequency of *IKZF1*Δ4-7 was broadly comparable with previous studies. However, we did not find an association between *IKZF1*Δ4-7 and clinical outcome in this large clinical trial sample set. We are in the process of evaluating the impact of other *IKZF1* lesions.

P161

PROGNOSTIC SIGNIFICANCE OF MINIMAL RESIDUAL DISEASE DETECTED BY MLL FUSION GENE TRANSCRIPTS IN INFANT ACUTE LYMPHOBLASTIC LEUKEMIA. UPDATED RESULTS OF 76 PATIENTS ENROLLED INTO MLL-BABY STUDY

G. Tsaur[1,*], A. Popov[2], T. Riger[1], A. Solodovnikov[1], A. Kustanovich[3], O. Aleinikova[3], Y. Olshanskaya[2], N. Myakova[2], T. Verzhbitskaya[1], E. Shorikov[4], O. Streneva[1], O. Arakaev[1], A. Vlasova[1], S. Tsvirenko[5], L. Saveliev[5], L. Fechina[1]
[1]Regional Children Hospital #1, Research Institute of Medical Cell Technologies, Ekaterinburg, [2]National Research Institute of Pediatric Hematology, Oncology, and Immunology named after Dmitriy Rogachev, Moscow, Russian Federation, [3]Belarusian Research Center for Pediatric Oncology, Hematology and Immunology, Minsk, Belarus, [4]PET Technology, [5]Ural State Medical University, Ekaterinburg, Russian Federation

Background: Fusion gene transcripts (FGTs) are rarely used for minimal residual disease (MRD) monitoring in acute lymphoblastic leukemia (ALL) cases, except of Ph-positive ALL. However in infant ALL, where *MLL* gene rearrangements are found the majority of cases, *MLL* FGTs are attractive targets for MRD detection.
Aims: To estimate prognostic significance of MRD by qualitative detection of different *MLL* FGTs in infant ALL treated by MLL-Baby protocol.
Methods: Seventy six infants (27 boys and 49 girls) with median age of 5.8 months (range 0.03-11.83) were included in the current study. Among them there were 39 (51.3%) *MLL-AF4*-positive cases, 14 (18.4%) *MLL-MLLT1*-positive, 12 (15.8%) *MLL-MLLT3*-positive, 6 (7.9%) *MLL-MLLT10*-positive, 4 (5.3%) *MLL-EPS15*-positive ones. MRD detection was performed in BM samples by real-time quantitative PCR and nested RT-PCR with sensitivity non-less than 1E-04. MRD-negativity was defined as absence of FGTs in the both assays. Median of follow-up period in the observed group was 6.4 years. Informed consent was obtained in all cases.
Results: We confirmed our earlier finding that the most informative TP for the MRD detection was TP4 (G. Tsaur at al, EHA 2012 abs O1096). MRD-positivity at TP4 led to unfavorable outcome in both *MLL-AF4*-positive patients stratified to high-risk arm of MLL-Baby protocol (EFS 0.05±0.04 *vs* 0.78±0.07 p<0.0001; cumulative incidence of relapse 0.78±0.10 *vs* 0.11±0.07 p<0.0001, respectively) and for all others *MLL*-rearranged patients treated by intermediate risk (ImR) arm (EFS 0.00 *vs* 0.71±0.11 p<0.0001; cumulative incidence of relapse 1.0 *vs* 0.29±0.10 p<0.0001, respectively). There were no significant differences in initial patients' characteristics and treatment response criteria (on days 8, 15, 36) among 38 MRD-positive and 38 MRD-negative patients. Multivariate analysis revealed that initial CNS disease (hazard ratio (HR) 2.703, 95% CI 1.255-5.284, p=0.011), non-M1 status of BM on day 15 (HR 3.090, 95% CI 1.465-6.515, p=0.003) and MRD-positivity at TP4 (HR 6.950 95% CI 2.617-18.456) were significant covariates with negative impact on hazard of unfavorable event. Based on dismal outcome of MRD-positive ImR patients we tried to augment their therapy and relocated 5 of them from ImR group to HR arm after TP4. Although all of them subsequently relapsed. We also wanted to find out which characteristics might predict relapse in ImR patients who were MRD-negative at TP4 (n=5). Of note, all these 5 relapsed patients (100%) had initial CNS disease while CNS disease was detected only in 2 out of 19 ImR patients (10.5%) who stayed in complete hematological and molecular remission (p=0.003). Also all 5 relapsed ImR patients who were MRD-negative at TP4 had breakpoint positions within intron 11 of *MLL* gene and they were MRD-positive by flow cytometry (MRD ≥0.01%) on day 15. None of MRD-negative patients by flow cytometry (MRD <0.01%) on day 15 relapsed later on (p<0.001).
Summary/Conclusions: MRD monitoring by detection of *MLL* FGTs was feasible and had significant prognostic impact. MRD-positivity at TP4 was an independent factor of unfavorable outcome in infants with *MLL*-rearranged ALL enrolled into MLL-Baby protocol irrespective of treatment arm. Treatment intensification for MRD-positive at TP4 ImR patients did not improve their outcome. MRD-positivity at TP4 in ImR group was associated with MRD-positivity by flow cytometry on day 15, *MLL* breakpoint positions within intron 11 gene and initial CNS disease.

P162

PRO-T CELL ALL/LBL: AN ULTRA-HIGH RISK CD2-NEGATIVE DISEASE SUBTYPE IN ADULTS DEFINED BY FLOW CYTOMETRY

B. Ostrowska[1,*], G. Rymkiewicz[2], K. Domanska-Czyz[1], J. Romejko-Jarosinska[1], K. Blachnio[2], L. Poplawska[1], W. Michalski[3], J. Walewski[1]
[1]Department of Lymphoid Malignancies, [2]Department of Pathology and Laboratory Diagnostics, [3]Department of Biostatistics, The Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland, Warszawa, Poland

Background: Risk fators for T-LBL have not been systematically evaluated, in contrast to T-ALL
Aims: Our aim was to define immunophenotype of T-LBL/ALL in 71 consecutive patients by use of the flow cytometry (FCM) of tissue aspirates if peripheral blood (PB) and bone marrow (BM) were uninvolved. We also evaluated prognostic value of immunophenotype according to WHO 2008 subtype and ETP (Early T-cell Phenotype) definition in adult patients with T-ALL/LBL treated on uniform ALL protocol
Methods: Between 1997 and 2015, 71 adult patients with T-LBL/ALL were treated according to the GMALL 05/93 and T-LBL/2004 protocols. Immunophenotype was determined by immunohistochemical staining and by FCM of cellular suspension obtained from lymph nodes (n=31), mediastinal mass (n=12) or nasopharyngeal/perimandibular infiltration (n=2) by fine needle aspiration biopsy (FNAB), as well as of BM (n=10), PB (n=7) and pleural fluid (n=9). Disease subtype was defined according to WHO 2008 classification: pro-T (CD2-), pre-T (CD2+), cortical (CD1a+), medullary/mature (sCD3+). Recognition of pan-T cell CD antigens (pTAg) expression included: CD1a, CD2, sCD3, CD4, CD5, CD7, CD8. ETP-ALL/LBL immunophenotype was defined as follows: absent (up to 5%positive cells) CD1a and CD8 expression, absent or dim (75% positive cells) CD5 expression, expression(25% positive cells) of 1 or more myeloid (CD13,CD33, CD15) or stem cell (CD34, HLA-DR) markers.
Results: Patient characteristics: ALL (BM+ >20%): n=26(37%), LBL: n=45(63%), BM+<20% involvement (LBL): 27%, age<35ys: 72%, males: 67%, mediastinal mass (MM): 92%, primary CNS+: 8%.Immunophenotype: pro-T: 21%, pre-T: 17%, cortical: 55%, medullary: 7%. Number of pTAg present: 0-3: n=25(36%) or 4-7: n=45(64%) of pts. Most frequently expressed pTAg were: CD7: 97%, CD5: 87%, CD2: 74%, CD1a: 58%. Myeloid markers: CD13/33/15 were expressed in 13%/26%/10% and stem cell markers: CD34% in 42% of pts. Overall, 19% (13/67) of the study population had ETP-ALL/LBL: CD1a-/CD8-, but CD5 negative: 46% and CD5 weaker (20-71%): 54%, CD34/HLA-DR/13/33/15 expressed in 100%/50%/50%/75%/14% of ETP pts. 4 pts(31%) with ETP were categorized as pre-T and 9 pts(69%) as pro-T. With a median (95%CI) follow up of 137 (0.99, 1.733)months, 5-yr OS and DFS (95%C.I.) was 53% (0.42, 0.65) and 48% (0.36, 0.59),respectively. 5-yr OS (95%C.I.) for pts with CD2, CD1a and more than 3 pTAg present was 64% (0.511, 0.776), 66% (0.512, 0.803) and 64% (0.5, 0.782) compared to 11% (0.034, 0.256), 32% (0.152, 0.494) and 27% (0.097, 0.452) for pts without CD2, CD1a and 3 or less pTAg, (P<0.001, 0.009 and 0.002),respectively. OS and DFS was dependent on WHO subtype (p<0.001/p=0.002). 5-yr OS (95%C.I.):cortical: 69% (0.547, 0.837), pre-T 48% (0.196, 0.776),mature 40% (0.029, 0.829) and pro-T 10% (0.072, 0.272). There was no significant difference in OS and DFS in pts with ETP *vs* non-ETP (P=0.186, 0.159), 5-yr OS (95%C.I.): 31% (0.57, 0.559) and 55% (0.418, 0.685) for ETP and non-ETP pts, respectively. Among ETP pts, 4/13(31%) are alive, 3/4(75%) pts with pre-T and only 1/9((11%) with pro-T phenotype.3/7 pts were rescued with allo-HCT (Figure 1).

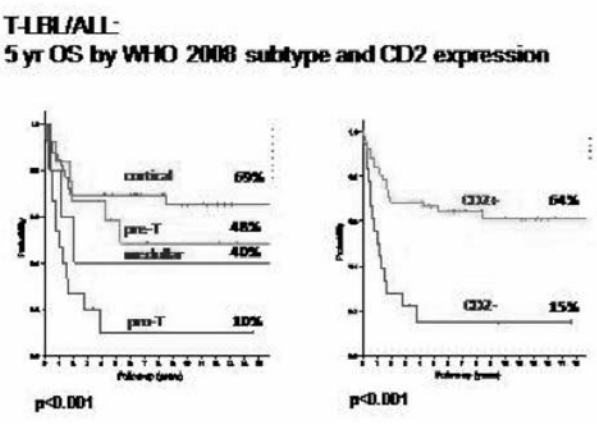

Figure 1.

Summary/Conclusions: Survival of T-LBL/ALL pts depends on CD1a and CD2 expression as well as on WHO subtype. ETP is a non-uniform category by pro-T/pre-T-cell origin. ETP phenotype was non-significant factor for OS/DFS (p=0.186/p=0.159) unless consistent with pro-T subtype (CD2-), only 1/9 pts alive. Pro-T (CD2-) is an ultra-high risk subtype of T-ALL/LBL and novel treatments are needed to improve pts outcomes.

P163

CLINICAL SIGNIFICANCE OF END OF INDUCTION MINIMAL RESIDUAL DISEASE IN ADULT PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA IN COMPLETE REMISSION AFTER A SINGLE CHEMOTHERAPY COURSE

Background: In pediatric ALL end of induction minimal residual disease (EOI MRD) evaluated at day 29-33 after the first chemotherapy course is a primary determinant of outcome. The significance of EOI MRD in adult ALL is less clear.
Aims: To assess EOI MRD and its impact on survival and relapse risk in adult patients with Philadelphia-negative (Ph-) ALL in complete remission (CR) with a single chemotherapy course.
Methods: Induction chemotherapy for patients in the Northern Italy Leukemia Group 10/07 trial (ClinicalTrials.gov NCT-00795756; *Blood* 2016;128:176 [abstract]) consisted of CY/PDN pre-phase on days -5 to -1, VCR on days 1,8,15,22; Idarubicin on days 2,3; Dexa on days 1-5 and 15-18; L-Asp on days 9,11,13,16,18,20; intrathecal MTX, Ara-C, Dexa on days 1 and 15; and G-CSF from day 4. CR was assessed on day 28 by means of bone marrow morphology and MRD evaluation (RQ-PCR with case-specific probes, sensitivity $\geq 10^{-4}$). EOI MRD was correlated with risk subset, week 10 MRD, systemic relapse incidence (RI) and relapse-free survival (RFS), defining as favorable (*i.e.* negative) a response $<10^{-4}$. In this risk-oriented protocol MRD-based risk stratification was deferred until after early consolidation (week 10), at which point standard- and high-risk (SR, HR) patients with MRD $\geq 10^{-4}$ and very HR patients irrespective of MRD study results were eligible to allogeneic stem cell transplantation.
Results: Of 163 study patients, 139 were in CR after cycle 1 (85.2%), 95 had a sensitive molecular marker (68.3%) and 90 were successfully studied for EOI MRD. Median patient age was 39 years (range 17-67 years), 58.9% were male, 64.4% and 35.6% had B- and T-ALL, respectively, 44.4% were SR, 10% HR and 45.6% very HR (leukocytes >100, highly adverse cytogenetics [18.8%], early/mature-T phenotype). EOI MRD was undetectable in 34 (37.7%) and $<10^{-4}$ in 14 (15.1%), for an overall molecular response of 53.3%, while it was $\geq 10^{-4}$ in 42 ($\geq 10^{-3}$ in 28, 31.1%). EOI MRD did not correlate with patient age and leukocyte count but showed a more favorable course in patients with SR (n=40: $<10^{-4}$ 62.5%, $\geq 10^{-3}$22.5%) rather than HR/very HR features such as pro-B phenotype (n=11: 27.2%, 54.5%), early-T phenotype (n=12: 41.6%, 50%) and highly adverse cytogenetics (n=17: 47%, 41.1%). Notably most EOI MRD responders (42/44, 95.4%) and many of those in the 10^{-4}-10^{-3} range (10/14, 71.4%) were confirmed negative at week 10, contrary to only 7/28 (25%) with EOI MRD $\geq 10^{-3}$(P<0.0001). Five-year RI and RFS rates of EOI MRD negative *vs* positive groups (n=48 *vs* 42) were 15% *vs* 44% (P=0.01) and 68% *vs* 41% (P=0.03), respectively. The correlation between EOI and week 10 MRD identified three distinct prognostic groups: both timepoints negative (n=42), RI 14%, RFS 74%; any one positive (n=19), 43%, 49%; both positive (n=23); 44%, 31% (P=0.04 for RI; P=0.005 for RFS). In a multivariable prognostic model an EOI MRD $\geq 10^{-3}$increased greatly the risk of relapse (hazard ratio 2.67, P=0.01), followed by leukocytosis (>30 in B-ALL and >100 in T-LL; hazard ratio 2.35, P=0.04), while patient age and adverse phenotype or cytogenetics were not significant.
Summary/Conclusions: EOI MRD allows to differentiate early on the patients with the more favorable or most unfavorable treatment outcome, with cutoffs at $<10^{-4}$ (confirmed at week 10) or $\geq 10^{-3}$, respectively. This information can be incorporated into treatment algorithms for adult ALL and prompts the use of new agents/immunotherapeutics in induction regimens to optimize the rate of MRD negative CR.

P164

RESULTS FROM UKALL60+, A UK/HOVON COLLABORATIVE PHASE 2 STUDY IN ELDERLY PATIENTS WITH UNTREATED ACUTE LYMPHOBLASTIC LEUKAEMIA

N. Morley[1,*], A. Kirkwood[2], A. Moorman[3], L. Clifton-Hadley[2], C. Rowntree[4], B. Wrench[5], E. Marwood[2], P. Patrick[2], J. Snowden[6], A. Rijneveld[7], D. Marks[8], A. Fielding[2]
[1]Haematology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, [2]CR UK and UCL Cancer Trials Centre, London, [3]Newcastle University, Newcastle, [4]University Hospital Wales, Cardiff, [5]Barts Health NHS Trust, London, [6]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom, [7]Erasmus Medical Centre, Rotterdam, Netherlands, [8]University Hospitals Bristol NHS Trust, Bristol, United Kingdom

Background: The outcome for older adults with acute lymphoblastic leukaemia (ALL) is unsatisfactory. The UKALL12/ECOG2993 study showed that high risk cytogenetic abnormalities, were common, as well as lower rates of complete remission (CR) and 5 year overall survival (OS) in those aged 55- 65 years of age as compared to younger persons. There are few studies which focus on older patients with ALL, despite an increasing incidence with age.
Aims: A trial to establish age-appropriate baseline chemotherapy from which to design widely-applicable studies of novel agents in older people with ALL.
Methods: UKALL60+ offers five 'Arms' to be decided by investigator and patient choice; Arm A= Philadelphia chromosome positive (Ph+), Arm B= Non-intensive (designed to be delivered primarily out of hospital), Arm C= Intensive, Arm D= Intensive+, and Arm E= Registration only (in which treatment is at investigators discretion, including no active therapy). Any elderly patient with newly diagnosed ALL is eligible. There are no exclusions for co-morbidities, including prior malignancies. Baseline characteristics of each group including Charlson index, ECOG, Karnofsky and CRASH scores are being collected. The primary endpoint is the rate of complete remission (CR) after 2 phases of induction. Secondary objectives include determination of MRD status at 3 time points, EFS and OS at 1 year, treatment related mortality and quality of life.
Results: Since December 2012 85 patients have been recruited (4 excluded due to misdiagnosis) with a median age of 67 years (Range 55 – 83). Median follow up is 18.1 months. ECOG performance status was 0 in 33 (41%), 1 in 37 (46%), 2 in 8 (10%) and ≥3 in 3 (4%). Treatment allocation has been Ph+ n=18, Intensive n=34, non-Intensive n=11, Intensive+ n=7, and Registration only n=11 patients. It is too early to perform a full analysis of the reasons given for choosing each regimen but age appears to be a major factor for Ph-ve patients, with a median age of 74 years (Range 64-82) in the non-Intensive arm compared with 66 years (Range 56 -76) in the Intensive and Intensive+ arms. A total of 36/61 (57%) patients had high risk cytogenetics including *BCR-ABL1* (n=21), low hypodiploidy (n=10), complex karyotype (n=1) and *KMT2A-AFF1* (aka *MLL-AF4*) (n=4). Charlson index and CRASH score data is awaited. At the end of 2 phases of treatment on Arm A (Ph+ve) 17/18 (94%) patients achieved CR. On Arms B-D 27/52 (52%) patients achieved CR. Grade 3/4 AEs were seen in the majority of patients. The most common toxicities were haematological and infections. So far 30 relapses have been reported. 25 are isolated medullary relapses, 4 isolated CNS and combined in 1 patient. To date, 41 deaths have been reported; 32 patients died of ALL, 7 of infection, 1 cardiac and 1 multi-organ failure. Fifty one patients have had a PFS event. The median PFS is 13.2 months in Arm A (Philadelphia +ve) and 11.3 months Arm B-D. The median OS is 19.5 months in Arm A (Philadelphia +ve) and 15.5 months in Arms B-D (Figure 1).

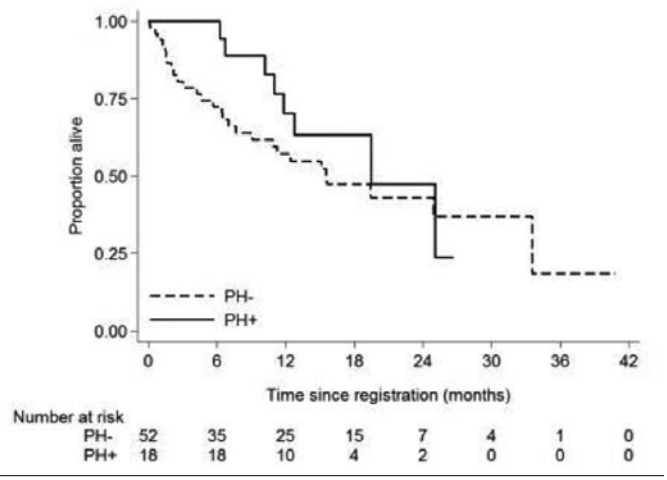

Figure 1.

Summary/Conclusions: ALL in older patients is challenging to treat, with a difficult balance between efficacy and toxicity. We observed a high rate of high risk cytogenetics, especially notable being the rate of low hypodiploidy. Initial high CR rates are seen in those with Ph+ve disease, this does not appear to translate into improved PFS and OS when compared with Philadelphia negative disease. The commonest cause of death in this group is ALL. We will use our baseline data to develop appropriate regimens for future studies of novel agents.

P165

CLINICAL OUTCOMES OF ELDERLY ACUTE LYMPHOBLASTIC LEUKEMIA/LYMPHOMA – A SINGLE INSTITUTION EXPERIENCE

K. Miller[1,*], A. Al-Kali[1], W. Hogan[1], M. Elliott[1], K. Begna[1], N. Gangat[1], M. Patnaik[1], M. Litzow[1], H. Alkhateeb[1]
[1]Division of Hematology, Mayo Clinic, Rochester, United States

Background: Elderly acute lymphoblastic leukemia/lymphoma (ALL) is a rare disease with a poor prognosis and is underrepresented in clinical trials. This thought to be due to comorbidities, early death during induction, lower rates of complete remission, and higher risk of relapse with poor biological features (Gokbuget, Blood, 2013).
Aims: Describe clinical outcomes and prognostic factors of elderly ALL.
Methods: After IRB approval, we performed a retrospective study of patients (pts) age ≥60 diagnosed with ALL from 2000 to 2016 at Mayo Clinic Rochester. Statistical analysis was performed using JMP 10.0 software.
Results: Out of 210 adult ALL pts, we identified 63 (30%) consecutive pts with elderly ALL. The average age at time of diagnosis was 67 (60-82), & 38 (60%) were males. Median follow up was 16.1 months (0.23-126), during which time 40 (63%) deaths occurred; 25 (63%) related to the disease, & 15 (37%) secondary to infection or other causes. *Baseline characteristics at time of diagnosis:* 54 (86%) pts had B-cell phenotype, 19 (35%) were Ph+. Only 9 (14%) pts had T-cell phenotype. 20 (31%) pts had a Charlson Comorbidity Index ≥2 & 17 (27%) presented with ECOG PS ≥2. Median Hgb was 10.6 g/dl (4.9-18.5), WBC 6.2 x 10^9/l(0.5-160.8), PLT 51 x 10^9/l(4-750), peripheral blast 30% (0-95), marrow blast 87.5% (0-100), & LDH 381.5 U/L (141-8440). Lymphoblastic lymphoma was only evident in 3 (5%) pts. Among pts with available data, 34/58 (59%) had B symptoms, 16/57 (28%) lymphadenopathy, 7/57 (12%) splenomegaly, 6/60 (10%) pleural effusions & 10/45 (22%) of pts had CNS leukemia. *Cytogenetics at time of diagnosis:* Of 48 pts with available data, 20 (41%) had complex cytogenetics (≥5 abnormalities), 18 (38%) had a monosomal karyotype, 8 (17%) were hypodiploid, 4 (8%) were hyperdiploid, & 2 (4%) were a mix of hypo- & hyper-diploid. FISH studies were available for 50 pts: 10 (20%) had *CDKN2A* del, 3 (6%) t(4;11) *MLL-AF4*, 2 (4%) t(1;19) *E2A-PBX1*, 1 (2%) *IKZF1* deletion. *Treatment and Outcomes:* 10 (16%) pts received palliative therapy only, which included TKIs, chemotherapy, or hospice. The other 53 (84%) received induction chemotherapy. Only 12 (23%) had an up-front dose reduction due to comorbidities. 32 (60%) received Hyper-CVAD, concomitantly with rituximab in 11 (34%) pts, & TKIs in 9 (28%) pts. 21 (40%) pts received other regimens, of which 14 (67%) had asparaginase-based chemotherapy. Only 2 (4%) pts who received induction chemotherapy died within the first 60 days; both received Hyper-CVAD. Median number of cycles to achieve CR was 1 (1-8) with CR/CRi rate of 93%, & median time to CR1 was 34 days (19-459). 3 pts who underwent palliative chemotherapy achieved CR (all had Ph+ disease & received TKIs). 7 pts (13%) had primary induction failure. 50% of pts relapsed within a median time of 12.6 (3.6-72.8) months. Only 10 pts underwent allogeneic hematopoietic stem cell transplantation (HSCT), of which 2 (20%) relapsed in less than 180 days. Median survival after HSCT was not reached. *Predictors of survival*: Elderly ALL has worse mOS compared to our adult ALL cohort, 17.2 (IQR; 11.7-32.9) *vs* 52.1 (IQR; 27.6-169.9) mon (p=0.0016). In a univariate analysis model which included multiple variables, only ECOG PS ≥2, WBC>30,000, *CDKN2A* del, & CNS leukemia were statistically significant, however only CNS leukemia (p=.0009) & WBC (p=0.0168) retained statistical significance in multivariate mode, with a trend in *CDKN2A* del (p=0.06) (Figure 1).

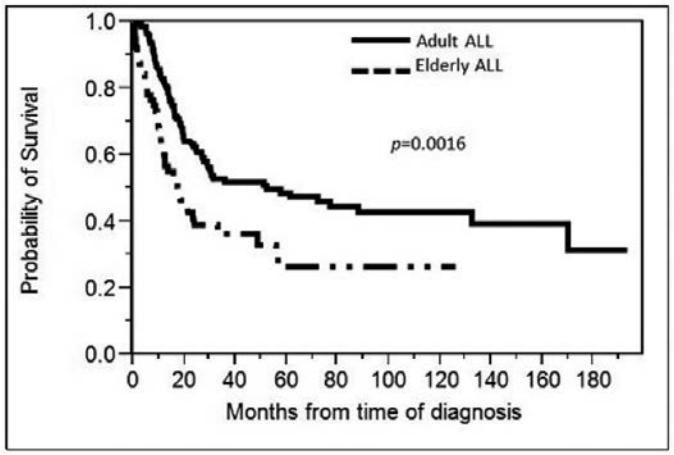

Figure 1.

Summary/Conclusions: Elderly pts with ALL have worse survival compared to younger adults. However, this was not reflected by a low CR rate, or a high rate of mortality during induction, but by grim disease overall. We report for the first time the incidence of 20% for *CDKN2A* del in this disease group. Further studies are needed to confirm this finding, as it could be a target for novel therapies.

P166

MANAGEMENT AND OUTCOME OF ADULT PH+ ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED AT THE "SAPIENZA" UNIVERSITY BETWEEN 1996 AND 2016

S. Chiaretti[1,*], V. Gianfelici[1], R. Agrippino[1], L. Elia[1], F. Paoloni[2], S. Capria[1],

C. Minotti[1], A.P. Iori[1], F. Mancini[1], M.S. De Propris[1], A. Guarini[1], A. Vitale[1], R. Foa[1]
[1]Division of Hematology, Department of Cellular Biotechnologies and Hematology, Sapienza University of Rome, [2]GIMEMA Data Center, Rome, Italy

Background: The outcome of adults and elderly (>60 years) patients with Ph+ ALL has improved since the introduction of tyrosine kinase inhibitors (TKI), used alone or in combination with chemotherapy during induction. Before 2005, all these patients were treated with chemotherapy; from 2005, a TKI-based "chemo-free" induction strategy was applied.
Aims: To evaluate the outcome of patients followed from 1996 at a single Center, and to correlate the short- and long-term responses with: a) induction treatment (chemotherapy or TKI); b) age; c) TKI used (imatinib or dasatinib); d) fusion protein; e) allogeneic stem cell transplant (SCT).
Methods: Sixty-eight patients (29M/39F) were treated; median age was 50 years (20-88) and 16 were elderly patients; 43 cases had the p190 protein, 19 the p210 and 6 had both; the latter 2 groups were merged together for further analyses. Fifty-two patients were enrolled in clinical trials. Median follow-up is 105 months (13-224).
Results: As induction, 28 patients received chemotherapy, 2 chemotherapy+TKI (considered as "chemotherapy±TKI group") and 38 TKI alone (24 imatinib and 14 dasatinib). All cases received TKI during consolidation/maintenance when it became available. All elderly patients but 1 received a TKI alone (plus steroids). Upon induction, 44 patients received consolidation chemotherapy, including 5 elderly. A SCT - carried out virtually only in adults - was performed in first complete remission (CR) in 13 cases (5 in the chemotherapy±TKI and 8 in the TKI groups). Overall, 91% patients achieved a CR; OS and DFS at 100 months are 42% and 45.5%, respectively. Among the 30 patients in the chemotherapy±TKI group, 25 (83%) achieved a CR, 4 were refractory and 1 died in induction; in the TKI group (n=38), 37 (97%) achieved a CR and 1 was refractory. Differences are statistically significant (p=0.03). Refractoriness was more frequent in p210+ than in p190+ cases (12% *vs* 5%): this finding did not translate into significantly different OS and DFS (30% *vs* 48% and 32% *vs* 51%, respectively). When patients were stratified by age, adults had a significantly better OS and DFS at 100 months than elderly (53% *vs* 19%, p= 0.04, and 57% *vs* 20%, p= 0.03, respectively), even more when considering only cases treated with TKI alone (75% *vs* 20%, p=0.01 and 73% *vs* 21.4%, p=0.017, respectively). The TKI used (imatinib or dasatinib) did not impact in adults, while a significant advantage in OS and DFS was observed for elderly patients receiving dasatinib (Figure 1): this might be due to the greater activity of dasatinib and also highlights the importance of consolidation chemotherapy, performed almost exclusively in adults. Considering adults only, within the chemotherapy±TKI group, 5 patients were transplanted and 19 were not: all transplanted cases are in CR, while in the non-transplanted cases 6 are in CR, 11 have relapsed and 2 have died in CR (p=0.01); within the TKI group, 8 patients underwent a SCT and 15 did not: of the transplanted cases, 6 are in CR and 2 have died due to complications, while 11 of the non-transplanted patients are in first CR, 3 have relapsed and 1 has died in first CR (p=n.s.). Of the 5 patients transplanted in second CR, only 1 is alive.

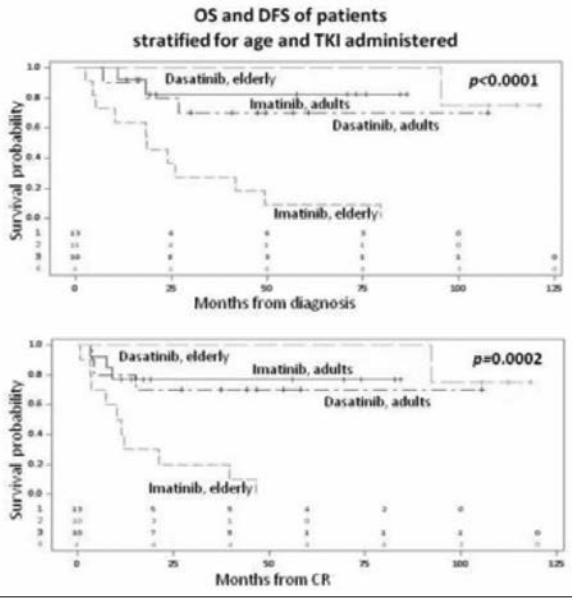

Figure 1.

Summary/Conclusions: This study further underlines the benefit of an induction based on a TKI alone. Since age holds strong prognostic significance, our results suggest that while imatinib followed by consolidation chemotherapy is the optimal choice for adults, in elderly cases dasatinib is more appropriate, since patients are often unfit to receive further chemotherapy. Finally, the advantage of SCT needs to be carefully redefined in the TKI era.

P167

THE TETRASPANIN CD9 IS A PROGNOSTIC MARKER FOR PREDICTING SURVIVAL OUTCOMES OF PEDIATRIC B-PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

K.T. Leung[1,*], K.Y.Y. Chan[1], C. Zhang[1], A.W.K. Leung[1], F.W.T. Cheng[1], J.W.S. Yu[1], T.F. Leung[1], K. Li[1], C.K. Li[1]
[1]Paediatrics, The Chinese University of Hong Kong, Shatin, Hong Kong

Background: B-precursor acute lymphoblastic leukemia (B-ALL) is the most common childhood malignancy, accounting for approximately 30% of pediatric cancers. With advances in risk-adapted chemotherapy, the overall cure rate of newly diagnosed B-ALL is approaching 85% in most developed countries. However, relapse still occurs in ~20% of patients and a significant portion of them are not initially classified in the high-risk disease entity, underscoring the need for development of additional informative prognostic biomarkers.
Aims: CD9, a tetraspanin family protein, regulates multiple physiologic processes including cell migration and adhesion, and has been associated with metastasis and progression of various types of cancers. In this study, we aim to evaluate its expression pattern and prognostic significance in pediatric B-ALL.
Methods: Cell surface CD9 expression on leukemic blasts at disease presentation was characterized by multicolor flow cytometry in a cohort of pediatric B-ALL patients. The CD9 expression status was correlated with clinical parameters, including age, sex, white cell count, cytogenetics and prednisone response. Kaplan-Meier survival analysis was performed to investigate the possible association of CD9 expression with clinical outcomes. The potential role of CD9 expression as a predictor of 5-year survival outcomes was evaluated using Cox regression models.
Results: Among 118 cases tested, blasts of 92 patients (78.0%) were CD9+ (≥20% of CD9-expressing blasts). There were no significant differences in age, sex and white cell count between CD9+ and CD9- patients. Major cytogenetics subgroups were similarly distributed except for hyperdiploidy (all patients were CD9+; P=0.022) and ETV6-RUNX1 translocation (higher prevalence in CD9- patients; P=0.001). Significantly more CD9+ patients were stratified into the intermediate-risk group (P=0.044) and a higher proportion of CD9- patients was stratified into the high-risk group (P=0.025). Besides, CD9- patients had poorer prednisone response (P=0.014). The 5-year overall survival (OS) and relapse-free survival (RFS) rates of CD9+ patients were significantly lower than those in CD9- patients (P ≤0.029). Subgroup analysis revealed remarkably poorer outcomes in CD9+ patients of the high-risk group (P ≤0.045). A similar trend was also observed in patients of the intermediate-risk group but not in the standard-risk group. In univariate analysis, CD9 positivity, age <1 year, white cell count ≥100 × 10^9/L and poor prednisone response were associated with lower RFS rate (P ≤0.050). In multivariate analysis, CD9 positivity (HR=6.0; P=0.019) and poor prednisone response (HR=3.9; P=0.015) remained as independent prognostic factors for lower RFS rates.
Summary/Conclusions: Our data indicate that expression of CD9 was significantly associated with inferior survival outcomes in pediatric B-ALL. The observed difference was most prominent for patients in the high-risk group, suggesting that CD9 expression could potentially be used in conjunction with other known prognostic factors for refinement of risk group stratification. Our study also lays the foundation for future development of CD9-targeted therapy for high-risk and relapsed/refractory pediatric B-ALL.

P168

PEDIATRIC MLL ACUTE LEUKEMIA PATIENTS SHOW DIFFERENTIAL HDAC EXPRESSION

N. Vega-Garcia[1,*], R. Malatesta[1], C. Estella[1], M. Torrebadell[12], S. Gassiot[1], A. Català[2,3], R. Berrueco[2,3], A. Ruiz-Llobet[3], A. Alonso-Saladrigues[3], M. Mesegue[3], M. Trabazo[3], S. Rives[2,3], M. Camos[1,2]
[1]Hematology Laboratory, Institut de Recerca Pediàtrica Hospital Sant Joan de Deu, Barcelona, [2]Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III, Madrid, [3]Clinical Department of Pediatric Hematology and Oncology, Institut de Recerca Pediàtrica Hospital Sant Joan de Deu, Barcelona, Spain

Background: Overexpression of histone deacetylases (HDACs) is a common feature in acute leukemias. Consequently, HDAC inhibitors (HDACi) have emerged as promising targeted therapy. However, non-specific HDACi may lead to accumulation of double stranded DNA lesions, so more selective isoform specific HDACi are needed. Expression patterns of HDACs in childhood leukemia have been scarcely studied.
Aims: To analyze the expression of HDAC isoforms in different subtypes of pediatric leukemia and correlate them with prognosis and clinico-biological features.
Methods: We evaluated the mRNA gene expression profile of class I, II and IV HDAC genes (HDAC 1-11) by quantitative PCR in 126 leukemic pediatric samples and a pool of non-neoplastic samples as calibrator. Patients were treated according to the Spanish Hemato-Oncology Cooperative Group protocols in a single center. The HDAC expression levels in different groups were compared by the Mann-Whitney test. The level of significance was set up at p<0.05. The analyses were performed with SPSS 24.0.

Results: Our series included 69 boys and 57 girls diagnosed with acute leukemia, with a median age of 5.1 years (range 0-17.4 years). We included 12 infant patients (<1 year old). Eighty-two (65%) patients had B-cell precursor acute lymphoblastic leukemia (BCP-ALL), 24 patients T-cell ALL and 20 patients had acute myeloblastic leukemia (AML). Globally, we found higher expression levels of class I HDAC isozymes (HDAC 1, 2, 3 & 8) in leukemic samples as compared to non-neoplastic samples, as previously reported. Interestingly, some HDAC isoforms associated with specific genetic aberrations. Those patients with rearrangement of MLL (KMT2A) gene (n=18, including 9 BCP-ALL and 9 AML; 7 infants and 11 pediatric) showed a significantly higher expression of HDAC9 (p<0.0001) and a statistically significant underexpression of HDAC1 and HDAC3 (p=0.003 & p=0.02, respectively, see Figure 1). Infants (n=12) had also a significantly lower expression of HDAC7 (p=0.043). In the same line, all pediatric patients with pro-B phenotype (CD10 negative) had low levels of HDAC7, but differences did not reach a statistical significance. After a median follow-up of 5.9 years, 15 patients died, with an overall survival (OS) of 96±2% for BCP-ALL, 82±8% for T-ALL and 55±13% for AML patients (p<0.0001). In the BCP-ALL subgroup, the expression of HDACs did not predict outcome, and only CNS infiltration and leukocytosis were unfavorable risk factors for OS. Again, CNS+, high WBC count and presence of minimal residual disease (MRD) post-induction were predictive for worse event free survival (EFS). Although the number of cases is low and these results must be taken with caution, T-ALL patients with the highest expression of HDAC3 (upper quartile) significantly correlated with worse OS (94% *vs* 25%, p=0.001) and a trend towards worse EFS (89% *vs* 53%, p=0.06). The only significant risk factor for EFS in this subgroup was the presence of MRD after induction (p=0.003).

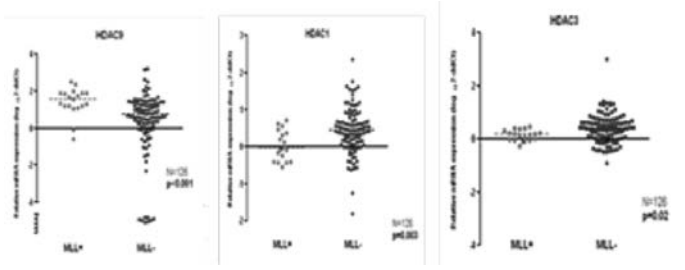

Figure 1.

Summary/Conclusions: We have observed a specific pattern of HDACs expression in pediatric patients with MLL rearrangement. Our study, if further confirmed, suggests that specific HDACi would potentially be a useful targeted treatment for pediatric patients with MLL rearranged leukemia.

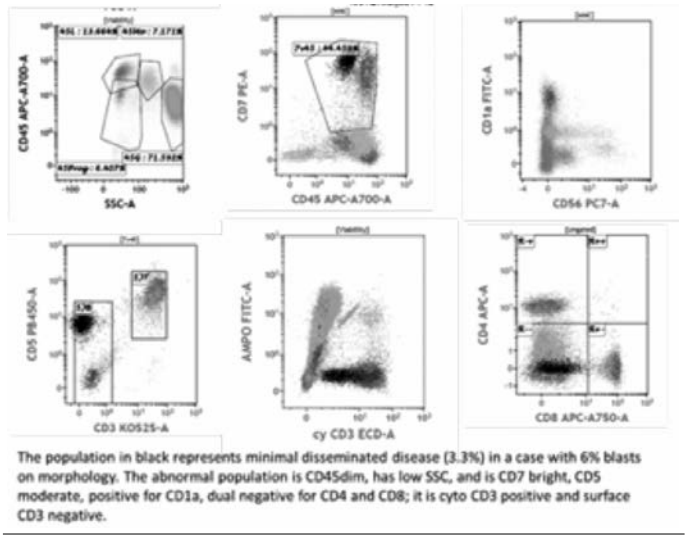
P169

MINIMAL DISSEMINATED DISEASE DETECTION BY FLOWCYTOMETRIC IMMUNOPHENOTYPING IN T-CELL ACUTE LYMPHOBLASTIC LYMPHOMA

G.K. Viswanathan[1,*], P. Tembhare[1], N. Patkar[1], S. Gujral[1], P.G. Subramanian[1]

[1]Hematopathology Laboratory, Advanced Centre for Treatment, Research and Education in Cancer (ACTREC) - Tata Memorial Centre (TMC), Mumbai, India

Background: T-cell acute lymphoblastic lymphoma (T-LBL) with minimal disseminated disease (MDD) is defined as the presence of T-LBL with <25% blasts in the peripheral blood (PB) and/or bone marrow (BM) by morphology and the presence of immunophenotypically abnormal T-lymphoblasts in bone marrow by flowcytometry. Published literature regarding the prevalence and clinical significance of this rare subgroup is sparse. In this study we analysed the presence of minimal disseminated disease is cases of T-LBL with <25% blasts using 8-10 colour flowcytometric immunophenotyping.
Aims: To evaluate the prevalence of minimal disseminated disease in bone marrow in cases of T-cell acute lymphoblastic lymphoma with <25% blasts in PB and BM using 8-10 colour flowcytometric immunophenotyping and evaluate the clinical and immunophenotypic features.
Methods: This study was a retrospective analysis of 42 patients of T-LBL with predominantly lymphomatous presentation with <25% blasts in peripheral and bone marrow. The following parameters were taken into account including complete hemogram, peripheral blood examination, bone marrow morphology and immunophenotyping, CSF analysis, pleural fluid morphology and immunophenotyping, tissue biopsy (lymph node or mediastinal mass), PET-CT findings and LDH levels. Flowcytometric immunophenotyping on bone marrow was performed on a 3 laser 10 color Beckman-Coulter Navios® platform and analysed using Kaluza® software. A minimum of 1,00,000 events were acquired and the presence of minimal disseminated disease was noted.
Results: A retrospective analysis of 42 cases of T-LBL with <25% blasts in peripheral and bone marrow was done. The mean age was 12.2 years (Range:2-48 years). M:F ratio was 1:1.7. Nearly all patients had normal haemoglobin, total leukocyte count and platelet counts. LDH was raised in majority of the patients (Mean 674U/L; N<190U/L). CSF examination was negative in all cases indicating that it is unlikely to have CNS involvement in patients with <25% blasts in PB and BM. Minimal disseminated disease was seen in 12 cases (12/42=28.6%) of cases. Of the 12 cases with minimal disseminated disease two cases were near early T-cell precursor acute lymphoblastic leukemia (near ETP-ALL) type and none were of ETP-ALL type. None of the cases showed circulating blasts in PB. The mean (range) bone marrow blast count in the group without MDD was 2.4% (0-4%) and in the group with MDD was 5.1% (0-15%). In the group with MDD (12 cases), only 5 cases showed >5%blasts/hematogones identifiable by morphology. This indicates flowcytometry is necessary in cases with <5% blasts to pick up cases of MDD. PET-CT was not sensitive to pick-up MDD as increased FDG uptake was seen in only a single case of MDD; it was negative in all cases without MDD. MDD by flowcytometry ranged from 0.007% to 18.5% (mean: 3.6%; median: 4%) (Figure 1).



The population in black represents minimal disseminated disease (3.3%) in a case with 6% blasts on morphology. The abnormal population is CD45dim, has low SSC, and is CD7 bright, CD5 moderate, positive for CD1a, dual negative for CD4 and CD8; it is cyto CD3 positive and surface CD3 negative.

Figure 1.

Summary/Conclusions: Our study shows that minimal disseminated disease is seen in more than one-fourth of cases (28.6%) of T-LBL with <25% blasts in PB and BM. This underlines the importance of flowcytometric evaluation of bone marrow in cases with <25% blasts identified by morphology. The identification of minimal disseminated disease in T-LBL is important as studies have shown inferior event free survival in T-LBL with minimal disseminated disease as compared to patients without minimal disseminated disease.

P170

INOTUZUMAB OZOGAMICIN IN COMBINATION WITH LOW-INTENSITY CHEMOTHERAPY (MINI-HYPER-CVD) AS FRONTLINE THERAPY FOR OLDER PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA: UPDATED RESULTS FROM A PHASE I/II TRIAL

N. Short[1,*], H. Kantarjian[1], S. O'Brien[2], F. Ravandi[1], D. Thomas[1], G. Garcia-Manero[1], N. Daver[1], G. Borthakur[1], N. Jain[1], M. Konopleva[1], K. Sasaki[1], N. Pemmaraju[1], Y. Alvarado[1], J. Jacob[1], R. Garris[1], P. Thompson[1], J. Cortes[1], E. Jabbour[1]

[1]The University of Texas MD Anderson Cancer Center, Houston, [2]The University of California - Irvine, Orange, United States

Background: Older patients (pts) with acute lymphoblastic leukemia (ALL) have poor tolerance of intensive chemotherapy, and novel strategies are needed in this population. In pts with relapsed/refractory ALL, inotuzumab ozogamicin (InO), an anti-CD22 antibody-drug conjugate, has been shown to improve survival compared to salvage chemotherapy.
Aims: We designed a phase I/II trial to evaluate the safety and efficacy of low-intensity chemotherapy (mini-hyper-CVD) plus InO as frontline treatment for older pts with newly diagnosed ALL.
Methods: Pts ≥60 years of age with newly diagnosed Philadelphia chromosome-negative pre-B received mini-hyper-CVD (compared to hyper-CVAD: no anthracycline, 50% dose reductions of cyclophosphamide and dexamethasone, 75% dose reduction of methotrexate, 83% dose reduction of cytarabine). InO was given on day 3 of the first 4 cycles. The first 6 pts received InO at a dose of 1.3 mg/m2 for cycle 1 followed by 0.8 mg/m2 for cycles 2-4; pts 7-34 received 1.8 mg/m2 for cycle 1 followed by 1.3 mg/m2 for cycles 2-4. Due to concern for veno-occlusive disease (VOD), the protocol was amended so that pts 35+ received InO at a dose of 1.3 mg/m2 for cycle 1 followed by 1.0 mg/m2 for cycles 2-4. Rituximab was given during the first 4 cycles in pts with CD20 expression ≥20%; all pts received IT chemotherapy prophylaxis with the first 4 cycles. Pts in CR after 8 cycles then received POMP maintenance for up to 3 years.

Results: Between 4/2012 and 12/2016, 47 pts have been treated, 4 of whom had received 1 cycle of prior therapy and were in CR at the time of enrollment. The median age was 68 years (range, 60-81), and median CD22 expression was 97% (range, 72-100%). Of 43 pts evaluable for response, 42 responded (ORR=98%). Best response was CR in 36 pts (84%), CRp in 5 (12%) and CRi in 1 (2%). MRD negativity by 6-color multiparameter flow cytometry was achieved in 31 of 41 evaluable pts (76%) on day 21 and in 44 of 46 evaluable pts (96%) within 12 weeks of treatment.
The median follow-up was 24 months (range, 1-55 months). 3 pts (6%) underwent allogeneic stem cell transplantation (ASCT) in first remission. Of the 46 responders, 6 pts (13%) have relapsed. 16 pts have died, 1 due to resistant disease, 4 after relapse, 1 after ASCT and 10 in CR/CRp. 21 pts remain on treatment (consolidation, n=3; POMP maintenance, n=19), and 5 pts have completed all therapy. The 3-year continuous CR and OS rates were 72% and 54%, respectively. Compared to a historical cohort of 79 older pts treated at our institution with hyper-CVAD ± rituximab, mini-hyper-CVD+InO resulted in significantly improved OS (3-year OS rate: 54% *vs* 31%; median OS not reached *versus* 16 months; P=0.007).
Treatment was overall well-tolerated. The median times to platelet and ANC recovery in cycle 1 were 22 days (range, 11-91 days) and 16 days (range, 0-49 days), respectively. In cycles 2-8, the median times to platelet and ANC recovery were 22 days and 17 days, respectively. Prolonged thrombocytopenia (*i.e.* lasting >6 weeks) occurred in 37 pts (79%) at some point during therapy; 8 pts (17%) experienced prolonged thrombocytopenia during induction and 36 (77%) during 1 or more subsequent courses. Grade ≥3 transaminase elevation occurred in 9 pts (19%), hyperbilirubinemia in 8 (17%) and hemorrhage in 7 (15%). 4 pts (9%) developed VOD (1 after ASCT, 3 unrelated to ASCT).
Summary/Conclusions: The combination of InO with mini-hyper-CVD is safe and effective in older pts with newly diagnosed ALL, resulting in a promising 3-year OS rate of 54%. These results appear superior to the outcomes of older pts treated with hyper-CVAD.

RECURRENT MYB REARRANGEMENT IN BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM

K. Suzuki[1,*], Y. Okuno[2], Y. Suzuki[3], A. Hama[1], H. Muramatsu[1], M. Nakatochi[2], M. Gunji[4], D. Ichikawa[1], M. Hamada[1], R. Taniguchi[1], S. Kataoka[1], N. Murakami[1], D. Kojima[1], Y. Sekiya[1], E. Nishikawa[1], N. Kawashima[1], A. Narita[1], N. Nishio[2], Y. Nakazawa[5], H. Iwafuchi[6], K. Watanabe[7], M. Ito[4], S. Kojima[1], S. Kato[3], Y. Takahashi[1]
[1]Department of Pediatrics, Nagoya University Graduate School of Medicine, [2]Center for Advanced Medicine and Clinical Research, [3]Department of Pathology and Laboratory Medicine, Nagoya University Hospital, [4]Department of Pathology, Japanese Red Cross Nagoya First Hospital, Nagoya, [5]Department of Pediatrics, Shinshu University School of Medicine, Matsumoto, [6]Department of Pathology, [7]Department of Hematology and Oncology, Shizuoka Children's Hospital, Shizuoka, Japan

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare hematological malignancy that is derived from plasmacytoid dendritic cell precursors. BPDCN tends to occur in elderly people with frequent skin involvement and is associated with an aggressive clinical course and a poor prognosis. Although optimized diagnostics and therapies should improve patient outcomes, the pathobiological and genetic aspects of BPDCN remain unclear.
Aims: We planned this study to identify a critical genetic event in BPDCN, which could provide better understanding of BPDCN pathogenesis.
Methods: We enrolled fourteen patients (five children and nine adults) with BPDCN who were treated in our institutions. We primarily performed RNA sequencing-based comprehensive transcriptome analysis with their samples at the onset to detect gene fusions. These results were then used as the basis for genetic validation studies and functional analyses with an exogenous expression model.
Results: We identified a recurring gene rearrangement that involved the *MYB* proto-oncogene in all five pediatric patients (100%) and four of nine adult patients (44%) with BPDCN. The resulting fusion genes included *MYB-ZFAT* (four patients), *MYB-PLEKHO1* (three patients), *MYB-DCPS* (one patient), and *MYB-MIR3134* (one patient), none of which have been previously reported to our knowledge. The translocations corresponding to these fusions were not detected by the metaphase analysis except in one patient with t(1;6), who harbored *MYB-PLEKHO1*. These fusion genes were detectable at diagnosis and relapse but not at remission. Fluorescence *in situ* hybridization (FISH) analysis efficiently detected the breaking apart of *MYB* in formalin-fixed, paraffin-embedded sections. Consequent to the rearrangement, the negative regulatory domain of *MYB* was truncated, leading to constitutive MYB transcriptional activation, as described in other malignancies. Exogenous *MYB-PLEKHO1* expression in HEK 293T cells led to the upregulation of several known downstream MYB targets. Gene set enrichment analysis also confirmed the activation of MYB target gene sets. The identified significantly upregulated genes included cell surface molecule-encoding genes such as *NCAM1* (also termed *CD56*), *CD68*, *S1PR1*, and *CXCR4*, possibly providing targets for antibody-mediated anticancer therapies. We performed whole-exome sequencing of paired tumor–germline samples at diagnosis for four pediatric patients, which revealed a total of 91 (6–45 per patient) somatic mutations, a relatively large number compared with other pediatric cancers. However, no driver mutations were identified from the existing literature and database entries; only one missense mutation, *KMT2D* p.Cys1403Gly, was present on a driver gene, although this exact mutation had not been previously reported. Furthermore, we performed targeted sequencing covering genes associated with hematological malignancies in the remaining 10 patients. Consequently, children were not found to carry any identifiable driver mutations, whereas all adult patients harbored at least one point mutation in genes such as *TET2*, *ASXL1*, *IKZF1*, *ZRSR2*, *NRAS*, and *EZH2*, most of which were reported to be mutated in BPDCN and myeloid malignancies.
Summary/Conclusions: We identified a high frequency of *MYB* rearrangements that promoted the MYB transcriptional activity in BPDCN. *MYB* split FISH analysis can constitute a valuable diagnostic tool for detecting *MYB* rearrangements. We expect that our findings provide critical insights regarding BPDCN pathogenesis and contribute to molecular biology-oriented diagnostic techniques and molecular-targeted therapies for this intractable malignancy.

BRANCHED CHAIN AMINO ACID METABOLISM REGULATES ALPHA-KETOGLUTARATE HOMEOSTASIS RESEMBLING MUTANT-IDH DRIVEN DNA HYPERMETHYLATION IN AML

S. Raffel[1,2,3,*], M. Falcone[1], N. Kneisel[4], J. Hansson[5], W. Wang[4], C. Lutz[3], L. Bullinger[6], S. Cocciardi[6], P. Wuchter[3], C. Thiede[7], A. Flörcken[8], J. Westermann[8], G. Ehninger[7], C. Herrmann[9], A. D. Ho[3], J. Krijgsveld[5], B. Radlwimmer[4], A. Trumpp[1,2]
[1]Division of Stem Cells and Cancer, German Cancer Research Center, [2]Heidelberg Institute for Stem Cell Technology and Experimental Medicine (HI-

STEM gGmbH), [3]Department of Internal Medicine V, Heidelberg University, [4]Division of Molecular Genetics, German Cancer Research Center, [5]Genome Biology Unit, European Molecular Biology Laboratory (EMBL), Heidelberg, [6]Department of Internal Medicine III, University Hospital Ulm, Ulm, [7]Medical Department 1, University Hospital Carl Gustav Carus, Dresden, [8]Department of Hematology, Oncology and Tumor Immunology, Charité-University Medicine Berlin, Berlin, [9]Division of Theoretical Bioinformatics, German Cancer Research Center, Heidelberg, Germany

Background: The branched chain amino acids (BCAAs) valine, leucine, and isoleucine are essential AAs for the human body. The activity of BCAA metabolism and high levels of the enzyme BCAA Transaminase 1 (BCAT1) have recently been associated with aggressiveness in several cancer entities. However, the mechanistic role of BCAT1 in this process remains uncertain.
Aims: To elucidate the mechanistic link between BCAT1 function and epigenetic deregulation in leukaemia stem cells (LSCs) and consequences on clinical outcome.
Methods: High-resolution proteomics of LSCs, Knockdown and overexpression of BCAT1 in AML patient samples and AML cell lines, Gene set enrichment analysis, BCAA tracing experiments, Xenotransplantations, Metabolomics, DNA methylation arrays, correlative and mechanistic link to clinical data sets.
Results: We performed high-resolution proteomic analysis of human acute myeloid leukaemia (AML) stem cell (LSC) and non-LSC populations, which have been functionally validated by xenotransplantation into NSG mice, and we found the BCAA pathway enriched and BCAT1 overexpressed in LSCs. We show that BCAT1, which transfers α-amino groups from BCAAs to α-ketoglutarate (αKG), is a critical regulator of intracellular αKG homeostasis. Next to its role in the tricarboxylic acid (TCA) cycle αKG is an essential co-factor for αKG-dependent dioxygenases such as EGLN1 and the TET family of DNA demethylases. Knockdown (KD) of BCAT1 in leukaemia cells caused accumulation of αKG resulting in HIF1 protein degradation mediated by EGLN1. This resulted in a growth and survival defect and abrogated leukaemia-initiating potential. In contrast, overexpression (OE) of BCAT1 in leukaemia cells decreased intracellular αKG levels and caused DNA hypermethylation. BCAT1^{high} AML samples displayed a DNA hypermethylation phenotype similar to IDH^{mut} cases, in which TET2 is inhibited by the oncometabolite 2-hydroxyglutarate. High levels of BCAT1 were strongly correlated with shorter overall survival in IDH^{wt}TET2^{wt}, but not IDH^{mut}or TET2^{mut}AMLs. Gene sets characteristic for IDH^{mut} AMLs were enriched both in IDH^{wt}TET^{wt}BCAT1^{high} patient samples and in BCAT1-OE leukaemia cells. BCAT1^{high} samples showed robust enrichment for LSC signatures and paired sample analysis revealed a significant increase of BCAT1 levels upon relapse of the disease.
Summary/Conclusions: In summary, BCAT1 reduces dioxygenase activity by limiting intracellular αKG, thus linking BCAA catabolism to HIF1a stability and DNA hypermethylation. Our results suggest the BCAA-BCAT1-αKG pathway as a therapeutic target to compromise LSC function in IDH^{wt}TET2^{wt} AML patients.

NUCLEAR RE-LOCALIZATION OF NPM1C+ INDUCES DIFFERENTIATION AND CELL GROWTH ARREST

L. Brunetti[1,*], M. Gundry[1], A. Guzman[1], I. Gionfriddo[2], F. Milano[2], F. Mezzasoma[2], M. P. Martelli[2], B. Falini[2], M. Goodell[1]
[1]Baylor College of Medicine, Houston, United States, [2]University of Perugia, Perugia, Italy

Background: *NPM1* mutated (*NPM1*c+) acute myeloid leukemia (AML) is a distinct entity of the 2016 WHO classification of hematopoietic tumors. NPM1 is a multifunctional nucleolar chaperone. All the mutations in NPM1 described so far result in cytoplasmic protein localization (NPM1c) through the acquisition of a nuclear export signal (NES) at the C-terminus, indicating that the cytoplasmic localization is critical for the leukemic phenotype. The most frequent NPM1 mutation is a heterozygous 4bp insertion in exon 12 (mutA).
Aims: Use gene editing and targeted drug treatment to determine whether NPM1 mutated AML cells are dependent on the cytoplasmic localization of NPM1c.
Methods: We sought to introduce indels adjacent to the mutation to disrupt the C-terminal NES in the *NPM1* mutated AML cell line OCI-AML3 and create novel edited alleles encoding for a mutant NPM1 with nuclear localization. Exploiting our optimized CRISPR-Cas9 protocol (Gundry *et al.*, Cell Reports 2016), we electroporated OCI-AML3 cells with an sgRNA spanning the 4bp insertion of mutA (NPM1c sgRNA). As a control, we targeted coding regions of *PTPRC* and *CD19*. Editing efficiency was assessed by high throughput amplicon sequencing. The dynamics of the nuclear re-localization of NPM1c upon drug treatment was studied using a CRISPR-Cas9 engineered NPM1c-GFP OCI-AML3 line generated in house.
Results: While the NPM1mutA allele showed 70-90% indel frequencies, the NPM1wt allele was intact. The novel edited alleles could direct nuclear localization of a reporter GFP-NPM1 fusion construct, and re-localization cytoplasmic NPM1 in edited cells was confirmed by immunofluorescence. Return of NPM1 protein to the nucleus was followed by significant impairment of cell growth (~4 fold decrease in cell counts), colony forming ability (16-20 fold reduction) and engraftment in xenograft models. Flow cytometry analysis showed terminal differentiation and cell cycle arrest in G1 phase (controls 45□3%, NPM1c sgRNA 68□1.5%) 9 days after NPM1c sgRNA transfection. Furthermore, transcriptome analysis on NPM1mutA-targeted and control OCI-AML3 cells revealed a fast and deep downregulation of the HOXA and HOXB cluster genes as well as MEIS1 in treated cells (4 to 5 fold average reduction). In order to verify that nuclear re-localization of NPM1c accounted for the dramatic changes, we treated OCI-AML3 cells with the nuclear export inhibitor selinexor (KPT-330). The impact of KPT-330 treatment mirrored the genome editing experiments, resulting in clear growth arrest, differentiation, and NPM1c localization with similar dynamics. Importantly, selinexor produced an almost complete loss of HOXA, HOXB and MEIS1 expression after 6 days of treatment.
Summary/Conclusions: Allele-specific editing is a powerful tool to probe mechanistic aspects of oncogene dependencies. By achieving nuclear re-localization of mutant NPM1, we demonstrated that cytoplasmic localization of NPM1c is necessary for OCI-AML3 cells to maintain their leukemic phenotype. Drugs promoting mutant NPM1 nuclear localization are attractive candidates for clinical success in *NPM1* mutated AML.

THE LONG NON-CODING RNA HOXB-AS3 REGULATES RIBOSOMAL BIOGENESIS IN NPM1-MUTATED ACUTE MYELOID LEUKEMIA

D. Papaioannou[1,*], A. Petri[2], S. Terreri[3], C. Thrue[2], S. Volinia[4], P. Yan[1], R. Bundshuh[5], G. Singh[6], S. Kauppinen[2], C. Bloomfield[1], D. Adrienne[1], R. Garzon[1]
[1]Comprehensive Cancer Center, The Ohio State University, Columbus, United States, [2]Center for RNA Medicine, Department of Clinical Medicine, Aalborg University, Copenhagen, Denmark, [3]Institute of Genetics and Biophysics (IGB-ABT), National Council of Research (CNR), Naples, [4]Department of Morphology, Surgery and Experimental Medicine, University of Ferrara, Ferrara, Italy, [5]Department of Physics, Department of Chemistry & Biochemistry, Division of Hematology, Department of Internal Medicine, Center for RNA Biology, [6]Department of Molecular Genetics, Center for RNA Biology, The Ohio State University, Columbus, United States

Background: Background: The prognostic significance of long non-coding RNA expression (lncRNAs) in older (≥60 years) patients (pts) with cytogenetically normal acute myeloid leukemia (CN-AML) was recently reported (Garzon *et al.*, 2014). The lncRNA *HOXB-AS3*, which is embedded in the *HOXB*-locus, was identified among the lncRNAs that associated with mutated *NPM1* (*NPM1*mut) in CN-AML.
Aims: Aims: Our aims were to evaluate the biologic significance of *HOXB-AS3* expression in *NPM1*mut AML.
Methods: Methods: *HOXB-AS3* expression profiling was performed by real-time PCR. Knock-down (KD) of *HOXB-AS3* was performed *in vitro* and *in vivo* [in a pt-derived xenograft (PDX) model] with locked nucleic acid-modified gapmers. Comparative proteomic analysis was conducted with a modified version of the RNA antisense purification (RAP) protocol (McHugh *et al.*, 2015). Direct visualization of the *HOXB-AS3* was performed using custom-designed Basecope probes (Advanced Cell Diagnostics, Newark, CA) according to the manufacturer's instructions.
Results: Results: Of 6 AML cell lines that were tested, only OCI-AML3 cells, which harbor *NPM1*mut, showed detectable levels of *HOXB-AS3* expression. Five- and 3-prime Rapid Amplification of cDNA Ends (RACE) assays in OCI-AML3 cells identified 3 previously annotated (NR_033201/NR_033203/ENST000491264) and 1 novel variant of *HOXB-AS3*. *NPM1*mut pt samples exhibited higher expression of *HOXB-AS3* compared to those with wild-type (WT) *NPM1* (*P*=.001*)* and healthy donors (*P*=.001). *In vitro* KD of *HOXB-AS3* led to decreased proliferation of OCI-AML3 cells, as measured by BrdU-based cell cycle analysis (S-phase average% in control *vs* KD: 24% *vs* 16%, *P*=.02). *HOXB-AS3* KD also led to a reduction in the number of formed colonies by OCI-AML3 cells in colony-forming assays (*P*=.002). *HOXB-AS3* KD in *NPM1*mut pt blasts (n=3) led to a decrease in the number of formed colonies (*P*<.001). To evaluate the effect of *HOXB-AS3* KD *in vivo* we generated a murine PDX model by engrafting NSG mice with blasts of a *NPM1*mut AML pt. Treatment of the engrafted mice with nanoparticle-formulated anti-*HOXB-AS3* gapmers led to significant prolongation of survival compared to treatment with non-targeting control gapmers in 2 independent experiments (*P*=.01 and *P*=.005). Mass spectrometry and comparative proteomic analysis of *HOXB-AS3*- and *U1*-specific RNA-protein complexes identified EBP1 and NPM1 as candidate *HOXB-AS3*-binding proteins. RNA-immunoprecipitation experiments validated the interaction of *HOXB-AS3* with EBP1 (20-fold increase of *HOXB-AS3* abundancy in EBP1-precipitate compared to normal IgG control, *P*=.001). Direct visualization of *HOXB-AS3* showed co-localization of the lncRNA and WT NPM1 in the nucleolus. EBP1 has been previously shown to interact with NPM1 and to regulate ribosomal biogenesis and growth of AML cells (Nguyen *et al.*, 2016). We hypothesized that *HOXB-AS3* could affect the EBP1-NPM1 interaction and impact on the ribosomal biogenesis process. In consistency with this hypothesis, *HOXB-AS3* KD led to a decrease in the transcription of rRNA species in OCI-AML3 cells (*P*=.001) and *in vivo*-treated blasts of 2 *NPM1*mut pts (*P*<.001). *HOXB-AS3* KD also led to a reduction of protein synthesis in the AML cells, as measured by incorporation of fluorochrome-tagged tracers in newly translated polypeptides.

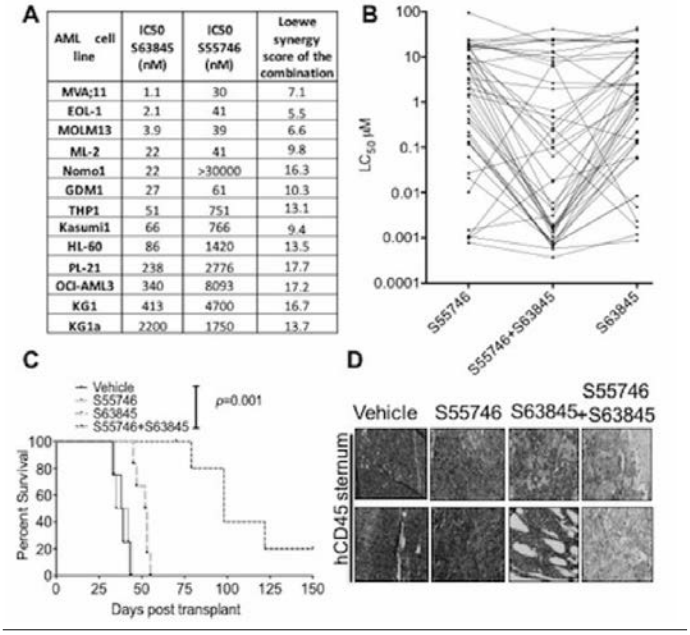
Summary/Conclusions: Conclusions: *HOXB-AS3* is strongly associated with *NPM1* mutations in AML. *HOXB-AS3* interacts with EBP1 and NPM1 and regulates ribosomal biogenesis in the leukemic blasts. From a therapeutic standpoint, *HOXB-AS3* constitutes a promising target, as *in vivo* anti-*HOXB-AS3* treatment prolonged survival in a murine PDX model.

P175

A DUAL BH3-MIMETIC APPROACH TARGETING BOTH BCL-2 AND MCL1 IS HIGHLY EFFICACIOUS AND WELL-TOLERATED IN ACUTE MYELOID LEUKEMIA

D. Moujalled[1,2,*], G. Pomilio[1,2], C. Ghiurau[3], D. Segal[4], T.-C. Teh[1,2], J. Salmon[1,2], S. Rijal[1], P. Lan[4], L. Kraus-Berthier[5], A. Roberts[4], D. Huang[4], A.L. Maragno[3], G. Lessene[4], O. Geneste[3], A. Wei[1,2]
[1]Australian Centre for Blood Diseases, Monash University, [2]Department of Clinical Haematology, The Alfred Hospital, Melbourne, Australia, [3]Oncology R&D Unit, Institut de Recherches Servier , Croissy Sur Seine, France, [4]The Walter and Eliza Hall Institute, Melbourne, Australia, [5]Oncology R&D Unit, Institut de Recherches , Croissy Sur Seine, France

Background: Identification of a chemotherapy-free option for acute myeloid leukemia (AML) represents a highly desired and important research objective. Perturbation of cell survival is an essential hallmark of cancer now amenable to precision targeting by small molecule BH3-mimetics able to inhibit pro-survival BCL-2 (*e.g.* Souers *et al* Nat Med 2013 and Roberts *et al.,* NEJM 2016), BCL-X_L (Lessene *et al.,* Nat Chem Biol, 2013) and MCL1 (Kotschy *et al.*, Nature 2016). We hypothesize that simultaneous pharmacological targeting of BCL-2 and MCL1 will enhance apoptotic death of AML blasts, without increased toxicity to non-malignant cells.
Aims: To assess the feasibility and efficacy of targeting multiple BCL-2 pro-survival proteins using small molecule BH3-mimetics in pre-clinical models of AML
Methods: AML cell lines were obtained from ATCC or DSMZ. S55746 (BCL-2 inhibitor) and S63845 (MCL1 inhibitor with 6-fold higher affinity to human than mouse Mcl1) were obtained from Servier and A1155463 (BCL-X_L inhibitor) from Guillaume Lessene (WEHI). Primary AML cells were obtained from patients providing informed consent. For *in vivo* experiments, NSG; NOD.Cg-*Prkdc*^{scid} *Il2rg*^{tm1Wjl}/SzJ (NSG) or NOD/Rag$^{-/-}$/*Il2rg*^{tm1Wjl} (NRGS) mice were used.
Results: S55746 and S63845 showed strong synergy (Loewe score >5) in 13 AML cell lines tested, suggesting this dual BH3-mimetic targeting approach was highly efficacious (Figure 1A). S55746 and S63845 lowered the LC_{50} in primary AML samples by 10-1000-fold in the majority of cases tested, confirming remarkable anti-leukemic activity across a spectrum of AML cases with diverse cytogenetic and molecular pathologies (Figure 1B).



AML cell line	IC50 S63845 (nM)	IC50 S55746 (nM)	Loewe synergy score of the combination
MVA;11	1.1	30	7.1
EOL-1	2.1	41	5.5
MOLM13	3.9	39	6.6
ML-2	22	41	9.8
Nomo1	22	>30000	16.3
GDM1	27	61	10.3
THP1	51	751	13.1
Kasumi1	66	766	9.4
HL-60	86	1420	13.5
PL-21	238	2776	17.7
OCI-AML3	340	8093	17.2
KG1	413	4700	16.7
KG1a	2200	1750	13.7

Figure 1. (A) Loewe Score (0 → Additive, >1 → Weak Synergy, >2 → Synergy, >5 → Strong Synergy) in AML cell lines (Lehar, Nat. Biotech 2009). (B) LC50 of primary AML after 48hr treatment (C) NSG mice engrafted with MV4;11 AML and treated with i) vehicle, ii) S55746 100 mg/kg/d (x 4 wks), iii) S63845 25mg/kg IV (2x/wk x 4 wks) or iv) combined S55746 and S63845. (D) hCD45+ staining of NRGS sternums showing 2 representative examples of PDX AML one week after treatment with i) vehicle x5d, ii) S55746 100 mg/kg/d x 5d, iii) S63845 25mg/kg IV x 2d and iv) S55746+S63845.

A smaller fraction of AML samples were also sensitised to combined A1155463 and S63845 therapy. Bioluminescent imaging showed rapid and sustained clearance of xenografted MV4;11 AML (*FLT3*-ITD mutant and *MLL* re-arranged) cells, translating into significant prolongation of survival (Figure 1C) from combined S55746+S63845, but not from treatment with either BH3-mimetic alone. Similar *in vivo* efficacy was observed with xenografted OCI-AML3 cells harboring mutant *NPM1* and *DNMT3A*. Patient-derived xenograft models revealed rapid reduction of established AML in the bone marrow one week of treatment with S55746 and S63845 (Figure 1D). Safety and tolerability of this approach was confirmed using normal CD34+ stem and progenitor cells in short-term cell culture (48h) and long-term (2-3 weeks) clonogenic assays and from histological and biochemical examination of mice receiving treated for up to 8 weeks at doses shown to be highly efficacious against AML.
Summary/Conclusions: Dual BH3-mimetic targeting of BCL-2 and MCL1 induces rapid and synergistic cytoreduction of human AML cell line and primary AML samples *in vitro* and *in vivo* and across a diverse range of AML genotypes. We therefore report for the first time, that dual pharmacological inhibition of both BCL-2 and MCL1 represents a novel approach to treating AML without need for additional chemotherapy and with an acceptable therapeutic safety margin. Our results support the translational investigation of dual BH3-mimetic targeting of BCL-2 and MCL1 in the clinic for the treatment of patients with AML.

THE PMLC62A/C65A KNOCK-IN MOUSE MODEL PROVIDES EVIDENCE FOR THE ROLE OF NUCLEAR BODY DISRUPTION IN THE PATHOGENESIS OF ACUTE PROMYELOCYTIC LEUKEMIA

E. Voisset[1,*], E. Moravcsik[1], E. Stratford[2], A. Jaye[1], C. Palgrave[3], R. Hills[4], P. Salomoni[5], S. Kogan[6], E. Solomon[1], D. Grimwade[1]
[1]Medical and Molecular Genetics, King's College London, London, United Kingdom, [2]Tumor Biology, The Norwegian Radium Hospital, Oslo, Norway, [3]School of Veterinary Medicine, University of Surrey, Guildford, [4]Centre for Trials Research, College of Biomedical & Life Sciences, Cardiff, [5]Samantha Dickson Brain Cancer Unit, UCL Cancer Institute, London, United Kingdom, [6]Helen Diller Family Comprehensive Cancer Center, University of California, San Francisco, United States

Background: Acute promyelocytic leukemia (APL) is driven by the oncogene *PML-RARA* which is generated by fusion of the promyelocytic leukemia (*PML*) and retinoic acid receptor alpha (*RARA*) genes, and which strongly interferes with downstream signalling and the architecture of multiprotein structures known as PML nuclear bodies (NBs). NB disruption is a diagnostic hallmark of APL; however, the importance of this phenomenon has only been studied *in vitro*.
Aims: The aim of this study was to decipher the impact of Pml NB disruption in APL pathogenesis.
Methods: We engineered a knock-in mouse model with NB disruption achieved through mutation of key zinc-binding cysteine residues (C62A/C65A) in the Pml RING domain.
Results: While no leukemias or tumors developed in Pml$^{C62A/C65A}$ mice, the forced dimerization of RARα - mediated artificially by linking RARα to the dimerisation domain of the NFκB p50 subunit - in cooperation with NB disruption was associated with doubling in the rate of leukemia (p<0.0001), with a reduced latency period (p=0.008). Moreover, response to targeted therapy with ATRA significantly improved the survival of mice transplanted with Pml^{WT}-p50-RARα or PML-RARα leukemic blasts, but not with Pml$^{C62A/C65A}$-p50-RARα, revealing the essential role of NBs for an effective response to differentiating drug. While formation of the *PML-RARA* fusion is considered an initiating event in APL pathogenesis, it is insufficient for the full leukemic phenotype. Moreover, whole exome sequencing analyses have consistently identified presence of cooperating mutations. Since Pml and Pml NBs have established roles in DNA repair and in the maintenance of genomic stability, we speculated that loss of NB integrity could affect these functions. Here, whole exome sequencing revealed a trend of higher genomic instability in Pml$^{C62A/C65A}$-p50-RARα leukemia as compared to Pml^{WT}-p50-RARα, with detection of mutations found in human APL, including *Kras*, *Ptpn11* and *Usp9y*. Using DNA repair reporter assays, we demonstrated that DNA repair via both non-homologous end joining (NHEJ; p=0.01) and homologous recombination (HR; p=0.006) pathways was less efficient in Pml$^{C62A/C65A}$ primary cells than in Pml^{WT} cells. Importantly, using a PML-RARα-inducible cell line, comparable defects in the NHEJ and HR pathways, which were PML-RARα dependent, were identified. These data were also supported by an increase in sister-chromatid exchange (p<0.0001) and chromosome abnormality (p=0.0002) rates in the context of Pml$^{C62A/C65A}$ *versus* Pml^{WT}. Interestingly, the kinetics of repair of ionising radiation (IR)-induced DNA double-strand breaks, assessed by analysis of γH2AX foci formation and clearance, was not affected. None of the DNA repair players analysed (*e.g.* Blm, Rad51 and 53BP1) failed to form foci in response to IR. However, their basal levels of foci were significantly greater in the presence of Pml$^{C62A/C65A}$ (p<0.04; quantified using Amnis ImageStreamX Mk II imaging flow cytometer). Additionally, we found that Rad51 foci showed a defect in localisation post-IR when Pml$^{C62A/C65A}$ was expressed, with impairment of Rad51 co-localisation and interaction with γH2AX.
Summary/Conclusions: Our study highlights the importance of re-formation of NBs for an efficient response to targeted therapy, the significant contribution

of Pml NB to the effectiveness of DNA damage repair processes, and the manner in which their disruption mediated by the PML-RARα oncoprotein can assist APL pathogenesis.

DECIPHERING THE ONCOGENIC NETWORK OF PRC2 LOSS GUIDED LEUKEMOGENISIS

D. Schneider[1], A. Schwarzer[2,3], S. Knöß[1], J.-H. Klusmann[1], D. Heckl[1,*]
[1]Pediatric Hematology & Oncology, [2]Experimental Hematology, [3]Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Background: Loss of function mutations in EZH2 (including the chromosomal abnormalities -7/-7q) and other PRC2 subunits have been identified in adults with MDS, MPN and AML. Moreover children with JMML and up to 30% of children with Down syndrome related AML present with mutations in PRC2 subunits. Since myeloid neoplasms are elicited by accumulation of cooperating mutations and the study of isolated mutations is unlikely to unveil the molecular processes guiding transformation, we set out to decipher the oncogenic network guided by loss of PRC2-activity.
Aims: Through identification of collaborating mutations driving AML with loss of PRC2 function followed by molecular profiling we aimed to identify novel therapeutic targets in AML.
Methods: To model the complex interplay of mutational networks we performed CRISPR-Cas9 screenings with oncogene/tumor suppressor pools *in vitro* and *in vivo*. Cellular resources generated were subjected to mutational and molecular profiling.
Results: To this end, a 96-well based CRISPR-Cas9 immortalization assay allowing fast and quantifiable genetic cooperation screenings was established. Four out of six CRISPR-Cas9 pools tested –comprised of five genes each and representing 148 mutation combinations- reproducibly transformed LSK cells with distinct clonal output. Transplantation of *in vitro* immortalized clones yielded robust engraftment with multi-lineage contribution in mice but no overt leukemia was detected, indicating that induced mutations select for a preleukemic state *in vitro*. We thus tested every oncogene/tumor suppressor pool from the *in vitro* setting in a murine bone marrow transplantation model with freshly transduced LSK cells which resulted in robust induction of leukemia. Analysing the mutational spectrum of derived clones we were able to raise a list of potential partners cooperating with Ezh2 loss, which highlighted *Nf1(Ras-signaling)*, loss of *Dnmt3a,* and loss of *Runx1* as cooperating partners, whereas loss of cohesin complex subunits (*Smc3, Stag2*) seems to be dispensable during the induction of Ezh2-loss guided leukemogenesis. To define oncogenic dependencies in myeloid malignancies with PRC2-loss we analysed gene expression spectra of the generated samples. While *in vitro* transformed clones presented with distinct expression signatures clearly separating from controls a partially overlapping expression signature could be established. Through identification of these collaborating mutations and the resulting gene expression signature, which will be validated in a CRISPR-Cas9 knock-out screening we aim to identify novel therapeutic targets in AML.
Summary/Conclusions: Our study highlights the power of the CRISPR-Cas9 system to probe oncogenic interaction. Mutational CRISPR screenings *in vivo*, and a newly established *in vitro* CRSIPR-Cas9 immortalization assay for high throughput screening of sgRNA pools, delivered potential cooperating partners of Ezh2 loss in AML, and provides rich cellular resources to identify molecular mechanisms of oncogenic synergies and dependencies.

ACUTE MYELOID LEUKEMIA EVOLUTION CAN BE RECONSTRUCTED BY ANALYSIS OF NON-LEUKEMIC CELLULAR SUBCOMPARTMENTS AND MULTI-LINEAGE ENGRAFTED MICE

B.R.M. Saeed[1,*], L. Manta[1], S. Raffel[1,2], P.T. Pyl[3], W. Wang[1], V. Eckstein[1], A. Trumpp[2], W. Huber[3], A.D. Ho[1], C. Lutz[1]
[1]Internal Medicine V, Heidelberg University Hospital, [2]Division of Stem Cells and Cancer, German Cancer Research Center (DKFZ) and Heidelberg Institute for Stem Cell Technology and Experimental Medicine (HI-STEM gGmbH), [3]Multi-omics and statistical computing, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany

Background: Hematopoietic Stem Cells (HSC) isolated from patients with Acute Myeloid Leukemia (AML) have been shown to carry leukemia-specific mutations leading to the concept of pre-leukemic HSC. In order to understand the evolution from multi-potent pre-leukemic HSC to fully transformed AML, an accurate molecular comparison of patient matched HSC and leukemic cells is essential. Recently we have shown that functionally normal HSC can be separated from a subgroup of AML patients using the surface marker combination $CD34^+CD38^-$ and high ALDH enzyme activity ($CD34^+CD38^-ALDH^+$).
Aims: In this study we aim to understand the leukemic evolution from pre-leukemic HSC to fully transformed AML.
Methods: Whole exome sequencing (WES) of 12 diagnostic AML samples with the matched germ-line controls (T cells or buccal swab) was performed. Leukemia-specific mutations were identified according to specific criteria (*Allele Frequency* (AF) >0.20, *Sorting Intolerant From Tolerant* (SIFT)-Score <0.05, coverage >10 reads, support >2 reads, and GMAF <0.05) and validated. Identified AML-specific mutations were tracked in different cellular compartments (T- and B-cells) as well as in single HSC colonies derived from diagnostic AML samples. To test the functional properties of pre-leukemic HSC *in vivo*, we transplanted bulk AML in NOD/SCID-IL2R^{γnull} (NSG) mice and analyzed human subpopulations (myeloid and lymphoid) of multi-lineage engrafted animals for the presence of leukemia-specific mutations.
Results: WES identified 64 AML-specific mutations. Most cases (8 out of 12) showed 4-6 AML specific mutations per sample (1-18 mutations/ AML) including mutations in genes that are recurrently mutated in AML (DMNT3A, IDH1, IDH2, NRAS and KIT). Tracking of AML-specific mutations in non-leukemic T- and B-cells showed that some AML mutations like DNMT3A, IDH1, IDH2, EZH2 and ZNF536 were already detectable in T- and B-cells indicating their pre-leukemic status. Furthermore, analysis of multi-lineage engrafted xenografts detected leukemia-specific mutations in human myeloid and lymphoid sub-compartments suggesting that these animals were engrafted from functionally normal pre-leukemic HSC. To reconstruct the sequence of pre-leukemic mutations single-cell HSC were seeded and the resulting colonies analyzed for the presence of the respective leukemia specific mutations. Based on the different mutational data, combined with the cellular context in which these were detectable the leukemic evolution of most patients could be reconstructed. In one patient we detected a DNMT3A mutation in myeloid and lymphoid cells, whereas NPM1 and FLT3-ITD mutations were only detectable in leukemic cells proving the pre-leukemic status of DNMT3A in this case. In another patient we found DNMT3A and IDH2 in T- and B-cells whereas Trisomy 8 and a STAG2 deletion were only detectable in leukemic cells. By analyzing colonies from single cell HSC we were able to detect complex pre-leukemic hierarchies with one example in which a ZNF536 mutation could be identified as initiating event that hasn't been described in leukemia yet.
Summary/Conclusions: WES can identify leukemia specific mutations including mutations in genes that haven't been described in AML yet. Tracking of these mutations in various non-leukemic cellular compartments including HSC and multi-lineage engrafted mice allows reconstruction of the individual leukemic evolution. A better understanding of these processes may pave the way for new treatment strategies with the aim to target the relevant leukemic mutations.

P180

THE ESSENTIAL ROLE OF THE ENHANCERS OF POLYCOMB EPC1 AND EPC2 IN MLL-AF9 ACUTE MYELOID LEUKAEMIA IS A 'COMPLEX' STORY

N. Mannion[1,*], X. Huang[2]
[1]Paul O Gorman Leukaemia Research Centre, [2]Paul O'Gorman Leukaemia Research Centre, Institute of Cancer Sciences, MVLS, University of Glasgow, Glasgow, United Kingdom

Background: The Enhancers of Polycomb (EPC) proteins EPC1 and EPC2 are required for the survival of MLL-rearranged acute myeloid leukemia (AML). Most importantly, loss of EPC1 or EPC2 in MLL leukemia stem cells, but not normal hematpoietic stem cells and progenitor cells, leads to the induction of cellular apoptosis. To date little is known about the functional contribution of EPC1 and EPC2 in AML. EPC1 is an essential component of the highly conserved NuA4 histone acetyltransferase complex. Additionally, EPC1 has been found in complexes with the Enhancer of zeste homolog 2 (EZH2), a catalytic core subunit of the histone methyltransferase Polycomb repressive complex 2 (PRC2). NuA4 and PRC2 are two major chromatin modifying complexes encompassing opposing epigenetic activities and both are known to be deregulated in AML.
Aims: A systems biology approach to understand the essential contribution of the homologous chromatin regulatory proteins EPC1 and EPC2 in AML in search for novel therapeutic targets.
Methods: Mass spectrometry (MS) analysis was performed on immunoprecipitated protein using EPC1 antibody from human THP1 *MLL-AF9* AML cell extracts. Chromatin immunoprecipitation (ChIP) was performed using HighCell ChIP Kit and iPure kit V2 (Diagenode) followed by NextSeq500 Illumina sequencing in THP1 cells. ChIP enriched regions were identified using SICER peak calling and ChIPpeakAnno. Lentiviral supernatants were prepared and THP1 cells were infected with viral particles containing pLKO.1 puro lentiviral vectors expressing shRNAs. RNA was extracted 72 hr following lentiviral transductions and whole transcriptome sequencing was performed. DESeq2 was used for differential expression analysis.
Results: MS analysis identified the core NuA4 complex components (TIP60, ING3, RUVBL1, RUVBL2, EP400 and DMAP1) and also revealed additional chromatin modifying proteins (HAT1 and HDAC2) copurify with EPC1. ChIP sequencing analysis on THP1 cells for EPC1 and EPC2 revealed both proteins bind in close proximity to genes enriched for the PRC2-associated repressive histone H3K27 trimethylation signature. Next we examined the genome-wide

histone methylation and acetylation profiles following lentiviral shRNA knockdown (KD) of *EPC1* or *EPC2* in THP1 cells. Interestingly, we find significant changes in histone H3K27 trimethylation levels as well as changes in the levels of histone H3 and H4 acetylation following *KD* of either *EPC1* or *EPC2* expression. Notably, the identified regions demonstrating changes in histone H3K27me3 levels are enriched for PRC2 target genes. RNA sequencing followed by gene-set enrichment analysis indicated significant transcriptional changes in PRC2 regulated genes following lentiviral shRNA knockdown of *EPC1* or *EPC2*. Meta-analysis of this PRC signature identified a sub-group of genes that are directly regulated by the EPC complex which include the monocytic differentiation inducer *MAFB*, the H2A ubiquitin ligase *TRIM37* and the pro-apoptotic tumor suppressor *CMTM3*.

Summary/Conclusions: Our data suggests that EPC1 and EPC2 are required for the recruitment of certain chromatin proteins to form EPC-associated complexes which are essential for the maintenance of an AML epigenetic signature and an aberrant transcriptional profile that supports leukemia stem cell survival. We have identified and characterized the EPC complex components in human AML. Additionally, we have refined a subgroup of PRC target genes that are regulated by the EPC complex which represent potential novel therapeutic targets in human AML. Overall we present a comprehensive analysis of the aberrant epigenomic landscape of THP1 *MLL-AF9* AML cells in relation to EPC1 and EPC2 and provide new insight into their deregulated role in AML.

STROMA-DERIVED FACTORS STIMULATE JAK/STAT SIGNALING IN AML CELLS RESULTING IN RESISTANCE TO BCL2 INHIBITOR VENETOCLAX

R. Karjalainen[1,*], M. Popa[2], M. Liu[1], K.K. Javarappa[1], M. Kontro[3,4], A. Parsons[1], K. Porkka[3,4], K. Wennerberg[1], E. McCormack[2,5], B.T. Gjertsen[2], C.A. Heckman[1]
[1]Institute for Molecular Medicine Finland, FIMM, Helsinki, Finland, [2]Centre for Cancer Biomarkers CCBIO, Department of Clinical Science, University of Bergen, Bergen, Norway, [3]Hematology Research Unit Helsinki, University of Helsinki, [4]Department of Hematology, Helsinki University Hospital Comprehensive Cancer Center, Helsinki, Finland, [5]Department of Internal Medicine, Haukeland University Hospital, Bergen, Norway

Background: The bone marrow (BM) microenvironment is known to protect AML cells from drug therapy. We showed earlier that conditioned medium (CM) from the BM stromal cell line HS-5 increased cell viability and led to resistance to specific drug classes.
Aims: Here, we investigate the mechanisms mediating the BM stromal cell induced resistance to venetoclax and its reversal by ruxolitinib.
Methods: Phospho-flow analysis was done by stimulating AML patient cells with GM-CSF, G-CSF, IL-6, IL-8 or MIP-3α (10 ng/mL) for 20 min, after which the cells were stained with Alexa 647-anti-phospho-Stat5 (pY694), PE188 CF594-anti-phospho-Stat3 (pY705), BV421-anti-phospho-Akt (pS473) and PE-anti-phospho-Erk1/2 (pT202/pY204). For co-culture and transwell assays AML cells were added directly to MSCs from AML patients or separated by a 0.4 µm pore membrane. Vehicle (DMSO), ruxolitinib (300 nM), venetoclax (100 nM) or their combination were incubated for 48h and AML cells labeled with PE-Annexin V, 7AAD, PE-Cy7-CD34, BV605-CD45. *In vivo* drug efficacy was tested on NSG mice inoculated i.v. with MOLM-13^{luc}AML cells. Mice were divided into control, venetoclax (25 mg/kg, i.p.), ruxolitinib (50 mg/kg BID, p.o) and combination groups (all n=6) and treated for 3 weeks, 5 days a week with 2 days off.
Results: To identify the factors contributing to BM mediated drug resistance of AML cells, we analyzed the effect of IL-6, IL-8, MIP-3α, GM-CSF and G-CSF, cytokines enriched in the HS-5 CM, on proliferation of MNCs collected from AML patients. GM-CSF and to some extent G-CSF alone conferred resistance to venetoclax similar to CM that we showed earlier to reduce sensitivity to BCL2 inhibitors. To identify the impact of stroma-derived factors on cellular signaling we stimulated AML patient cells with CM and analyzed the phosphorylation of STAT3, STAT5, ERK and AKT. Compared to control conditions, CM rapidly induced phosphorylation of STAT5 in primary AML cells. When the effect of individual cytokines was tested, we noted that GM-CSF and G-CSF alone could mimic the effect of CM on cellular signaling. Gene expression data showed the receptor for GM-CSF (CSFR2A) is more highly expressed in AML patient cells compared to healthy controls. Taken together, these results show that cytokines such as GM-CSF from BM stromal cells increase JAK/STAT signaling, which may lead to enhanced survival of AML cells. To determine whether the protective effect of stroma on BCL2 inhibition was dependent on cell-to-cell interactions we cultured AML patient cells either in direct contact with MSCs or separated from stroma with a 0.4 µm pore membrane. 48h treatment with 100 nM venetoclax did not result in significant reduction of CD34+ AML cells regardless of whether AML cells were directly cultured with stroma or separated by a membrane, further indicating that stroma-derived soluble factors are sufficient to reduce sensitivity to venetoclax. Since the most abundant cytokines secreted by HS-5 cells, GM-CSF and G-CSF led to increased phosphorylation of STAT5, a downstream effector of JAKs, we tested a combination of venetoclax and JAK1/2 inhibitor ruxolitinib. We found that ruxolitinib potentiated sensitivity to venetoclax when tested with AML patient cells in HS-5 CM and in co-culture and transwell assays. Significantly, the combination was more effective at reducing tumor burden in a xenograft mouse model of AML than either drug alone.
Summary/Conclusions: In conclusion, our data demonstrate that BM secreted soluble factors drive cytoprotection against BCL2 antagonist venetoclax that can be overcome by combined blockade of JAK/STAT and BCL2 pathways with ruxolitinib and ventoclax in *ex vivo* co-culture models and *in vivo* in an AML mouse model.

P182

IDENTIFICATION OF NOVEL GENE FUSIONS IN ACUTE MYELOID LEUKEMIA WITH COMPLEX KARYOTYPE BY TRANSCRIPTOME ANALYSIS USING RNA SEQUENCING

F. G. Rücker[1,*], X. Gong[2], A. Dolnik[1], M. Hoyos[1], S. Grasedieck[1], J. Biscocho[2], T. Blätte[1], J. Swoboda[1], A.S. Pollack[2], A. Turchiano[1], H. Döhner[1], K. Döhner[1], J.R. Pollack[2], L. Bullinger[1]
[1]Department of Internal Medicine III, University Hospital of Ulm, Ulm, Germany, [2]Department of Pathology, Stanford University, Stanford, United States

Background: Acute myeloid leukemia with complex karyotype (CK-AML), defined as having ≥3 acquired cytogenetic aberrations in the absence of WHO-designated recurring translocations or inversions, represents about 15% of

adult AML cases. Despite having poor outcomes, CK-AML is the least understood at the molecular level, except for the finding that about two-thirds of cases carry *TP53* alterations. In particular, because cytogenetic alterations appear to be distinct among different patients, it is unclear whether they are cause of leukemogenesis, or merely reflect a state of genomic instability.
Aims: We have hypothesized that cytogenetic aberrations in CK-AML create gene fusions that, although not recurrent across patients, nonetheless deregulate cancer genes that contribute to leukemogenesis in individual patients.
Methods: We performed a transcriptome analysis using Illumina paired-end (101bpx2) RNA sequencing of 65 CK-AML cases to identify gene fusions using multiple independent algorithms (as paired reads that flank, or single-reads that span fusion junctions). Identified gene fusions were in part independently validated by array-based genomic profiling and/or long range PCR followed by use of long-read Oxford Nanopore sequencing technology.
Results: We identified 54 gene fusion events in 30 of the 65 cases (46%) with up to four fusions per case. All fusions are supported by 10-50+ junction-spanning reads, and most are independently supported and/or validated by evidence of genomic DNA breakpoints from array-based genomic profiling and/or long range PCR, respectively. About 35% of the fusions were in-frame, encoding chimeric proteins. The remainder encoded either C-terminally truncated 5' fusion partners, or else N-terminally truncated (or rarely full-length) 3' fusion partners in instances where the 5' partner contributed only the 5'UTR. In many instances, the fusions are predicted to lead to the overexpression or chimeric activation of known or putative novel cancer genes. Of the 54 fusions, only three (*RUNX1-MECOM*, *MN1-ETV6*, and *ETV6-MN1*) were previously reported in AML. The most frequently affected genes were *RUNX1* (n=5), *KMT2A*, and *MECOM* (n=3 each). Based on the affected genes the fusions can be categorized into six functional fusion clusters. Many of the fusions contained at least one known AML gene (n=16; *e.g. RUNX1*, *MECOM*, *DEK*, *ETV6*, *KMT2A*) together with a novel fusion partner, clearly suggesting pathogenic relevance. Other fusions were predicted to disrupt known tumor suppressors (n=4; *e.g. TP53*, *NF1*), or to activate known oncogenes (n=3; *e.g. MYB*). Others encoded chimeric proteins of unclear pathogenic relevance, but that could nonetheless encode novel epitopes created by the fusion junction (n=26).
Summary/Conclusions: Detailed molecular characterization of CK-AML revealed a high incidence of novel gene fusions in about 50% of cases. The affected genes suggest a more general role in leukemogenesis than reflecting a state of genomic instability. Furthermore, identifying gene fusions in each individual patient might lead to more effective, personalized treatments that target the gene fusion itself, enable immunologic therapies against the fusion junction epitopes, and provide private patient-specific biomarkers to track leukemic burden for the monitoring of disease remission and relapse.

P183

H3K27ME3 LEVEL ON THE HIST1 CLUSTER: A POWERFUL EPIGENETIC BIOMARKER THAT STRATIFIES TWO GROUPS OF NPM1-MUTATED AML DIFFERING IN THEIR OUTCOME AND EXPRESSION PROFILE

S. Garciaz[1,2,3,*], C. Chevalier[2], P. Finetti[1,2], J. Vernerey[2], F. Bertucci[2,3,4], B. Calmels[2,3,5], C. Recher[6], C. Chabannon[2,3,5], N. Vey[1,2,3], E. Duprez[2,3]
[1]Hematology, Paoli-Calmettes Institute, [2]INSERM 1068, Cancer research center, [3]Aix-Marseille University, [4]Oncology, [5]Cell therapy facility, Paoli-Calmettes Institute, Marseille, [6]Hematology, Toulouse Cancer University Institute, Toulouse, France

Background: *NPM1* mutation (*NPM1*mut) is the most frequent genetic alteration found in cytogenetically normal acute myeloid leukemia (CN-AML). Patients harboring *NPM1*mut without *FLT3* internal tandem duplication (*FLT3*-ITD) are considered to have favorable outcome. Yet, some of them relapse and become resistant to chemotherapy. Little is known about biological processes underlying treatment failure. Our group previously described a new epigenetic biomarker corresponding to an abnormal gain of the repressive H3K27me3 histone mark within the HIST1 locus on the 6.p22 referred as H3K27me3 HIST1^{high}. This epigenetic biomarker had an impact on clinical outcome as CN-AML patients with H3K27me3 HIST1^{high} had a higher overall survival (OS) and leukemia-free survival (LFS) than H3K27me3 HIST1^{low} patients (Tiberi *et al.*, 2015).
Aims: We studied the impact of H3K27me3 HIST1 in an *NPM1*mut CN-AML cohort. Firstly, we asked whether H3K27me3 HIST1 could help to stratify *NPM1*mut CN-AML patients independently of known genetic alterations. Secondly, we studied gene expression profile (GEP) related to H3K27me3 HIST1 to explore biological pathways associated with treatment failure.
Methods: Blood or bone marrow samples with at least 70% blast involvement collected from 2005 to 2014 were recovered from the Paoli-Calmettes Cancer Institute Biobank and analyzed as training set. A validation set of samples collected during the conduct of two GOELAMS clinical trials (LAM2006IR and LAM2007SA) was used for validation. We performed H3K27me3 HIST profiling by chromatin immunoprecipitation followed by quantitative polymerase chain reaction (ChIP-QPCR) on five histone genes of the HIST1 cluster. We also sequenced frequently mutated genes in AML (*FLT3*, *CEBPα*, *DNMT3A*, *IDH1*, *IDH2*, *MLL*, *EZH2*, *TET2*, *P53*, *WT1* and *ASXL1*). GEP was done on Affymetrix whole-transcript DNA microarray and we used gene set enrichment analysis (GSEA, Subramanian *et al.*, 2005) along with the Gene Ontology database as statistical methodology.
Results: We pooled the 103 samples of patients with *NPM1*mut CN-AML of the training and validation sets together. Median age was 60 [37-76] and median leucocyte count was 76 G/L [10-352]. ChIP-QPCR Profiling identified 74 H3K27me3 HIST^{high} and 29 H3K27me3 HIST1^{low} patients. *FLT3*-ITD was found in 33 (43%) of H3K27me3 HIST1^{high} and 18 (38%) of H3K27me3 HIST1^{low} patients. We confirmed that H3K27me3 HIST1^{high} was associated with higher 5-year OS and LFS rates: 37% and 44% *versus* 17% and 19% (p=.005 and .01) for the H3K27me3 HIST1^{high} and the H3K27me3 HIST1^{low} patients, independently of other genetic alterations. Combining our biomarker with *FLT3* mutational status, we identified two subgroups of patients with very different outcome: 49% and 56% *versus* 18% and 18% (p=.004 and .01) for the H3K27me3 *FLT3*wt HIST1^{high} and the *FLT3*wt H3K27me3 HIST1^{low} patients, respectively (Figure 1). We performed GEP for 27 *NPM1*mut patients (12 H3K27me3 HIST1^{low} and 15 H3K27me3 HIST1^{high}). GSEA analysis revealed a strong enrichment in immune functions and leucocyte activation in the H3K27me3 HIST1^{high} group, evoking differentiated AML. While H3K27me3 HIST1^{low} samples had GSEA associated with chromatin remodeling factors and DNA replication. Considering only *FLT3*wt patients, the H3K27me3 HIST1^{low} subgroup had a gene expression signature characterized by a high expression level of genes from the HIST1 cluster which expression is known to be upregulated during S-phase of cell cycle.

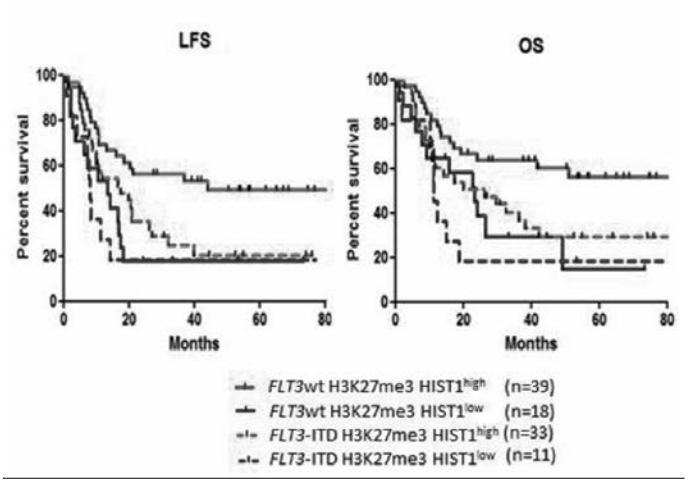

Figure 1.

Summary/Conclusions: the biomarker H3K27me3 HIST1^{high} is correlated with a better LFS and OS in *NPM1*mut CN-AML patient, independently of other known genetic alterations in particular *FLT3* ITD. The worse outcome of *FLT3*-wt H3K27me3 HIST^{low}patients is concomitant with high expression of replication-dependent HIST1 genes that could explain treatment failure.

P184

FUNCTIONAL ASSESSMENT OF NOVEL DIAGNOSTIC FLT3 MUTATIONS AND INHIBITION BY KINASE INHIBITORS

K. Tarlock[1,2,*], T.A. Hylkema[2], J.A. Pollard[3], M.E. Hansen[4], R. Ries[2], R. Sweat[5], S. Meshinchi[2]
[1]Hematology/Oncology, Seattle Children's Hospital, [2]Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, [3]Pediatric Hematology/Oncology, Maine Medical Center, Portland, [4]University of Rochester, Rochester, [5]Arog Pharmaceuticals, Dallas, United States

Background: Somatic mutations in *FLT3* are among the most common events in AML, with *FLT3*/ITD mutations in the juxtamembrane domain (JMD) as well as D835 missense mutations in the kinase domain (KD) the predominant events. Sequencing of *FLT3* in a cohort of 788 children with *de novo* AML treated on contemporary Children's Oncology Group protocols demonstrated that in addition to the previously described *FLT3* mutations (ITD and D835), numerous other variants, including several novel variants, were present in 8% of patients at diagnosis, leading to a cumulative *FLT3* mutation prevalence of 27% in children and young adults. These variants mostly occurred in the JMD and KD and were predicted to activate FLT3, therefore increasing the number of patients who might be amenable to FLT3 inhibitor therapy.
Aims: We evaluated the oncogenic capability of each of these mutations by assessing their ability to result in aberrant FLT3 and STAT5 phosphorylation, as well as response to the tyrosine kinase inhibitors crenolanib and quizartinib.
Methods: Point mutations were introduced into HEK293 cells using retroviral transduction. Following transduction, phosphorylation status of FLT3 (pFLT3) and downstream STAT5 (pSTAT5) were evaluated by immunoblotting. Phosphorylation status was quantified by chemiluminescence analysis and the quan-

tity of protein expression was normalized to actin. That ratio of phosphorylated protein to total protein for FLT3 and STAT5 was determined and normalized to that observed in the D835Y mutation as a positive control. A value of >10% pFLT3 was considered positive. All mutations that resulted in FLT3 phosphorylation were subsequently evaluated for inhibition by crenolanib and quizartinib following 60-minute exposure to the compounds.
Results: A total of 24 non-ITD and non-ALM *FLT3* mutations were evaluated for autonomous FLT3 and STAT5 phosphorylation. Eleven mutations resulted in pFLT3 and pSTAT5, including 4 mutations with >50% pFLT3. All mutations that demonstrated aberrant pFLT3 also had aberrant pSTAT5, however a direct correlation of pFLT3 and pSTAT5 was not always observed. Overall, 87% (n=86 patients) of all non-ITD mutations evaluated resulted in autonomous FLT3 activation. Excluding D835 mutations, 64% (n=39) of patients harbored an activating mutation. Many of the mutations that were not found to be activating had the lowest prevalence, often present in only one patient. Evaluation of inhibition of phosphorylation demonstrated that in every case of aberrant activation, crenolanib resulted in potent inhibition of phosphorylation of FLT3 and STAT5 with an IC50 range of 1.3-13.9 nM and 0.6-6.5 nM respectively. Many of the mutations tested were exquisitely sensitive to crenolanib, with 9 of 10 mutations tested demonstrating an IC50 of pFLT3 inhibition ≤5.6 nM. Inhibition of downstream kinases are necessary for optimal efficacy of any FLT3 inhibitor and phosphorylation of STAT5 was potently inhibited by crenolanib in all cases. Quizartinib inhibited pFT3 and pSTAT5 with an IC50 range of 1.8-151.7 nM and 1-33.9 nM respectively, demonstrating less effective inhibition specifically at mutations including D835Y, D839E, N676K, M664I.
Summary/Conclusions: We have previously presented that *FLT3* mutations, including novel mutations in addition to the FLT3/ITD and D835, are prevalent in children and young adults with AML. Here we demonstrate that many of the non-ITD/835 mutations also result in aberrant FLT3 phosphorylation and are amenable to inhibition by FLT3 inhibitors. Crenolanib resulted in potent inhibition of FLT3 and downstream STAT5 in all mutations tested. This data supports expanding the cohort of pediatric patients with activating FLT3 mutations who may benefit from FLT3 inhibitor therapy beyond those with *FLT3*/ITD.

THE BCL-2 INHIBITOR VENETOCLAX INHIBITS NRF2 ANTIOXIDANT PATHWAY ACTIVATION INDUCED BY HYPOMETHYLATING AGENTS IN ACUTE MYELOID LEUKEMIA

L.X.T. Nguyen[1,*], A. Kalvala[1], E. Troadec[1], B. Kumar[1], S. Forman[1], G. Marcucci[1], V. Pullarkat[2]
[1]City of Hope Medical Center, Duarte, United States, [2]Hematology, City of Hope Medical Center, Duarte, United States

Background: The selective Bcl-2 inhibitor Venetoclax (ABT-199) has shown potent antileukemic activity against Acute Myeloid Leukemia (AML) in preclinical and early clinical studies and impressive results have been achieved using the combination of hypomethylating agents (HMA) with venetoclax suggesting synergy between these agents.
Induction of Reactive Oxygen Species (ROS) is important for the cytotoxicity of various AML therapies including HMA. Induction of ROS by various cytotoxic therapies concurrently activates the Nrf2 antioxidant response pathway which in turn results in induction of antioxidant enzymes that neutralize ROS. Upon ROS induction, the transcription factor Nrf2 is released from its adaptor protein Keap 1 in the cytoplasm whereby Nrf 2 enters the nucleus and binds to antioxidant response element sequences in the promoters of various genes. Nrf 2 pathway activation has been shown to mediate chemoresistance in various cancers including AML. Low ROS levels have been shown to be a hallmark of leukemia stem cells and are critical to their self renewal capacity. In this study, we examined whether Nrf2 inhibition is an additional mechanism responsible for the marked antileukemic activity in AML seen with the combination of HMAs and venetoclax.
Aims: To determine the effect of veneoclax on ROS levels after HMA exposure in AML cells and to examine the effect of Bcl-2 inhibition on Nrf-2 antioxidant pathway activation in response to HMA
Methods: The effect of combination of venetoclax and HMA on ROS levels and apoptosis was measured by flow cytometry. Effcet of venetoclax and HMA on Nrf2 nuclear translocation was analyzed by immunostaining after cellular fractionation. Effcet of venetoclax treatment on the association of Bcl2 with Nrf2 Keap 1 complex was assessed by western blot analysis, immunoprecipitation and *in vitro* assay for ubiquitination.
Results: Our results demonstrated that combination of HMA with venetoclax augmented cellular and mitochondrial ROS induction and apoptosis compared to treatment HMA alone. Treatment of AML cell lines as well as primary AML cells with the hypomethylating agent decitabine resulted in increased nuclear translocation of Nrf2 (Figure 1) and induction of downstream antioxidant enzymes including HO-1 and NQO1. Immunofluoresence studies confirmed the inhibition of nuclear translocation of Nrf2 by venetoclax. Immunoprecipitation studies indicated that Bcl-2, Keap 1 and Nrf2 associate in a protein complex in the cytoplasm and that treatment with venetoclax leads to dissociation of Bcl-2 from the Nrf2/Keap 1 complex and targets Nrf2 to ubiqitination and proteosomal degradation.

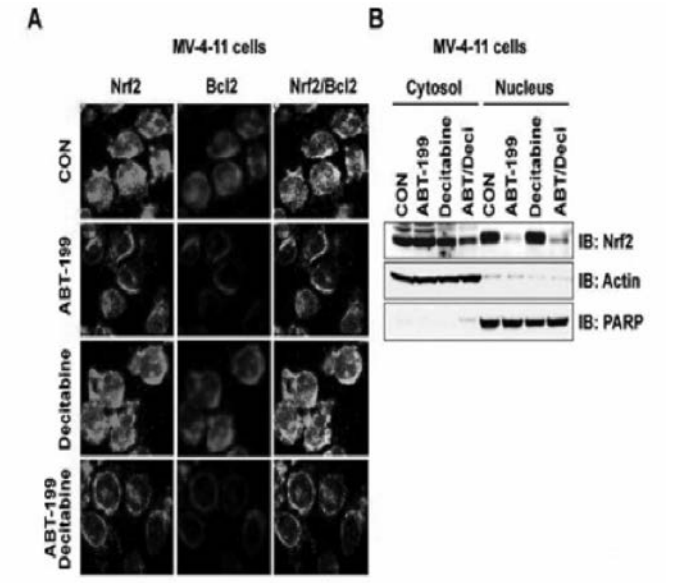

Figure 1.

Summary/Conclusions: In conclusion, inhibition of Nrf2 pathway may explain the marked potentiation of HMA activity by venetoclax that is observed in clinical trials. We show that ROS induction at least partially mediates the cytotoxicity of HMA and ROS induction after HMA treatment is augmented by venetoclax. We demonstrate for the first time that venetoclax is a potent inhibitor of Nrf2 activation via disruption of the association between Nrf2, Keap-1 and Bcl-2.

UNRAVELING EPIGENOMIC REGULATION IN THE EVOLUTION OF RELAPSING PEDIATRIC AML

C. Wiggers[1,2,*], M. Baak[1], M. Creyghton[1], M. Bartels[2]
[1]Hubrecht Institute, [2]Pediatrics, University Medical Center Utrecht, Utrecht, Netherlands

Background: In comparison with pediatric acute lymphoblastic leukemia, pediatric acute myeloid leukemia (AML) is characterized by a high relapse rate (~30%), and lower overall survival rates of 60-70%. It is therefore crucial to increase our insights in pathophysiological mechanisms underlying AML relapse, including chemotherapy resistance, clonal evolution, and clonal selection. There is increasing evidence that epigenetic deregulation is involved in the initiation and progression of cancers, including adult AML. Epigenetic regulation involves the activity of non-coding regulatory DNA elements such as enhancers, which interact with promoters to fine-tune gene expression. Importantly, epigenetic signatures at enhancers are highly cell state specific. Since little is known concerning the epigenetic landscape of pediatric AML, it is crucial to gain more insights into the epigenome of relapsed and non-relapsed AML in children.
Aims: To identify differential epigenomic regulatory pathways involved in AML relapse by exploring the epigenome of relapsed (RP) and non-relapsed pediatric AML patients (NRPs).
Methods: The epigenome of 20 AML patients, harboring known molecular aberrations (including MLL-rearrangement, CBF-related and Flt3-ITD), was analyzed to identify active regulatory pathways. Acetylation of lysine 27 on the tail of histone H3 (H3K27ac) marks active regulatory DNA elements and was therefore used to identify active promoters and enhancers using Chromatin-Immunoprecipitation-sequencing (ChIP-seq) experiments. Additionally, single-cell RNA-seq data were generated for selected AML patients to analyze clonal heterogeneity.
Results: All genomic regions that were significantly enriched by H3K27ac were analyzed, resulting in ~30.000 active promoters and enhancers per sample. Genome-wide Pearson correlation of all enriched regions showed subclustering of patients based on molecular aberration. Interestingly, epigenomic analysis showed that the initial diagnosis (Dx) and the patient's relapse (Rel) sample were highly correlated. Also, single-cell RNA-seq analysis identified two highly identical homogeneous populations at Dx and Rel. Following the fact that no major differences were observed between AML cells at diagnosis and relapse, NRPs were analyzed. Here striking differences in H3K27ac enrichment were observed in MLL-rearranged patients between NRPs and RPs. Enhancers and promoters were differentially enriched at diagnosis, of which Sphk1, a kinase involved in proliferation and survival, was significantly more enriched in RPs, while the promoter of transcription factor ELF1 and nearby located enhancers were active in NRPs only.

Summary/Conclusions: Analysis of promoters and especially enhancers is a highly useful approach to identify cell state specific regulation. Here, we analyzed pediatric AML patients at diagnosis and at relapse to gain more insight into specific cell states which are involved in relapse. Our data revealed high similarity between diagnosis and relapse samples, while, strikingly, in the WHO intermediate-risk group containing MLL-rearranged patients, differential epigenomic regulation was observed between NRPs and RPs. Taken together, our preliminary data suggests that already at diagnosis, AML cells display an epigenomic fingerprint associated with the development of AML relapse during the course of disease. We are currently validating these data.

P188

MECHANISTICALLY INFORMED COMBINATIONS OF SY-1425, A POTENT AND SELECTIVE RARA AGONIST, WITH HYPOMETHYLATING OR ANTI-CD38 TARGETED AGENTS IN AML AND MDS

M. Mckeown[1,*], K. Austgen[2], C. Fiore[2], E. Lee[1], D. Smith[2], C. Fritz[2], T. Lodie[2], E. di Tomaso[1], E. Olson[2]
[1]Translational Medicine, [2]Biology, Syros Pharmaceuticals, Cambridge, United States

Background: The complex pathogenesis of cancer often necessitates combination therapies to optimize patient benefit. Thus, we investigated preclinical combinations of SY-1425 (tamibarotene) and other agents to build on the monotherapy strategy with SY-1425 in biomarker selected AML and MDS patients (Phase 2 study, NCT02807558). Based on the RARα mediated myeloid gene activation of SY-1425, epigenetic priming with hypomethylating agents (HMAs) and CD38 induction were explored.
Aims: We sought to investigate mechanistically informed combinations of SY-1425 with standard of care agents and with potential novel agents in AML. We hypothesized that the HMA azacitidine could prime AML cells for SY-1425 mediated reprogramming by relieving aberrant methylation of RARα target genes and that strong upregulation of the maturation marker CD38 in AML cells by SY-1425 could induce sensitivity to the anti-CD38 therapeutic antibody daratumumab (DARA).
Methods: HMA synergy was tested *in vitro* in AML cell lines over a range of concentrations for SY-1425 and azacitidine. *In vivo* studies used a disseminated patient derived xenograft (PDX) model of AML expressing high levels of RARA. SY-1425 induction of CD38 was assessed by H3K27ac ChIP-seq, RARα ChIP-seq, RNA-seq and flow cytometry. Antibody dependent cell-mediated cytotoxicity (ADCC) was tested in an *ex vivo* co-culture model of human NK cells and AML cell lines.
Results: RARα acts as a repressive transcription factor until bound by SY-1425 leading to potent, targeted activation of myeloid genes. HMAs can further prime this activation by depleting repressive methylation of these target genes. The combination of SY-1425 and azacitidine showed synergy in RARA-high AML cell lines, but not in RARA-low AML cell lines, with combination indices less than 0.5. Co-administration in a RARA-high AML PDX demonstrated superior reduction of tumor burden (<1% detectable tumor cells) *vs* either treatment alone (7% with SY-1425 and 8% with azacitidine). Various combination regimens evaluated in the PDX model over two cycles (56 days) found that 1 week of azacitidine followed by 3 weeks of SY-1425 maximized for anti-tumor activity (<5% AML cells in periphery, bone marrow and spleen) and tolerability (<8% weight loss). RARα binds directly to the *CD38* locus and induces H3K27 acetylation in response to SY-1425 causing CD38 to be one of the most upregulated mRNA transcripts in RARA-high models. SY-1425 treatment of four RARA-high AML cell lines and three RARA-high primary AML patient samples induced cell surface CD38 to high levels comparable to those of DARA sensitive multiple myeloma cells. In contrast, no CD38 induction was observed in RARA-low cell lines. RARA-high AML cell lines treated with SY-1425 and DARA were six fold more sensitive to NK cell mediated ADCC compared to single agent controls and exhibited a 5-10 fold increase in NK cell-dependent activation measured by IFNγ secretion.
Summary/Conclusions: The RARA biomarker dependent synergy with azacitidine and SY-1425 is hypothesized to work through hypomethylation based priming of myeloid differentiation by SY-1425 agonism of formerly repressed RARα target genes. Since CD38 is one of the most strongly induced RARα target genes in response to SY-1425, AML blasts can be sensitized to DARA in a biomarker dependent manner. The preclinical synergistic effects and anticipated non-overlapping clinical toxicity profiles of the respective agents provide a strong rationale for clinical evaluation of each SY-1425 combination in biomarker selected AML and MDS patients.

P189

FLT3 INHIBITION OVERCOMES RESISTANCE TO THE BCL-2 SELECTIVE ANTAGONIST, VENETOCLAX, IN FLT3-ITD MUTANT AML MODELS

D. Sampath[1,*], R. Mali[1], E. Lasater[1], K. Doyle[2], R. Malla[1], E. Boghaert[2], A. Souers[2], J. Leverson[2]
[1]Translational Oncology, Genentech, South San Francisco, [2]Oncology, Abbvie, North Chicago, United States

Background: FLT3 internal tandem duplication (ITD) mutations account for ~20-25% of adult AML cases and are associated with worse prognosis. Although FLT3 inhibitors show clinical activity, relapse occurs quickly. Venetoclax is a potent, selective inhibitor of the anti-apoptotic protein BCL-2 that demonstrated monotherapy activity in relapsed/refractory AML (ORR 19%); however, no activity was seen in FLT3 mutant cases (Konopleva, Can Disc 2016). FLT3-ITD regulates expression of the anti-apoptotic proteins BCL-X_L and MCL-1, but not BCL-2, and FLT3 inhibition synergizes with the dual BCL-2/BCL-X_L inhibitor ABT-737 *in vitro* in FLT3-ITD+ cells (Kohl, Leukemia 2007).
Aims: Expression of BCL-X_L and MCL-1 are known resistance factors to venetoclax, therefore targeting pathways that regulate BCL-X_L or MCL-1 in combination with venetoclax may enhance cell death and improve efficacy. Based on this hypothesis, we interrogated if selective inhibition of BCL-2 by venetoclax in combination with quizartinib, a potent FLT3 inhibitor, resulted in synergistic anti-tumor effects in FLT3-ITD+ AML models.
Methods: FLT3-ITD+ (Molm13 and MV4;11) and wild type (wt; HL60 and OCI-AML3) cell lines were evaluated *in vitro*. Proliferation was measured by cell titer glo and apoptosis by Annexin V staining. *In vivo* efficacy was determined in a MV4;11 xenograft model.
Results: Sensitivity to venetoclax was initially assessed *in vitro*. Dose dependent growth inhibition and induction of apoptosis was observed in the MV4;11, Molm13 and HL60 cell lines following 48hr venetoclax treatment, with the MV4;11 cell line most sensitive. Modulation of BCL-2, BCL-X_L and MCL-1 expression by FLT3 inhibition was determined following 8-24hr treatment with quizartinib. Quizartinib reduced BCL-X_L and MCL-1 protein, but not BCL-2, in the FLT3-ITD+ cells. Quizartinib had no affect on expression of these three proteins in FLT3 wt cells. To interrogate the combination of quizartinib and venetoclax *in vitro*, cell lines were treated for 48hrs with venetoclax, quizartinib or the combination. Combination treatment led to significant reduction in proliferation and increased apoptosis in the FLT3-ITD+ cells compared to either single agent. FLT3 wt cells were not sensitive to quizartinib as a single agent or in combination with venetoclax. The combination translated *in vivo* as synergy between quizartinib and venetoclax was observed in the MV4;11 xenograft model. Together, this data underscores the dependency of these cells on the FLT3-ITD mutation for growth and its use as a predictive biomarker of venetoclax resistance. To determine the dependence of FLT3-ITD+ cells on other anti-apoptotic proteins, cell lines were treated with selective antagonists to BCL-X_L (A1331852) or MCL-1 (A1210477) in combination with venetoclax. Treatment with either antagonist in combination with venetoclax reduced the growth of the cell lines compared to venetoclax alone. However, co-inhibition of BCL-X_L or MCL-1 and FLT3-ITD did not reduce cellular growth compared to quizartinib alone, indicating that maximum anti-tumor responses may be achieved when all three anti-apoptotic proteins are targeted.
Summary/Conclusions: Quizartinib treatment in FLT3-ITD+ AML models decreased expression of the anti-apoptotic proteins BCL-X_L and MCL-1 and synergized with venetoclax *in vitro* and *in vivo* at clinically relevant doses for each compound. These data suggest that co-targeting FLT3-ITD with selective inhibitors and BCL-2 with venetoclax induces apoptosis to a greater extent than FLT3 inhibition alone. Importantly, our preclinical data supports further clinical investigation of this combination to treat FLT3-ITD+ AML.

P190

SPECIFIC TARGETING OF ACUTE MYELOID LEUKEMIA STEM CELLS BY INSULIN-LIKE GROWTH FACTOR BINDING PROTEIN 7

H.J. Verhagen[1], N. van Gils [1], A. van Rhenen[1], A. Rutten[1], M. Smit[1], M.-L. Tsui[1], L.L. de Vos Klootwijk [1], R.X. Menezes[2], M.G. Roemer[1], F. Brocco[1], F. Denkers[1], E. Vermue[1], S. Heukelom[3], S. Zweegman[1], J.J. Janssen[1], G.J. Ossenkoppele[1], G.J. Schuurhuis[1], L. Smit[1,*]
[1]Hematology, [2]Epidemiology and Biostatistics, [3]Radiology, VU University Medical Center, Amsterdam, Netherlands

Background: Only 30-40% of acute myeloid leukemia (AML) patients survive five years after diagnosis. This extreme poor prognosis is mainly caused by treatment failure due to chemotherapy resistance. Leukemic stem cells (LSCs) are thought to be major determinants of AML recurrence due to their potential for self-renewal and chemotherapy resistance. LSCs co-reside with normal $CD34^+CD38^-$ hematopoietic stem cells (HSCs) in the AML bone marrow. Increasing the dose of chemotherapy might eliminate these chemotherapy resistant cells, however will inevitable result in the non-specific elimination of HSCs, delaying or even preventing the recovery of normal hematopoiesis after therapy. To significantly improve the outcome of AML patients, the discovery of alternative therapies that specifically eliminate LSCs while sparing HSC are urgently needed. To develop these specific anti-LSC therapies, identification of genes differentially expressed between LSCs and HSCs and between LSCs and the AML bulk is crucial.
Aims: To identify specific therapeutic strategies that have the potential to eliminate AML relapse-initiating cells.
Methods: We generated gene expression profiles of HSCs, LSCs and leukemic progenitors all derived from the same AML bone marrow and identified Insulin growth factor binding protein 7 (IGFBP7) as one of the top differentially expressed genes. As low IGFBP7 expression is a feature of LSCs, we hypothesized that

decreased expression of IGFBP7 might be associated with decreased chemotherapy sensitivity. To this end, we generated cell lines with IGFBP7 knockdown and subjected the cells to chemotherapy. Furthermore, to test whether increasing the IGFBP7 levels might be a strategy to deplete leukemic (stem) cells, we overexpressed IGFBP7 in or added recombinant human IGFBP7 (rhIGFBP7) to primary AML cells and measured clonogenic capacity, differentiation and cell survival *in vitro*. To study the effect of IGFBP7 on AML cell survival and engraftment potential *in vivo*, primary AML cells were transplanted into immune deficient mice and the mice were subsequently treated with rhIGFBP7. To study the effect of rhIGFBP7 on LSC survival, human AML cells derived from the first transplanted mice were re-transplanted into secondary recipients and engraftment and survival of the mice were monitored.

Results: Knockdown of IGFBP7 results in reduced sensitivity to chemotherapy and comparing matched diagnosis and relapsed AML samples showed that IGFBP7 expression is frequently downregulated at relapse, suggesting a survival advantage of IGFBP7^{low}AML cells during chemotherapy treatment. Importantly, enhancing cytoplasmic or extracellular IGFBP7, by overexpression or addition of rhIGFBP7, resulted in induction of differentiation and apoptosis, increased sensitivity to chemotherapy and inhibited AML blast and leukemic stem/progenitor cell survival *in vitro* and *in vivo*. IGFBP7 had no influence on the survival of normal hematopoietic (stem) cells. Moreover, treatment with rhIGFBP7 can add to chemotherapy treatment by elimination of chemotherapy resistant refractory AML (stem) cells.

Summary/Conclusions: Altogether, these data suggest that addition of IGFBP7 to the currently used chemotherapy regimens might be a promising strategy to specifically eradicate LSCs and decrease AML relapse rates.

Acute myeloid leukemia - Clinical 1

P191

ONGOING PHASE 2 CLINICAL TRIAL OF SL-401 IN PATIENTS WITH BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM: STAGE 1 AND STAGE 2 RESULTS

N. Pemmaraju[1,*], K. Sweet[2], A. Lane[3], A. Stein[4], S. Vasu[5], W. Blum[5], D. Rizzieri[6], E. Wang[7], M. Duvic[1], J. Chen[8], S. Shemesh[8], P. McDonald[8], C. Brooks[8], J. Lancet[2], H. Kantarjian[1], M. Konopleva[1]
[1]MD Anderson Cancer Center, Houston, TX, [2]H. Lee Moffitt Cancer Center, Tampa, FL, [3]Dana-Farber Cancer Institute, Boston, MA, [4]City of Hope National Medical Center, Duarte, CA, [5]The Ohio State University, Colombus, OH, [6]Duke Univiersity Medical Center, Durham, NC, [7]Roswell Park Cancer Institute, Buffalo, NY, [8]Stemline Therapeutics, New York, NY, United States

Background: SL-401 is a targeted therapy directed to interleukin-3 receptor α (CD123), a target overexpressed on a variety of cancers including blastic plasmacytoid dendritic cell neoplasm (BPDCN), a highly aggressive malignancy with poor outcomes and unmet medical need.
Aims: This Phase 2 trial is a single-arm, open-label, study designed to generate efficacy and safety data to support potential registration in BPDCN
Methods: In this ongoing Phase 2 single-arm trial, patients with BPDCN (n=32) or relapsed/refractory (R/R) AML (n=48) received SL-401 as a daily IV infusion at 7, 9, 12, or 16 ug/kg/day for days 1-5 of a 21-day cycle in stage 1. In stages 2 and 3, patients received SL-401 at the dose determined in stage 1.
Results: 32 adult BPDCN patients received SL-401 in stage 1 (n=9) and stage 2 (n=23), including 19 first-line and 13 R/R patients. Stage 3 patients will be reported separately. Median age was 72 years (range: 30-85 years). In stage 1, 12 ug/kg was the highest tested dose for BPDCN; MTD was not reached in BPDCN. Median follow-up was 4.3 months (range: 0.5-22.9 months). ORR of 84% (27/32) was observed in all patients: 95% (18/19) in first-line and 69% (9/13) in R/R. 88% (14/16) of first-line patients treated at 12 ug/kg had a complete remission: CR (n=10), CR with incomplete hematologic recovery (CRi) (n=1) or clinical CR (CRc; residual skin disease) (n=3) based on investigator assessment. 56% (9/16) of these patients were progression free for 4 to 22.9 months (ongoing), including 3 patients on SL-401 in remission (4 to 18 months, ongoing) and 7 patients who were bridged to stem cell transplant (SCT; 3 auto-SCT and 4 allo-SCT). A R/R patient was also bridged to allo-SCT. Overall, most common ≥Grade 3 treatment-related AEs were transaminase elevation (22%) and thrombocytopenia (16%). Safety precautions, including daily monitoring of albumin and body weight during study drug infusions, have been implemented to minimize risk of severe capillary leak syndrome (CLS). Three patients had Grade 5 CLS: BPDCN (7 ug/kg); R/R AML (16 ug/kg); BPDCN (12 ug/kg) out of 118 patients who received SL-401 across all trials and regimens; 3/89 (3.4%) patients of which were enrolled in this clinical trial.
Summary/Conclusions: SL-401 continues to demonstrate single agent activity, including multiple CRs, in patients with BPDCN, with 25% (8/32) of patients bridged to SCT after a major response from SL-401. SL-401 side effect profile consists largely of transaminitis and thrombocytopenia. CLS can be fatal. Side effects have generally tended to decrease in frequency and severity with increasing cycles. Updated data, including detailed safety analysis across all ongoing SL-401 studies will be presented at the meeting.

P192

PROGNOSTIC IMPACT OF SOMATIC MUTATION CLEARANCE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

K. Takahashi[1,*], F. Wang[1], K. Patel[1], C. Bueso-Ramos[1], G. Issa[1], X. Song[1], J. Zhang[1], C. Gumbs[1], F. Ravandi[1], T. Kadia[1], N. Daver[1], C. DiNardo[1], M. Konopleva[1], M. Andreeff[1], J. Cortes[1], G. Garcia-Manero[1], E. Jabbour[1], A. Futreal[1], H. Kantarjian[1]
[1]Leukemia, UT MD Anderson Cancer Center, Houston, United States

Background: Persistence of somatic mutations at the time of complete remission (CR) was associated with poor outcome in patients (pts) with AML.
Aims: To analyze differential pattern of mutation clearance based on the genes and affected pathway and to assess prognostic impact of mutation clearance in AML patients.
Methods: We studied 95 pts with AML who were treated with frontline induction and subsequently achieved CR. We sequenced pre-treatment and CR bone marrow samples by targeted capture sequencing of 295 genes (median 280x coverage). We defined 3 levels of mutation clearance (MC) based on variant allele frequency (VAF): 1) MC2.5, persistent mutation with VAF<2.5%, 2) MC1.0, persistent mutation with VAF<1%, and 3) complete mutation clearance (CMC).
Results: In the pre-treatment samples, we detected 597 mutations in 78 genes in 87 (92%) patients. In the matching CR samples, 62 (10%) and 82 (14%) mutations persisted at VAF≥2.5% and ≥1%, respectively, which corresponded to 43 (49%), 34 (39%), and 30 (34%) patients achieving MC2.5, MC1.0 and CMC, respectively. Table 1 shows the differential patterns of MC based on the mutations and pathways. Mutations associated with clonal hematopoiesis of

indeterminate potential (CHIP), DNA methylation, and splicing pathways had low rate of MC, whereas mutations in transcription factors or receptor tyrosine kinase (RTK) had high rate of MC. Pts who achieved MC1.0 (median 31.2 *vs* 12.5 months, P=0.04) or CMC (median 31.2 *vs* 12.5 months, P=0.049) had significantly better relapse-free survival (RFS).

Table 1.

Gene	MC2.5 (%)	MC1.0 (%)	CMC (%)	Pathway	MC2.5 (%)	MC1.0 (%)	CMC (%)
DNMT3A	21%	17%	14%	**CHIP associated**	33%	24%	22%
NPM1	100%	96%	96%	**DNA methylation**	39%	29%	26%
TET2	35%	35%	35%	**RTK pathway**	88%	87%	83%
FLT3	100%	100%	100%	**Transcription Factors**	94%	83%	77%
CEBPA	100%	89%	89%	**Chromatn-Cohesin**	67%	53%	53%
IDH2	38%	44%	38%	**Splicing**	33%	17%	17%
GATA2	100%	100%	91%				
NRAS	92%	92%	92%				
RUNX1	67%	44%	56%				
WT1	75%	75%	63%				
PTPN11	89%	89%	89%				
TP53	25%	0%	0%				
ASXL1	0%	0%	0%				
NF1	63%	50%	38%				
STAG2	57%	43%	43%				
BCOR	100%	50%	50%				
SRSF2	17%	17%	17%				
IDH1	100%	40%	40%				
SMC3	100%	100%	100%				
KRAS	100%	100%	75%				
SF3B1	100%	33%	33%				

Summary/Conclusions: Somatic mutations associated with CHIP, DNA methylation, and splicing pathways persisted frequently in CR samples suggesting preleukemic origin. Pts with deeper MC had significantly better RFS. Somatic mutation clearance may help risk prediction of AML.

P193

DO EDUCATION AND INCOME AFFECT TREATMENT AND OUTCOME IN ACUTE MYELOID LEUKEMIA IN A TAX-SUPPORTED HEALTH CARE SYSTEM? A DANISH NATIONAL POPULATION-BASED COHORT STUDY

L.S. Østgård[1,2,*], M. Nørgaard[2], B.C. Medeiros[3], L.S. Friis[4], C. Schöllkopf[5], M. Severinsen[6], C.W. Marcher[7], J.M. Nørgaard[1]
[1]Department of Hematology, [2]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, [3]School of Medicine, Stanford University, Stanford, United States, [4]Department of Hematology, Copenhagen University Hospital, Copenhagen, [5]Department of Hematology, Herlev University Hospital, Herlev, [6]Department of Hematology, Aalborg University Hospital, Aalborg, [7]Department of Hematology, Odense University Hospital, Odense, Denmark

Background: No larger study has investigated the association between individual-level education or income level and clinical prognostic markers, treatment, and outcome in acute myeloid leukemia (AML). Understanding how socioeconomic status (SE) affects survival in AML patients may improve prognosis through targeted support among patients with different SE risk profiles.
Aims: We investigate effects of education as a knowledge-related SE factor and income as a measure of material resources in a tax-supported health care system linking individual-level SE information from Statistics Denmark to clinical data from the Danish National Leukemia Registry.
Methods: We conducted a nationwide population-based cohort study and included AML patients ≥25 years diagnosed in Denmark 2000-2014 (end of follow-up, Feb 2016). KM curves and Cox regression (Hazard ratios; HRs) was used to compare survival by education (low, medium, and high) and income level (tertiles). We repeated the survival analysis within educational groups by year of diagnosis (2000-2004, 2005-2009, 2010-2014), stratified by time period, and calculated crude survival (%) at 1, 3, and 5 years. We used logistic regression (odds ratios; ORs) to compare treatment intensity, chance of clinical trial inclusion, and complete remission (CR) between groups. Results were given crude and with different levels of adjustments for age and sex, SES factors, and clinical prognostic markers, overall and stratified by age (<60/≥60 years).
Results: Of 2992 patients, 1588 (53.1%) received remission induction chemotherapy. Forty-five percent (n=1336) completed a low-level education, 38% (n=1138) a medium education, and 17.3% (n=518) a higher education. Patients with higher education tended to be younger and to be male. In intensive therapy patients <60 years, survival was superior in high-education patients evident a year from diagnosis (1-year survival: high 65.2%, HR 1.0, medium 59.2%, adjusted HR 1.55 (CI=1-21-1.98), low 57.7%, 1.47 (CI=1.11-1.93)). Allogeneic transplantation rates in CR1 were significantly higher in high-education compared with low-education patients (16.3% *versus* 8.7%). Only survival in high-education patients improved over time; HR 0.78 (CI=0.61-0.99), medium 0.99 (CI=0.84-1.16), and low 1.03 (CI=0.84-1.27) increasing the survival gap between educational groups (Low: year 2000-2004 HR 1.28 (CI=0.88-1.85), 2004-2009 HR 1.55 (CI=1.01-2.44) 2010-2014 HR 2.09 (CI=1.27-3.44), high 1.0); Figure 1). In older patients, low education was associated with lower chance of intensive chemotherapy (30% *versus* 48%; adjusted OR 0.65 (CI=0.44-0.98)) compared to high-education, however neither CR rates in intensive therapy patients nor survival overall or in intensive therapy patients was affected. Low-income patients where less likely to be enrolled in clinical trials (low-income 22.8%, adjusted OR 0.55 (CI=0.39-0.79) medium 28.2%, adjusted OR 0.71 (CI=0.53-0.94)) compared to high-income (37.2%, HR 1.0), however, income was not associated with therapy intensity, chance of CR, or survival (intensive therapy-only; high income adjusted HR 1.0, medium 0.96 (CI=0.82-1.12), low 1.06 (CI=0.88-1.27)).

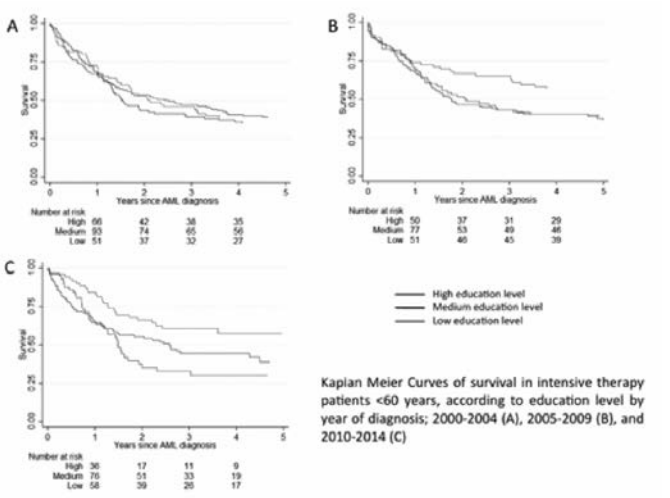

Figure 1.

Summary/Conclusions: In Denmark where health-care is free and uniform, high SE status does not affect treatment intensity in younger patients or response to therapy. However, educational level, but not income, influences alloHSCT rates and has a major impact on survival in younger AML patients. Since 2000, survival improvements have exclusively benefitted well-educated patients and additional attention during treatment and follow-up towards low-educated patients may increase transplantation rates and improve survival.

P194

IDENTIFICATION OF PATTERNS IN CO-OCCURRING MUTATIONS IN AML PATIENTS WITH GERMLINE AND SOMATIC RUNX1 MUTATIONS

U. Borate[1,*], B. Wilmot[1], B. Norris[1], P. Lo[1], D. Bottomly[1], S. McWeeney[1], J. Tyner[1], A. Agarwal[1]
[1]Oregon Health & Science University, Portland, United States

Background: RUNX1 plays a vital role in leukemogenesis through its interaction with core binding factor-β complex and other genes involved in hematopoiesis (1,2). Familial platelet disorder with predisposition to acute myeloid leukemia (FPD/AML) is linked to germline *RUNX1* mutations (3). This autosomal dominant disorder is characterized by thrombocytopenia and potential for transformation to AML. AML patients with somatic *RUNX1* mutations have a poor prognosis (6,7) independent of other risk factors. The role of co-occurring mutations in leukemogenesis in FPD/AML patients with germline *RUNX1* mutations and AML patients with de novo somatic *RUNXl* mutations is not fully understood.
Aims: In order to further characterize co-occurring mutations in patients with both germline and somatic *RUNX1* mutations, we analyzed a large cohort of AML tumor samples along with several paired normal tissue samples.
Methods: We sequenced a cohort of 482 diagnostic bone marrow or peripheral blood samples from AML patients by deep whole-exome sequencing. Samples were collected through the "Beat AML" project, an ongoing program at Oregon Health & Science University in collaboration with the Leukemia & Lymphoma Society. *RUNX1* mutations were classified using VarScan which defined somatic and germline mutations as follows: somatic if p <0.1 and germline if not called as somatic and normal variant allele frequency >0.1.
Results: Twenty AML samples had 21 germline *RUNX1* mutations with a total of 6 different germline variants; 31 other patient samples had 38 somatic *RUNX1* mutations with 31 unique somatic variants. One sample had 2 *RUNX1* germline mutations; 6 samples had >1 somatic RUNX1 mutations. The most common germline variant, missense mutation p.L56S, was found in 16 (76%) of the 21 HCG *RUNX1* mutations identified. Significantly, the germline variants occurred mutually exclusive of the somatic variants. Out of 20 patients with germline *RUNX1* mutations, 16 had co-occurring known pathogenic mutations in AML-related genes. Most significantly, 62% (10/16) and 51% (14/27) of patients with germline or somatic *RUNX1* mutations, respectively, had 7 co-occurring AML-related pathogenic mutations that were exclusive to their cohort (Table 1). Both germline and somatic *RUNX1* mutational cohorts had 12 overlapping co-occurring mutations. The most common mutations, for both groups, were in *FLT3* (14/43), *ASXL1* (8/43), and *IDH2* (7/43) (Table 1). Patient demographics and treatment-related outcomes were similar for both cohorts.

Table 1.

Frequency of germline or somatic *RUNX1* mutation variants and co-occurring mutations identified in 482 AML patients.

Germline versus Somatic *RUNX1* mutation variants				
Mutation Type	Germline Mutation Variants	Number of mutations seen in germline cohort	Somatic Mutation Variant	Number of mutations seen in somatic cohort
Missense	p.L56S	16	p.R162K	2
	Other[a]	3	Other[b]	12
In Frame Deletion	p.S167_R169del	1	None	0
Frame Shift Insertion	p.S322FfsX278	1	p.R250LfsX13	2
			Other[c]	6
Nonsense	None	0	p.E223X	2
			p.R166X	2
			p.R201X	3
			p.R320X	2
			Other[d]	3
Frame Shift Deletion	None	0	Other[e]	4

Co-occurring mutations identified in patients with either somatic (n = 27) or germline (n=16) *RUNX1* mutations						
Seen in germline cohort ONLY	No of mutations seen in germline cohort	Seen in somatic cohort ONLY	No of mutations seen in somatic cohort	Seen in both germline and somatic cohorts	No of mutations seen in germline cohort	No of mutations seen in somatic cohort
NPM1	3	CBL	2	FLT3	7	7

				IDH2	1	6
				U2AF1	1	3
				PHF6	1	1
				NRAS	3	3

a: Three different missense variants were identified in three patients with germline *RUNX1* mutations; b: Twelve different missense variants were identified in twelve patients with somatic *RUNX1* mutations; c: Six different in-frame deletion variants were identified in six patients with somatic *RUNX1* mutations; d: Three different nonsense variants were identified in three patients with somatic *RUNX1* mutations; e: Four different frameshift deletion variants were identified in four patients with somatic *RUNX1* mutations.

Summary/Conclusions: The incidence of *RUNX1* mutations seen in our 482-patient Beat AML cohort (4.3% germline, 6.4% somatic) is consistent with results from other studies (8). Our study suggests that germline and somatic *RUNX1* mutations in AML patients are mutually exclusive, as are several co-occurring pathogenic mutations that contribute to leukemogenesis. Our study adds to the already described mutually exclusive mutations in germline *RUNX1* by identifying *WT1*, *CHEK2*, *CCND3*, and others. Similarly, in samples with somatic *RUNX1* mutations, we found mutually exclusive mutations in *CBL*, *JAK2*, *MLL*, *EZH2* and others, in addition to the previously described *IDH1* (8).Further characterization of these results and analyses of additional samples using our whole-exome sequencing and our bioinformatics platform will help us better elucidate the molecular events underlying AML progression and help us establish novel prognostic/therapeutic markers aimed at early intervention in patients, or their family members, who carry *RUNX1* mutations.

MULTIPLE LEUKEMIC STEM CELL MARKER EXPRESSION IS ASSOCIATED WITH POOR PROGNOSIS IN DE NOVO ACUTE MYELOID LEUKEMIA

T. Yabushita[1,*], Y. Shimomura[1], D. Katoh[1], Y. Ono[1], N. Hiramoto[2], S. Yoshioka[1], N. Yonetani[1], A. Matsushita[1], H. Hashimoto[2], T. Ishikawa[1]
[1]Hematology, Kobe City Medical Center General Hospital, [2]Hematology, Institute of Biomedical Research and Innovation Hospital, Kobe City, Japan

Background: Acute myeloid leukemia (AML) is believed to originate from a small population of leukemic stem cells (LSCs). Current chemotherapy regimens target the majority of more mature leukemic blasts, but cannot efficiently eliminate LSCs, resulting in early treatment failure and relapse. Thus, the expression of LSC-specific markers could be used as a predictive factor of clinical outcomes in AML patients. Recently, the clinical impact of individual LSC markers has been documented in several reports, but the combined effect of different LSC markers remains unexamined.
Aims: This study aimed to estimate the prognostic impact of the expression of multiple LSC markers on the outcome of AML patients.
Methods: Ninety consecutive patients diagnosed with *de novo* AML at our institution and eligible for intensive chemotherapy were enrolled from September 2010 to March 2016. We excluded 10 patients with acute promyelocytic leukemia. This study was approved by the institutional review board of the Ethics Committee and complied with the Declaration of Helsinki. We analyzed the expression of three LSC markers, CD25, CD96, and CD123, in *de novo* AML patients. The expression of these markers on gated leukemic blasts was evaluated using 6-color flow cytometry. When over 20% of leukemic blasts were positive for any marker, the sample was defined as positive for that marker. We stratified *de novo* AML patients into two groups: $LSC^{High}$was defined as positivity for two or three LSC markers, and $LSC^{Low}$was defined as negativity for all markers or positivity for a single LSC marker. The primary endpoint was overall survival (OS). The secondary endpoint was progression-free survival (PFS). OS and PFS were estimated using the Kaplan-Meier method, and assessed using the log-rank test. Multivariate analysis using Cox proportional hazard ratio was performed for OS and PFS.
Results: The median follow-up for patients still alive at the end of the study was 38.9 months (range: 1.5-64.8 months). The median patient age was 60 years (range: 17-78 years). There was no statistical significance between LSC^{High} patients (n=30) and LSC^{Low} patients (n=50) in sex, age, laboratory data, NPM1 mutation, or European Leukemia Net karyotype risk group. FLT3 mutation was associated with the LSC^{High} group (p=0.003). Three-year OS and PFS were significantly better in the LSC^{Low}group than in the LSC^{High}-group (Figure 1) (OS: 65.0% *vs* 18.2%, p <0.001; PFS: 49.3% *vs* 19.4%, p <0.001). In multivariate analysis controlled for age and karyotype (Table1), being in the LSC^{High}group was an independent prognostic factor for OS (hazard ratio: 3.17; 95% CI: 1.64-6.15; p <0.001) and PFS (hazard ratio: 2.25; 95% CI: 1.24-4.08; p=0.007). Being in the LSC^{High}group had incremental value for OS compared with the karyotype risk (Harrell's C index: 0.80 *vs* 0.70; p = 0.028). Moreover, this classification based on LSC marker expression allowed subgroups with unfavorable prognosis to be identified among patients in the intermediate karyotype risk group (3y-OS 54.6% *vs* 14.5%, p=0.013), as well as those in the favorable karyotype risk group (3y-OS 94.1% *vs* 50.0%, p=0.021).

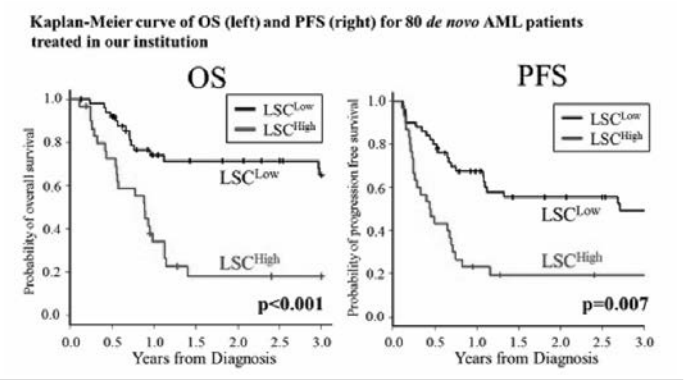

Figure 1.

Table 1. Univariate and multivariate analysis for OS.

	Univariate (OS)		Multivariate (OS)	
Variable	HR (95% CI)	P-value	HR (95% CI)	P-value
Sex	1.04 (0.55-1.97)	0.90		
Age(> 65 years)	1.79 (0.93-3.46)	0.083		
WBC (> 50×10³/μL)	1.67 (0.87-3.18)	0.12		
ELN genetic risk group	3.48 (2.02-6.00)	**<0.001**	3.55 (1.96-6.44)	**< 0.001**
FLT3-ITD^{mut}	2.10 (1.05-4.18)	**0.035**	0.92 (0.42-1.99)	0.83
LSC^{High} group	3.80 (1.96-7.36)	**< 0.001**	3.51 (1.68-7.39)	**<0.001**

Summary/Conclusions: We demonstrated that multiple LSC marker expression predicts poor clinical outcomes in newly diagnosed *de novo* AML patients, and may facilitate better stratification even among patients with intermediate-risk and favorable-risk karyotypes.

P197

NEXT GENERATION SEQUENCING TARGETED PANEL FOR MINIMAL RESIDUAL DISEASE MONITORING IN ACUTE MYELOID LEUKEMIA

V. Mcclain[1,*], A.R. Carson[1], B.A. Patay[1], L. Chamberlain[1], C. Chander[1], S. Zheng[1], W. Huang[1], O. Kiya[1], D. Hubbard[2], D. Caguioa[2], Z. Xie[1], J. Thornes[2], T. Stenzel[1], J. E. Miller[1,2]
[1]Invivoscribe, [2]LabPMM LLC, San Diego, United States

Background: Many personalized therapies for acute myeloid leukemia (AML) have been developed targeting specific biomarkers. Unfortunately, the efficacies of these therapies are inconsistent while the need to determine successful therapies prior to patient relapse is critical. Minimal residual disease (MRD) monitoring can help determine effective treatments and predict potential relapse. While there are now several MRD tests available on the market, most target single or small numbers of biomarkers, which can limit detection of residual AML heterogeneity. Thus, full characterization of a sample may require testing with multiple MRD assays, which can be impractical in a clinical setting. We have developed a target capture-based assay (MyMRD™), which allows characterization of the entire therapeutic AML biomarker repertoire and can inform

the molecular remission status of a patient's malignancy. This targeted panel can identify the mutations in driver clones that cause relapse in ~90% of all AML patients, as well as common drivers in myeloid prolific neoplasms (MPN) and myelodysplasic syndromes (MDS).

Aims: To establish a sensitive and reliable targeted NGS assay to comprehensively detect and monitor the majority of known driver mutations in AML and other myeloid malignancies.

Methods: Whole genome libraries, made from DNA extracted from cell lines and clinical samples, were hybridized with MyMRD probes targeting mutation hotspots in 23 genes associated with AML. In addition to single nucleotide variants (SNVs) and indels in 21 of these genes, 5 structural variant (SV) breakpoints within 3 genes were also targeted. Enriched libraries were sequenced with the MiSeq® platform and analyzed using proprietary Invivoscribe (IVS) MyInformatics™ software. To validate mutations detected by the MyMRD assay, samples were additionally tested with IVS developed capillary electrophoresis (CE) assays and NGS-based assays targeting common mutations in *FLT3* and *NPM1*.

Results: The linearity and limit of detection (LOD) of the MyMRD assay were assessed using data generated from contrived cell line DNA containing known AML driver mutations with a range of variant allele frequencies (VAFs). The assay shows strong linearity (R^2=0.96 – 0.99) in the entire range of tested VAFs (0.1– 20%). Overall, we established a LOD of 0.5% for >95% of the targeted sites in the assay with lower LODs for specific mutations of interest (*e.g.* 0.1% for a 30bp *FLT3* ITD and 0.2% for *FLT3* p.D835Y). In addition, using clinical samples the MyMRD assay shows excellent concordance with the standard *FLT3* CE assays for variants with VAFs above the CE detection threshold (5%). Samples below the CE detection threshold were additionally evaluated with IVS *FLT3* ITD MRD and *NPM1* MRD amplicon assays which showed 100% concordance with the MyMRD panel assay for variants with VAFs above the MyMRD LOD.

Summary/Conclusions: The IVS developed MyMRD targeted panel is a sensitive and reliable assay to monitor residual AML driver mutations. The assay is shown to have excellent linearity and a LOD of 0.5% (tenfold lower than the standard CE assay LOD) at >95% of the targeted sites. Additionally, specific mutations of interest, such as those used for residual disease monitoring (*e.g. FLT3* ITD), demonstrate LODs as low as 0.1%. The MyMRD assay provides an accurate method for detecting mutations in multiple targets in patients and can be used to effectively stratify patients for therapy and clinical trials.

P198

IS IT POSSIBLE TO RELIABLY DETECT CLINICALLY-RELEVANT BIALLELIC CEBPA GENE MUTATIONS USING NGS PANELS?

M. Fernandez-Mercado[1,2,3,*], M.J. Larrayoz[3], I. Vazquez[3], A. Mañu[3], F.J. Gracia-Aznarez[3], F. Prosper[4], M.J. Calasanz[3]

[1]Biomedical Engineering, School of Engineering, University of Navarra, [2]Molecular Oncology, Biodonostia HRI, Donostia University Hospital, San Sebastian, [3]Haemato-Oncology, CIMA LAB Diagnostics, University of Navarra, [4]Haematology and Haemotherapy, Clinic of the University of Navarra, Pamplona, Spain

Background: CEBPA gene encodes a leucine zipper transcription factor that is important for normal myeloid cell differentiation. Biallelic CEBPA (biCEBPA) mutations are associated with favourable prognosis in patients with acute myeloid leukaemia (AML); therefore, accurate molecular testing of this gene is crucial in the clinical setting. Molecular pathology labs routinely analyse CEBPA through fluorescence-based multiplex-PCR fragment analysis or, more frequently, Sanger sequencing. Lately, it is increasingly common to use next-generation sequencing (NGS) technology in the pathology labs, and CEBPA gene is indeed included in the majority of NGS panels commercially available for testing of patients with neoplasias of the myeloid lineage.

Aims: We set ourselves to compare the performance of two different NGS targeted panels and of direct Sanger sequencing for detection of CEBPA molecular aberrations, with a particular focus on biCEBPA mutations.

Methods: DNA specimens from 173 myeloid cases were subjected to Sanger (n=92) or to NGS (n=81) sequencing, including the TruSight Myeloid Sequencing Panel (Illumina) (n=59), and the Ion AmpliSeq AML Community Panel (Thermo Fisher Scientific) (n=22). Cases showing two variants were further analysed through cloning of the whole length of CEBPA and subsequent Sanger sequencing of at least 10 colonies from each case.

Results: We called 10 CEBPA variants affecting 7 samples through NGS. Both NGS panels are designed to cover CEBPA through overlapping amplicons (6 or 9). However, we found that an average of 3.5 amplicons were covered <500x, and more worryingly, we realised that at least one of those amplicons was shallowly (<100x) covered in 97% of the cases. Indeed both panels showed significantly lower average coverage levels of this gene compared to the panel as a whole (Figure 1). This might not be surprising, since CEBPA is encoded within a CpG-rich region, and therefore its amplification needs tailored PCR conditions, hard to address in the multiplexed PCR step included in their library prep protocols. Therefore, both NGS approaches are prone to miss variants. In contrast, Sanger sequencing protocol (which includes optimized PCR conditions for correct amplification of the CEBPA gene) managed to cover the whole length of the gene. We were able to detect 26 variants affecting 20 AML cases through Sanger sequencing. Cases showing two variants were manually curated (through Chromas or IGV tools) to confirm if they affected different alleles. However, in 6 cases both mutations laid on different amplicons, which made not possible to univocally conclude if they were biallelic. These inconclusive cases were subjected to DMSO-Pfu-PCR in order to amplify the whole length of CEBPA coding region, followed by cloning. Colony sequencing showed independent clones harbouring different variants (*i.e. bona fide* biCEBPA mutations) in the majority of the cases, but crucially, not in all of them. This result highlights the need of implementing techniques able to accurately assess CEBPA biallelism, others than plain calling of more than one variant.

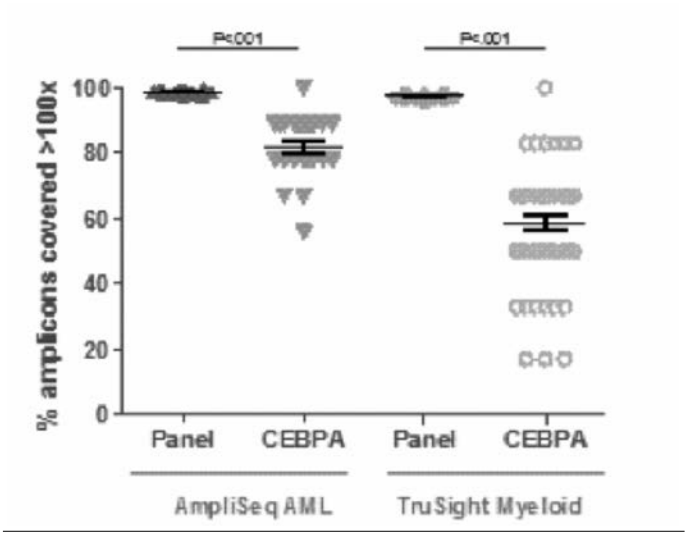

Figure 1.

Summary/Conclusions: Since AML patients with biCEBPA mutations have relatively favourable overall survival, it is important in the clinical setting to accurately assess CEBPA molecular status. In our study, we have tested the ability of three different assays to detect CEBPA mutations in 173 samples. Sanger sequencing was the only method actually covering the entire coding region of CEBPA. Both NGS amplicon-based panels failed to fully cover the coding region of the gene, and therefore have likely missed mutations. Crucially, even when any of the three methods detected more than one variant, cloning studies confirmed biCEBPA mutations only in a fraction of the cases. In summary, none of the amplicon-based tested methods can reliably determine if multiple mutations affect two different alleles; therefore biCEBPA mutations would still need additional confirmation. We are currently exploring the ability of capture-based NGS approaches coupled to appropriately tailored bioinformatic analysis of sequencing data to detect biCEBPA mutations.

P199

EXPERIENCE WITH MINIMAL RESIDUAL DISEASE MONITORING IN AML WITH RUNX1-RUNX1T1: A STUDY ON 186 PATIENTS

A. Hoellein[1,*], M. Meggendorfer[1], A. Fasan[1], W. Kern[1], C. Haferlach[1], T. Haferlach[1]

[1]Munich Leukemia Laboratory, Munich, Germany

Background: The cure rate in AML is dependent on patient's age and performance status, cytogenetics, early blast clearance and sustainable first complete remission. Investigation of minimal residual disease (MRD) is possible by multiparameter-flow cytometry (MFC) or molecular techniques. Recent findings have further depicted a broad spectrum of molecular markers in AML in 99% of pts (TCGA, NEJM, 2013). This broadens the set of targets for MRD and will hopefully help to better individualize treatment strategies. In this analysis we focused on MRD monitoring in *RUNX1-RUNX1T1* positive AML in an unselected cohort.

Aims: To understand the clinical use of PCR based MRD monitoring in AML with *RUNX1-RUNX1T1* fusion.

Methods: Between 2005 und 2017 we investigated a total of 186 intensively treated AML patients with *RUNX1-RUNX1T1* fusion, 130 of them diagnosed at our laboratory and 56 with follow up samples available. 1448 individual samples were analyzed during the course of disease. We applied quantitative real-time PCR to detect *RUNX1-RUNX1T1*/*ABL* ratios. Complete molecular remission (CMR) was defined as one valid qPCR ratio of 0, while low MRD was assigned to patients with a >0 but <0.01 ratio and high MRD was assigned to all patients with a ratio above 0.01. As a comparator log fold change to baseline was independently assessed. Median age was 51 years

(18-83 years). All patients were treated with standard induction and consolidation protocols.

Results: Median time between two investigations was 2.8 months (range for all 0.1-115 months). A complete molecular remission was reached in 90/130 pts (69%) after a median of 5 months. 19/130 (14.6%) pts reached low level MRD and 20/130 (15.4%) high level MRD. Median event free survival (EFS) of patients with CMR was not reached (EFS at 2 years 82%). 16 (18%) of those patients relapsed in the course of follow up with a median time to relapse of 12.7 months (range 4.1 to 38.3 months). Median EFS for MRD low and MRD high patients was 18.4 months and 10.8 months respectively (all 3 groups, p<0.0001). For patients with CMR, rising MRD levels accurately predicted relapse with a median latency of 5.5 months from loss of CMR to relapse. We next used the widely accepted log fold change from baseline to define high and low risk patients in our cohort. 123/130 (95%) patients reached a >3 log fold reduction in *RUNX1-RUNX1T1/ABL* ratio within the first 200 days following first diagnosis. Median EFS for those patients was not reached (EFS at 2 years 66%). The 7/130 (5%) patients with a <3 log fold reduction had a median EFS of 14.7 months (2 groups, p=0.017). A total of 59/185 patients received allogeneic SCT. Among the 130 patients diagnosed at our laboratory 34 (26%) received allogeneic SCT, 12 (9%) were transplanted in first CR and 17 (13%) were transplanted for relapse. Following allogeneic SCT 11/17 patients (65%) reached a second CR with CMR.

Summary/Conclusions: Our data shows that MRD testing is routinely performed in *RUNX1-RUNX1T1* AML outside of clinical studies. Defining MRD levels by *RUNX1-RUNX1T1*/*ABL* ratios resulted in a better classifier for high and low risk patients than log fold change. However, despite CMR 16/90 (18%) patients relapsed with a maximum time from first achievement of CMR of 38.3 months. We conclude that 1) MRD monitoring could serve to guide BMT decisions in *RUNX1-RUNX1T1* positive AML, 2) allogeneic BMT can rescue the majority of relapsed patients and 3) molecular monitoring can reliably identify patients with high risk for relapse.

Acute myeloid leukemia - Clinical 2

P200

NUMBER OF TP53 ABNORMALITIES AND THEIR CLINICAL RELEVANCE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROMES

G. Montalban-Bravo[1,*], C. Benton[1], T. Kadia[1], F. Ravandi[1], J. Cortes[1], N. Daver[1], K. Takahashi[1], C. DiNardo[1], E. Jabbour[1], G. Borthakur[1], N. Pemmaraju[1], M. Konopleva[1], A. Alfonso[1], S. Pierce[1], C. Bueso-Ramos[2], S. Kornblau[1], K. Patel[2], H. Kantarjian[1], M. Andreeff[1], G. Garcia-Manero[1]
[1]Leukemia, [2]Hematophatology, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Mutations in *TP53* can be detected in up to 16-19% patients with acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS). *TP53* mutations confer adverse prognosis irrespective of currently available therapies. The clinical impact of the type and number of *TP53* abnormalities is unclear.
Aims: To evaluate the prognostic impact of the number of *TP53* abnormalities in AML and MDS.
Methods: We evaluated 1401 patients with previously untreated AML or MDS treated at The University of Texas MD Anderson Cancer Center from 2012 to 2016. Sequencing data was obtained by use of a 28 or 53-gene targeted PCR-based next generation sequencing platform. Response was defined following 2003 IWG criteria for patients with AML and 2006 revised IWG criteria for patients with MDS. Generalized linear models were used to study the association of overall response (OR), complete response (CR) and risk factors. Kaplan-Meier produce limit method was used to estimate the median overall survival (OS).
Results: A total of 593 (42%) patients had MDS and 808 (56%) had AML. In a total of 984 (70%) patients, data on therapy with sufficient follow up and response evaluation was available, with 494 (35%) patients receiving therapy with hypomethylating agents (HMAs) and 373 (27%) with chemotherapy regimens. A total of 384 mutations in *TP53*, involving 208 unique mutations, were detected among 300 (21%) patients with *R273H*, *R248W*, *Y220C* and *R175H* being the most prevalent. Overall frequency of *TP53* mutations was higher among patients with MDS (25%, n=146) compared to AML (19%, n=154) (p=0.012) with 251 (84%) of detected mutations happening in patients with complex karyotype (p<0.001). Among patients with *TP53*-mutant disease, 221 (74%) had 1 detectable mutation, 76 (25%) had 2 and 3 (1%) had 3. Additionally, 188 (13%) patients had *TP53* deletions evidenced by presence of monosomy 17 or del(17p). In 167 (89%) of these patients, chr17 abnormalities were detected in the context of a complex karyotype and in 127 (42%) a co-occurring *TP53* mutation was detected. Correlation between *TP53* mutations and deletions (r=0.443, p<0.001) was observed with 172 (12%) patients having 1 *TP53* abnormality, 169 (12%) having 2 and 20 (1%) having 3 abnormalities. Patients with multiple detectable *TP53* mutations were less likely to have co-occurring chr17 abnormalities (79% *vs* 22%, OR 0.28, CI 0.15-0.50, p=0.03). Median follow up was 8.6 months (range 0-167 months). Presence of a *TP53* mutation adversely impacted OS (MDS: 12.4 *vs* 111.7 months, HR=5.98, CI 4.28-8.35, p<0.001; AML: 5.3 *vs* 16.9 months, HR=2.81, CI 2.26-3.50, p<0.001). Increasing number of *TP53* abnormalities negatively impacted OS of patients with AML (Figure 1A) but not that of patients with MDS (Figure 1B). No difference in survival was observed between patients with two *TP53* mutations and those with *TP53* mutation+deletion (p=0.730). Presence and number of *TP53* mutations did not predict for response (OR: 60 *vs* 63%, p=0.498; CR: 34 *vs* 36%, p=0.695) to HMAs, but was associated with significantly lower likelihood of response to intensive chemotherapy (OR: 41 *vs* 86%, p<0.001; CR: 33 *vs* 75%, p<0.001).

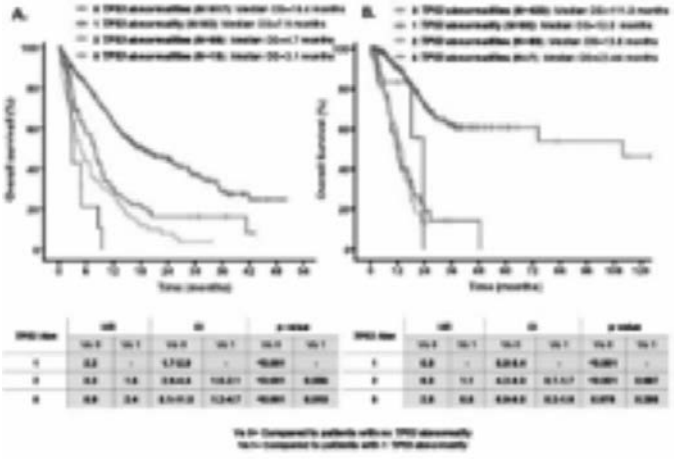

Figure 1.

Summary/Conclusions: Presence of multiple *TP53* abnormalities can be observed in up to 13% patients with AML and MDS. Second *TP53* abnormalities more commonly involve *TP53* deletions with additional *TP53* mutations being less common and generally mutually exclusive with *TP53* deletions. The number of *TP53* abnormalities impacts the survival of patients with AML but not that of patients with MDS. Presence and number of *TP53* mutations do not seem to impact response to HMAs but are associated with lower responses to chemotherapy.

P201

VADASTUXIMAB TALIRINE PLUS HYPOMETHYLATING AGENTS: A WELL-TOLERATED REGIMEN WITH HIGH REMISSION RATE IN FRONTLINE OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA

F. Ravandi[1,*], A. Stein[2], H. Erba[3], J. Lancet[4], E. Stein[5], S. Faderl[6], R. Walter[7], A. Advani[8], D. DeAngelo[9], T. Kovacsovics[10], A. Jillella[11], D. Bixby[12], M. Levy[13], M. O'Meara[14], P. Ho[14], A. Fathi[15]
[1]Department of Leukemia, MD Anderson, Houston, [2]Gehr Family Center for Leukemia Research, City of Hope, Duarte, [3]Hematologic Malignancy Program, University of Alabama at Birmingham, Birmingham, [4]Malignant Hematology, Moffitt Cancer Center, Tampa, [5]Hematology, Memorial Sloan Kettering, New York City, [6]Leukemia, John Theurer Cancer Center, Hackensack, [7]Hematology, Fred Hutchinson Cancer Center, Seattle, [8]Hematology and Oncology, Cleveland Clinic, Cleveland, [9]Hematology and Oncology, Dana-Farber Cancer Institute, Boston, [10]Hematology and Oncology, Huntsman Cancer Institute, Salt Lake City, [11]Hematology and Oncology, Winship Cancer Institute, Atlanta, [12]Hematology and Oncology, University of Michigan Comprehensive Cancer Center, Ann Arbor, [13]Hematology and Oncology, Baylor Charles A. Sammons Cancer Center, Dallas, [14]Clinical Development, Seattle Genetics, Inc., Bothell, [15]Hematology and Oncology, Massachusetts General Hospital Cancer Center, Boston, United States

Background: Treatment of AML among the elderly is challenging. HMAs are commonly used, but yield suboptimal response rates and modest survival. Deep remissions are difficult to achieve; in a study of MRD response by flow cytometry in patients treated with single-agent HMA therapy at MD Anderson Cancer Center, only 13/58 (22%) responding patients achieved minimal residual disease (MRD) negativity (F Ravandi, MD, unpublished data, Jan2017). Vadastuximab talirine (SGN-CD33A; 33A) is a CD33-directed antibody conjugated to 2 molecules of a pyrrolobenzodiazepine (PBD) dimer. Upon binding, 33A is internalized and transported to the lysosomes where PBD dimer is released via proteolytic cleavage of the linker, crosslinking DNA, and leading to cell death.
Aims: A cohort in a phase 1 study (NCT01902329) was designed to evaluate the safety, tolerability, PK, and antileukemic activity of 33A in combination with an HMA.
Methods: Eligible patients (ECOG status 0-1) had previously untreated CD33-positive AML. One dose of 33A (10 mcg/kg) was administered outpatient IV every 4 weeks on the last day of HMA (azacitidine or decitabine [5-day regimen], standard dosing). CRi required either platelet count of ≥100,000/μL or neutrophils of ≥1,000/μL (Cheson 2003). MRD was measured by multiparameter flow cytometry.
Results: Fifty-three patients (median age 75 years [range, 60-87]) were treated with 33A+HMA. Patients had adverse (38%) or intermediate (62%) cytogenetics (per MRC); patients were either unfit for (40; 75%) or declined (13; 25%) intensive therapy. The median treatment duration is currently 19.3 weeks (range, 2-86) with 8 patients still on treatment; no DLTs were reported. Adverse events (AEs) ≥Grade 3 reported in ≥15% of patients were thrombocytopenia (55%), febrile neutropenia (49%), anemia (46%), neutropenia (42%), pneumonia (19%), and leukopenia (17%); no ≥Grade 4 bleeding events were observed. Treatment-emergent (TE) liver lab elevations (≥Grade 3) were rare: ALT (8%), AST (2%), and total bilirubin (2%). Other non-heme TEAEs reported in >25% of patients regardless of relationship to study treatment were fatigue (60%), nausea (49%), constipation (43%), peripheral edema (42%), decreased appetite (40%), dyspnea (34%), pyrexia (32%), diarrhea, vomiting (28% each), and dizziness (26%). Thirty- and 60-day mortality rates were 2% and 8%, respectively, with no treatment-related deaths reported. A total of 39% (103/263) of doses were delayed due to AEs mostly from myelosuppression (neutropenia 18%, thrombocytopenia 7%, and febrile neutropenia 3%). High remission rates (37/49 [76%] CR+CRi) were maintained across adverse disease subsets including adverse cytogenetics (16/18, 89%), *TP53*-mutated (6/7, 86%), secondary AML (18/22, 82%), and age ≥75 years (18/26, 69%). Of all responding patients, 19/37 (51%) achieved MRD negativity. Two patients went on to subsequent allo-HSCT, and no SOS/VOD was observed. The median relapse-free survival was 9.1 months (range, 0.1-19.4+) and OS continues to evolve with 15 patients (28%) alive (11.3 month median follow-up) (Figure 1).
Summary/Conclusions: 33A+HMA is well tolerated with a safety profile consistent with on-target myelosuppression. The CR+CRi rate of 76% and low early mortality in older AML patients with poor risk factors is particularly encouraging, and activity appears markedly improved compared to the historical experience of HMA monotherapy. The MRD clearance rate among responding patients who received 33A+HMA is higher than the rate observed with single

agent HMAs. Survival data are evolving and compare favorably to historical controls. CASCADE, a phase 3 trial investigating 33A+HMA v. HMA alone in older AML patients, is enrolling (NCT02785900).

[1]Hospital de la Santa Creu i Sant Pau, [2]Hospital Clinic de Barcelona, [3]Hospital Germans Trias i Pujol , [4]Hospital Duran i Reynals, Barcelona, [5]Hospital Josep TRueta, Girona, [6]Hospital Joan XXIII, Tarragona, [7]Hospital Clínico de Málaga, Málaga, [8]Hospital de la Vall d'Hebrón, Barcelona, [9]Hospital Arnau de Vilanova , Lleida, [10]Hospital Mutua Terrassa, Terrassa, [11]Hospital del Mar, Barcelona, [12]Hospital Son Llàtzer, Palma de Mallorca, [13]Hospital Son Espases, Mallorca, [14]Hospital Germans Trias i Pujol, Barceloan, Spain

Background: Acute myeloid leukemia (AML) with intermediate-risk (IR) cytogenetics includes a substantial proportion of patients with favorable molecular profile (FMP); in which AML cells harbor the NPM1 mutation or CEBPA biallelic mutation without internal tandem duplication of the FLT3 gene (FLT3-ITD). The role of allogeneic hematopoietic transplantation (allo-HCT) in first complete remission (CR) in these patients remains controversial.

Aims: To analyze the results and prognostic factors of IR-FMP AML patients in a large series of patients treated by the Spanish CETLAM group.

Methods: Patients with primary AML diagnosed at 19 institutions from the Spanish CETLAM group and treated between 2003 and 2017. Induction chemotherapy included idarubicin and cytarabine (standard or intermediate-dose) in all cases, consolidation with intermediate or high-dose cytarabine (HDAC) and, depending on the protocol, additional HDAC, autologous or allogeneic hematopoietic transplantation.

Results: Two-hundred twenty-one patients were analyzed. Median age of the series was 54 years (range 18 to 72). 152 patients had an age up to 60 years and 69 (31%) were older. Median WBC count was 19x10e9/l (range 0.55-282). One-hundred eighty-two patients had a normal karyotype and it was abnormal in 34 (5 patients no metaphases). One hundred ninety-one patients had NPM1 mutated and FLT3-ITD wild type (NPM1+/FLT3-ITD-) and 30 CEBPα biallelic mut /FLT3-ITD wild type (CEBPα+/FLT3-ITD-). There were no significant differences in the main clinical or biological parameters in these two groups. The CR rate in the overall group was very high (92%) without significant differences between the two molecular groups. Chemo-resistance was observed in only 2 patients of the NPM1+/FLT3-ITD- group (1%). Death during induction was observed in 16 patients (7%), all of them with NPM1+/FLT3-ITD-. Induction results according to age were similar in both groups. Event-free survival and overall survival are reported at 8 years and were 52±8% and 70±4%, respectively. In univariate comparisons, better EFS and OS was observed in CEBPα+/FLT3-ITD- patients compared to those with NPM1+/FLT3-ITD- (p=0.03 and p= 0.02, respectively) . When analyzing post-remission treatment, patients treated with HDAC only had an excellent prognosis, even better than those receiving an autologous or allogeneic transplantation. One patient died in CR in the HDAC group, another in the autologous transplant group and 7 in the allo-HCT group (p<0001). In multivariate analysis of pretransplant characteristics, age up to 60 years and CEBPα+/FLT3-ITD- associated to improved EFS (RR=0.42) and OS (RR=0.29). Interestingly, in a subgroup of 123 patients with data on MRD after consolidation chemotherapy (flow citometry, cut-off: 0.12%), positivity was associated with worse EFS (0.02). Despite age was a prognostic factor, patients older than 60 years with IR-FMP AML had remarkable EFS of 36±3% and OS 54±10% at 8 years (Figure 1).

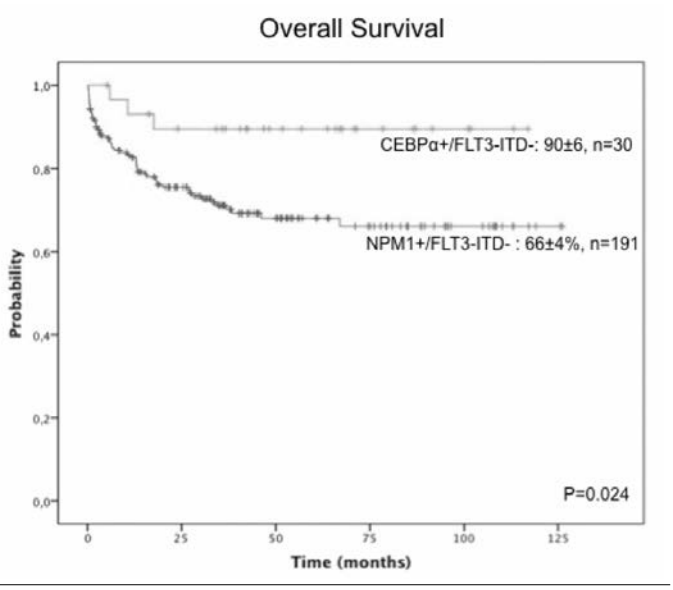

Figure 1.

Summary/Conclusions: Patients with primary AML, IR cytogenetics and FMP have a good outcome. Best results are achieved in patients with CEBPα+/FLT3-ITD-, particularly if age is up to 60 years. In this subset, OS at 8 years is 96±7%, comparable to current results achieved in acute promyelocytic leukemia. Patients above 60 years treated intensively may achieve a long term survival of more than 50%. Chemotherapy without subsequent transplantation is a valid option. MRD monitoring after treatment has to be taken into account since in the subset of patients analyzed this vas an independent prognostic factor for EFS.

P203

GMI-1271, A POTENT E-SELECTIN ANTAGONIST, COMBINED WITH INDUCTION CHEMOTHERAPY IN ELDERLY PATIENTS WITH UNTREATED AML: A NOVEL, WELL-TOLERATED REGIMEN WITH A HIGH REMISSION RATE

D.J. DeAngelo[1,*], B.A. Jonas[2], D.L. Bixby[3], P.S. Becker[4], M.E. O'Dwyer[5], A.S. Advani[6], P. Marlton[7], J.L. Magnani[8], H. Thackray[8], J.L. Liesveld[9]

[1]Dana-Farber Cancer Institute, Boston, [2]UC Davis Comprehensive Cancer Center, Sacramento, [3]University of Michigan Comprehensive Cancer Center, Ann Arbor, [4]Fred Hutchinson Cancer Research Center, U of Washington, Seattle, United States, [5]National University of Ireland, Galway, Ireland, [6]Cleveland Clinic Taussig Cancer Institute, Cleveland, United States, [7]Princess Alexandra Hospital, Brisbane, Australia, [8]GlycoMimetics, Inc., Rockville, [9]Univ of Rochester James P Wilmut Cancer Ctr, Rochester, United States

Background: The outcomes for elderly patients (pts) with acute myeloid leukemia (AML) remain poor due to limited tolerance of intensive cytotoxic chemotherapy and low response rate, therefore newer and less toxic therapies are urgently needed. The binding of E-selectin (E-sel), an adhesion molecule expressed in the vasculature of the bone marrow, to the leukemic cell surface activates survival pathways and promotes chemotherapy resistance. GMI-1271, a novel E-sel antagonist, disrupts these survival pathways and enhances chemotherapy response (Becker ASH 2013; Winkler ASH 2014). Protection from common toxicities (neutropenia and mucositis) has also been observed in preclinical models, affording survival benefit (Winkler ASH 2013). Additionally, preclinical toxicology studies have indicated a benign safety profile. We report interim Phase 2 data for GMI-1271 plus anthracycline-based induction chemotherapy in elderly untreated pts with AML.

Aims: A Phase 2 open label trial of patients ≥60 yrs with untreated AML assessed safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and antileukemic activity of GMI-1271.

Methods: Eligible pts had ECOG 0-2, WBC <40K/uL, no active CNS disease, and adequate renal and hepatic function. Prior treatment of MDS was allowed. GMI-1271 (10 mg/kg) was given 24 hrs prior, then every 12 hrs during and for 48 hrs post induction with infusional cytarabine and idarubicin (7+3). Two cycles of induction were allowed and responders could receive consolidation with GMI-1271 plus intermediate dose cytarabine. Dose-limiting toxicity (DLT), defined as myelosuppression in the absence of disease or related Grade 3 (Gr) non-hematologic toxicity beyond day 42, was assessed in the first 3 pts. Baseline E-selectin ligand expression on leukemic blasts in the bone marrow (CD45/SSC by flow) is reported.

Results: 24 pts have been enrolled to date and 17 are evaluable for response. The median age was 68 years (range, 60-79) with 58% male pts, and 25% with high-risk cytogenetics (by SWOG). 50% (12/24) were pts with secondary AML (sAML), half of whom had prior hypomethylating therapy (50%; 6/12), . This study had a rolling safety run-in and the first 3 pts had no DLT, allowing enrollment to proceed. Common Gr 3/4 AEs included febrile neutropenia (47%), pneumonia (20%), pulmonary edema (13%) and non-fatal respiratory failure (13%). 2 pts died of sepsis within 60 days. The remission rate (CR/CRi) was 12/17 (71%). CR/CRi rate was 75% for pts with *de novo* disease and 67% for pts with sAML. The PK profile in this elderly population was consistent with that of younger adults (median age <60 years) with relapsed or refractory AML in Phase 1 (DeAngelo, EHA 2016); no accumulation or evidence of drug-drug interactions were apparent. The median E-sel ligand expression at baseline was 29% (range, 2-67%) of blasts in the bone marrow.

Summary/Conclusions: The addition of a novel E-selectin antagonist, GMI-1271, to anthracycline-based induction chemotherapy in untreated elderly pts with AML, including patients with secondary AML, demonstrates a high remission rate with acceptable side effect profile resulting in low induction mortality. This study compares favorably to previous studies (Lancet, ASCO 2016). E-selectin ligand was expressed on leukemic blasts in the majority of pts, therefore supporting its relevance as a target. A randomized trial is being planned.

P204

A PHASE 2 STUDY OF GLASDEGIB (PF-04449913) IN COMBINATION WITH CYTARABINE AND DAUNORUBICIN IN UNTREATED PATIENTS WITH ACUTE MYELOID LEUKEMIA OR HIGH-RISK MYELODYSPLASTIC SYNDROME

J.E. Cortes[1,*], B.D. Smith[2], E.S. Wang[3], A. Merchant[4], V.G. Oehler[5], M. Arellano[6], D.J. DeAngelo[7], D.A. Pollyea[8], W.W. Ma[9], M. Zeremski[10], M.N. Shaik[10], A. O'Connell[11], G. Chan[11], M.A. Schroeder[12]

[1]University of Texas, MD Anderson Cancer Center, Houston, TX, [2]Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD, [3]Roswell Park Cancer Institute, Buffalo, NY, [4]University of Southern California Cancer Center, Los Angeles, [5]Fred Hutchinson Cancer Research Center, Seattle, WA, [6]Emory University School of Medicine, Atlanta, GA, [7]Dana-Farber Cancer Institute, Boston, MA, [8]University of Colorado Cancer Center, Aurora, CO, [9]Pfizer Oncology, New York, NY, [10]Pfizer Oncology, La Jolla, CA, [11]Pfizer Oncology, Collegeville, PA, [12]Washington University Medical School, Saint Louis, MO, United States

Background: Glasdegib, a selective, once-daily (QD), oral Smoothened (SMO) inhibitor, demonstrated significant improvement in overall survival (OS) when used in combination with low-dose cytarabine (LDAC) *vs* LDAC alone in a randomized (2:1) open-label trial in 132 patients (pts) not suitable for induction chemotherapy (ICT). Preclinical studies showed that glasdegib limits leukemia stem cell proliferation and provided evidence of glasdegib synergy with chemotherapy.

Aims: Primary objective of this open-label, single-arm Ph 2 study (NCT01546038) was to determine complete remission (CR) rate with glasdegib in combination with cytarabine and daunorubicin in untreated AML or high-risk MDS pts suitable for ICT. OS was the key secondary endpoint.

Methods: Pts suitable for ICT (ECOG PS 0-1, creatinine ≤1.3 mg/dL, no severe cardiac disease) gave informed consent and received glasdegib 100 mg QD from day -3 in combination with cytarabine 100 mg/m^2 CI for 7 days and daunorubicin 60 mg/m^2 IV for 3 days, followed by 2-4 consolidation cycles (cytarabine 1 g/m^2 Q12 hrs on days 1, 3, 5). Maintenance (up to 6 months) included glasdegib 100 mg QD. Pts were assessed for efficacy, safety and tolerability.

Results: All Pts: As of 1 Dec 2016, 71 pts (66 AML, 5 MDS) were enrolled and 69 pts received glasdegib and ICT (2 pts not treated due to ineligibility). Among AML pts (47 de-novo; 19 secondary), 20% had favorable, 32% intermediate (int)-I, 21% int-II and 26% adverse cytogenetic abnormalities (1 pt not assessed). Among MDS pts (5 de-novo), 20% had good, 40% int and 40% poor risk cytogenetic abnormalities. Median age was 64 (27-75) years. Median treatment duration was 48 (10-502) days. The most common NCI-CTC v4.0 grade 3-4, non-hematologic all-cause adverse events (AEs) included: hypokalemia (13%), hyponatremia (11.6%) and hypertension (10.1%). Grade 5 AEs within 28 days from last dose (5 pts, 7.2%) included pneumonia, sepsis, septic shock (1 pt each) and disease progression (2 pts). The observed steady-state plasma exposures for glasdegib were as expected at the 100 mg dose level. Based on investigator's assessment, CR was 41% (80% CI 33.2-47.9) and CR/CRi was 49%. CR for good/int. risk pts (n=49) was 49% and for poor risk pts (n=19) 21%. Forty-one (59%) pts died (33 [48%] due to disease progression) with median follow up of 30.1 months; 24 (35%) remain in follow up. The median OS (mOS) was 14.9 months (80% CI 13.4-19.3); 16.3 months for AML pts and 13.0 months for MDS pts. Twenty-three (33%) pts received a transplant and mOS censored for transplant was 17.7 months. AML Pts >60 yrs: The mOS for 44 AML pts age >60 yrs is presented in the Table 1, in the context of historical control.

Table 1. mOS in Pts >60 Yrs Stratified by European Leukemia Net (ELN) Risk Criteria

Risk Group	ICT (Historical Röllig et al, 2011) months	ICT + Glasdegib (n=44*) months	Increase in mOS (%) (29 events)
Favorable	14.6	Not reached (n=9)	Not estimable
Int-1	9.5	15.7 (n=12)	65.3
Int-2	9.2	13.4 (n=12)	45.7
Adverse	4.8	8.5 (n=10)	77.1

*1 pt was not classifiable by ELN risk.

Summary/Conclusions: Although the CR rates do not appear to be higher than those reported historically for AML pts receiving ICT, the mOS for AML pts >60 yrs stratified by subgroup compares favorably by adding glasdegib. It is possible that this is a result of the effect of glasdegib on the leukemia stem cells. The combination of glasdegib with ICT was well tolerated, with a safety profile consistent with that in AML pts receiving standard ICT. Further studies are warranted.

P205

CM942 IS A NEW SMALL MOLECULE THAT TARGETS SET-PP2A INTERACTION AND INHIBITS GROWTH OF ACUTE MYELOID LEUKEMIA CELLS

P. García-Ramírez[1,*], C. Vicente[2], E. Arriazu[3], M. Nerea[3], J. Rifón[4], A. Domínguez[3], A. Alonso[2], I. Vázquez[3], M.J. Calasanz[2], M.C. Mateos[1], M.D. Odero[2]

[1]Hematology, Complejo Hospitalario de Navarra, [2]University of Navarra, [3]CIMA, University of Navarra, [4]Clinica University of Navarra, Pamplona, Spain

Background: Acute myeloid leukemia (AML) is a heterogeneous malignant disorder of hematopoietic progenitor cells in which several genetic and epigenetic aberrations have been described. Nevertheless, outcome for most patients is poor, and it is necessary to develop more effective treatment strategies. Our group showed that the inactivation of the tumor suppressor PP2A is a recurrent event in AML, and that overexpression of SET, an endogenous inhibitor of PP2A, is a poor prognostic factor in this disease. Furthermore, the anticancer activity of FTY720, a PP2A-activating drug (PAD), depends on its interaction with SET. FTY720 is a relatively nontoxic drug currently used in patients with relapsing multiple sclerosis; however, this drug cannot be used in cancer patients due to its toxicity at the needed anti-neoplastic dose. Therefore, investigation of alternative agents for reactivation of PP2A is warranted.

Aims: To test the efficacy of CM942, a FTY720 analogue, on AML cell lines and primary patient samples, and investigate its mechanism of action.

Methods: AML cell lines and 29 de novo AML samples were analyzed by treatment with FTY720 and CM942, MTS (viability), apoptosis, cell cycle and PP2A activity assays, and western blot.

Results: CM942 exhibited notable cytotoxicity on all human AML cell lines with SET overexpression (n=10). By using phosphatase assays we confirmed that CM942 treatment activated PP2A on cell lines, similarly to FTY720. Immunoprecipitation of PP2Ac in untreated cells confirmed that SET interacts with PP2Ac, and that treatment with CM942 effectively disrupted this association. Furthermore, CM942 had a caspase-dependent pro-apoptotic effect, and decreased phosphorylation of the PP2A target ERK1/2. Microarray data from vehicle-treated and CM942-treated HL-60 cells showed a high correlation between the gene expression profiles of the samples. This analysis identified up-regulated and down-regulated genetic pathways by treatment with CM942, providing mechanistic insights into the anti-tumor mechanism of this small molecule. Our analyses in primary AML samples showed that 7 out of 29 (24%) samples treated with CM942 had a significant reduction in proliferation. By western blot analyses we found that those patients responding to CM942 treatment had SET overexpression. Of note, treatment of peripheral blood mononuclear cells from healthy donors with CM942 had no effects on cell viability. Therefore, although FTY720 and CM942 have similar effects inhibiting cellular proliferation, CM942 was less toxic when assayed on normal peripheral blood cells.

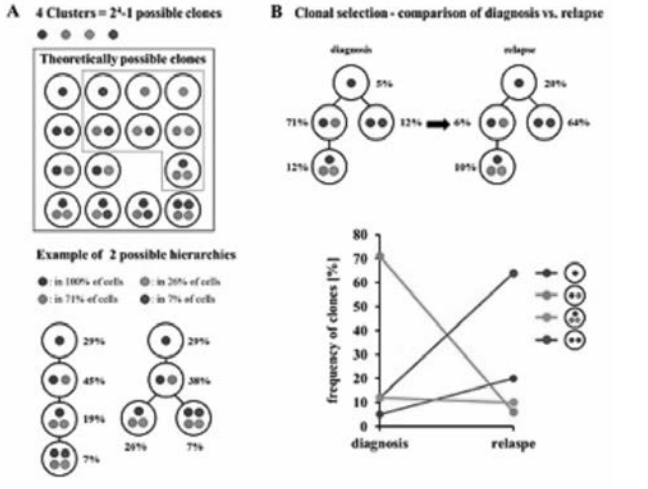
Summary/Conclusions: CM942 inhibits growth of AML cells in both cell lines and primary patient samples, exerting its antileukemic effects through reactivation of PP2A activity. Although treatment with FTY720 was somewhat more effective than CM942 in primary samples of AML, fewer cytotoxic effects were observed after CM942 treatment in peripheral blood from healthy donors. Further experiments would be necessary to confirm the *in vivo* antitumor activity of CM942 in AML models. New compounds have been developed for the treatment of AML, although few have been translated into clinical practice; nevertheless, it is unlikely that any of these compounds, when used as single agents, will cure the disease, which suggests the need for combinatorial therapy. Our results indicate that PADs may be a valid therapeutic option for AML, especially for treating leukemias characterized by SET-dependent inactivation of PP2A.

P206

CLONAL HETEROGENEITY IN LEUKEMIC STEM CELLS FROM PATIENTS WITH ACUTE MYELOID LEUKEMIA

L. Manta[1,*], B. Saeed[1], L. Poisa Beiro[1], P. Pyl[2], T. Stiehl[3], K. Barth-Miesala[1], V. Eckstein[1], W. Huber[2], A.D. Ho[1], C. Lutz[1]
[1]Department of Medicine V, University of Heidelberg, [2]Multi-omics and statistical computing, European Molecular Biology Laboratory , [3]4Interdisciplinary Center for Scientific Computing & Institute of Applied Mathematics, University of Heidelberg, Heidelberg, Germany

Background: Clonal heterogeneity occurs in many cancers, including Acute Myeloid Leukemia (AML). In cases of relapse, chemotherapy has triggered clonal selection with minor or evolved sub-clones driving relapse. A better understanding of the underlying clonal architecture, the extent of genetic heterogeneity and its response to therapy is necessary to better understand mechanisms of therapy escape and relapse.
Aims: In this study we aim to define the clonal architecture of AML during the course of therapy and in leukemia propagating cells.
Methods: We sequenced 12 AML samples at the time of diagnosis and in one case also at the time of relapse with at least 80% blasts per sample. 6/12 patients displayed a normal karyotype while the other 6 patients showed various cytogenetic abnormalities (inversion 16 (2), trisomy 8 (1), add(19)(p13.3) (1), complex aberrant karyotype (2)). Whole-exome sequencing (WES) was performed with the appropriate germ line controls. WES data were clustered using empirical Bayesian clustering.
Results: WES identified more than 3000 variants in total. By setting distinct filtration criteria (20% allele frequency (AF), ≥10 reads coverage, ≥2 reads support of the detected variant, SIFT-score <0,05 and GMAF <5%) 64 leukemia specific mutations were detected (1-18 mutations/AML). As expected, these included recurrently mutated genes like DNMT3A (in 4 patients), IDH1 and 2 (each in one patient), KIT and NRAS (both in 2 patients). Categorization of identified mutations showed that these mutations affected genes involved in various cellular processes including transcriptional regulation (15), cell differentiation (6), cell cycling (5), apoptosis/survival signals (5), proliferation (3), cell growth (3) and splicing (3). Empirical Bayesian clustering of all detected variants according to their respective AF resulted in 2-5 different clusters per AML. Based on this cluster analysis we were able to predict the founding cluster/clone. Assuming that most of the mutations are heterozygous and considering the blast percentage at diagnosis, mutations of the biggest clusters are present in every cancer cell and the mutations of the smaller clusters in proportionately smaller fractions. Based on the clustering information we were able to model the potential clonal hierarchies. Using a combinatorial approach, clonal modelling can identify which theoretically existing clones (2^n-1; n= number of clusters) were present at the time of diagnosis and in which order they evolved (Figure 1). Through comparison of clusters from diagnosis and relapse clonal selection can also be detected and via modelling the most likely clonal architectures can be identified. By assigning our 64 identified leukemia-specific mutations to the defined clusters we can now track the different clusters/clones in phenotypically distinct subpopulations and during xenotransplantations by targeted sequencing. An update of this analysis will be presented at EHA.



Modelling of potential clonal architectures according to clustering data

A) Example of the clonal make-up in an AML sample with 4 detectable clusters. In theory 2^n-1 clones are possible. In the case of 4 clusters 15 combinations are possible. If the purple cluster contains the founding mutations - clones in the dotted area are therefore unlikely to occur, since this cluster is present in every cancer cell. On the bottom two possible clonal hierarchies are shown that are based on the presented cluster frequencies.

B) Through comparison of clusters from diagnosis and relapse we can detect clonal selection and via modelling we can identify the most likely clonal architectures of both time points. By comparing the modelled clonal hierarchies from diagnosis and relapse (one example is shown) we can evaluate which model fits best to explain the clonal make up of both time points allowing an estimation of the clonal complexities.

Figure 1.

Summary/Conclusions: WES can identify leukemia specific mutations that are involved in various cellular functions including mutations that have been shown to be recurrently mutated in AML like DNMT3A. Sequencing data can also be used in combination with mathematical modelling approaches to reconstruct the clonal architecture of AML at the time of diagnosis and relapse allowing estimations of the clonal complexity at these time points.

P207

TREATMENT OF PRACINOSTAT AND AZACITIDINE IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML): CORRELATION BETWEEN MUTATION CLEARANCE AND CLINICAL RESPONSE

K. Takahashi[1,*], Y. Abaza[1], F. Wang[1], C. Gumbs[1], S. Xingzhi[1], A. Futreal[1], E. Atallah[2], B. Medeiros[3], S. Khaled[4], M. Arellano[5], M. Patnaik[6], E. Palmesino[7], G. Garcia-Manero[1]
[1]University of Texas MD Anderson Cancer Center, Houston, [2]Medical College of Wisconsin, Milwaukee, [3]Stanford University, Stanford, [4]City of Hope, Duarte, [5]Emory University School of Medicine, Atlanta, [6]Mayo Clinic, Rochester, United States, [7]Helsinn, Pazzallo, Switzerland

Background: In a phase 2 study of 50 elderly patients (≥65 years) with AML who were not eligible for intensive chemotherapy, treatment with the investigational HDAC inhibitor pracinostat+azacitidine (AZA) was well tolerated and led to 42% complete remission (CR) rate and a median overall survival (OS) of 19.1 months (Blood 2016; 128:100). Responses were durable (median CR+CRi 17.2 months), blast clearance was rapid (median 8 weeks), and maximum clinical benefit required prolonged therapy (>6 months) in some patients.
Aims: Our aim was to understand the impact of somatic mutations and their clearance on disease response and survival outcomes in AML patients treated with pracinostat+AZA.
Methods: 88 samples from 41 study patients were sequenced. Pre-treatment samples were available for analysis from all 41 patients, and a median of 3 longitudinal samples were analyzed from 19 patients between Cycle 2 and 9. Leukemia mutations were detected by SureSelect targeted capture exon sequencing (Agilent) of 295 genes that are recurrently mutated in hematologic malignancies (median coverage 507x [range: 111-777x]). Longitudinal mutation clearance was analyzed by tracking variant allele frequency (VAF). Informed consent was obtained from all patients.
Results: At baseline, 96 mutations in 28 genes were detected in 38 (93%) patients, with the most frequent being in *SRSF2* (27%), *DNMT3A* (20%), *IDH2* (17%), *RUNX1* (17%), and *TET2* (17%). The median number of mutations detected per patient was 2 (range: 0-6). Among the 33 patients with evaluable treatment response, CR was observed in 13 (39%) patients. The rate of CR was significantly higher in patients with mutations in *NPM1* or in one of the DNA methylation pathway genes, while patients with *TP53* mutation had a trend for poor CR (Table 1). The median follow up duration of the 41 patients was 23.8 months (95% CI: 20.4-27.1 months) with median OS of 18.1 months (95% CI: 10.1-26.1 months), patients with *CEBPA* mutation had a trend toward better OS, whereas patients with *NF1* mutation had significantly worse OS (Table). Considering mutations associated with AML ontogeny (Lindsley RC, Blood 2015;125:1367-76), median OS was 17.7 months in 20 patients with mutations typically associated with secondary AML and 18.1 months in 18 patients with mutations typically associated with de novo AML. Among the 19 patients whose longitudinal specimens were analyzed, 10 achieved CR. Of those 10 patients, 9 (90%) had persistently detectable mutations in their bone marrow at the time of CR, however, in 7 of them, continued exposure to pracinostat+AZA lowered the VAF or cleared residual mutations. Mutations in genes associated with DNA methylation, RNA splicing, clonal hematopoiesis of indeterminate potential (CHIP), and receptor tyrosine kinase (RTK) pathways had poor clearance of mutation, while transcription factors or cohesin had better clearance with pracinostat+AZA treatment. In 2 patients, relapsed samples were sequenced and showed re-expansion of the founder clone.

Table 1.

	CR rate (%)		
Gene; n (%)	**Mutated**	**Wild-type**	**P value**
NPM1; 6 (15)	83	30	0.025

CEBPA; 3 (7)	100	33	0.052
TET2 ; 5 (12)	80	32	0.066
RAD21; 3 (7)	100	33	0.052
TP53; 5 (12)	0	46	0.065
	OS (months)		
CEBPA; 3 (7)	Not reached	14.8	0.061
RUNX1; 6 (15)	7.9	18.1	0.078
NF1; 3 (7)	3.0	19	0.005

* *DNTM3A, IDH1, IDH2*, or *TET2*

Summary/Conclusions: Mutations in *NPM1*, and DNA methylation pathway were associated with a better response to pracinostat+AZA, while *TP53* mutation was associated with a trend toward poor response. Persistent mutation at the time of CR suggests residual preleukemic clonal hematopoiesis in this elderly population. Benefit of prolonged exposure to pracinostat+AZA was also confirmed at molecular level where continued decline of mutation VAF was seen after achieving CR.

Acute myeloid leukemia - Clinical 3

P208

STABLE DISEASE WITH HEMATOLOGIC IMPROVEMENT IS CLINICALLY MEANINGFUL FOR OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA TREATED WITH AZACITIDINE

A.C. Schuh[1,*], H. Döhner[2], J.F. Seymour[3,4], P. Turlure[5], C. Junghanss[6], A. MacWhannell[7], N. Tu[8], S. Songer[8], C. Beach[8], H. Dombret[9]
[1]Princess Margaret Cancer Centre/University Health Network, Toronto, Canada, [2]Universitätsklinikum Ulm, Ulm, Germany, [3]Peter MacCallum Cancer Centre, Melbourne, [4]University of Melbourne, Parkville, Australia, [5]Centre Hospitalier Universitaire de Limoges, Limoges, France, [6]Universitätsmedizin Rostock, Rostock, Germany, [7]The Royal Wolverhampton Hospitals NHS Trust, Wolverhampton, United Kingdom, [8]Celgene Corporation, Summit, United States, [9]Hôpital Saint Louis- Institut Universitaire d'Hématologie, Paris, France

Background: Effects on overall survival (OS) are of primary importance when evaluating AML treatments (Tx). Though complete remission (CR) rates are lower with azacitidine (AZA) than with intensive chemotherapy (IC), OS is similar with AZA and IC (Dombret *et al.*, *Blood*, 2015). The 2017 European LeukemiaNet (ELN) recommendations acknowledge that hypomethylating agents, including AZA, may alter the natural course of AML in some patients (pts) who do not achieve CR (Döhner *et al.*, *Blood*, 2017). According to IWG criteria for AML (Cheson *et al.*, *J Clin Oncol*, 2003), stable disease (SD) is considered non-response to Tx. Yet AML is a progressive disease; potentially, stable health status may reflect delayed disease progression and result in improved OS.
Aims: This *post hoc* analysis evaluated OS outcomes among older pts with AML treated with AZA or conventional care regimens (CCR) who maintained SD, with or without hematologic improvement (HI), in the phase 3 AZA-AML-001 study.
Methods: Pts aged ≥65 years with AML (>30% marrow blasts), ECOG PS score ≤2, NCCN-defined intermediate- or poor-risk cytogenetics, and WBC count ≤15x10^9/L received AZA (75mg/m^2 x7 days [d]/28d cycle) or a CCR (IC [standard 7+3 regimen], low-dose cytarabine [20mg BID x 10d/28d cycle], or best supportive care). OS was assessed using Kaplan-Meier methods for pts with SD at 2-, 4-, and 6-month landmarks. SD was protocol-defined as the absence of an IWG-defined AML response and no progressive disease (PD), whether or not HI was attained. Pts with SD could have had an IWG-defined response or PD at any time other than at the specified landmarks. OS was also evaluated in pts with HI as their best response; attainment of HI must have begun on or before, and been sustained past, each landmark, and lasted for ≥56 consecutive days.

Table 1.

Survival among patients with Stable Disease, with or without hematologic improvement, at 2-month study landmarks

Landmark	SD and HI status	N		Median OS, months (95%CI)		Difference in Median OS, AZA vs CCR	K-M Estimated 1-Year survival		Difference in 1-year survival, AZA vs CCR (95%CI)
		AZA	CCR	AZA	CCR		AZA	CCR	
2 months	SD Overall	103	67	13.6 (12.0, 15.4)	11.1 (7.9, 14.1)	+2.5 months	59.2%	44.4%	+14.8% (-0.5%, 30.1%)
	SD/HI+	19	7	17.0 (6.9, 22.3)	12.2 (4.9, NR)	+4.8 months	63.2%	53.6%	+9.6% (-35.3%, 54.5%)
	SD/HI-	84	60	13.3 (11.5, 15.3)	11.1 (7.5, 14.1)	+2.2 months	58.3%	43.3%	+15.0% (-1.4%, 31.4%)
	Difference, HI+ vs HI-			+3.7 months	+1.1 months		+4.9%	+10.3%

	SD/HI+	25	7	20.8 (15.3, NR)	15.1 (9.1, NR)	+5.7 months	84.0%	51.4%	+32.6% (-9.9%, 75.0%)
	SD/HI-	45	35	12.9 (10.4, 14.3)	12.2 (10.0, 14.5)	+0.7 months	57.8%	51.4%	+6.3% (-15.6%, 28.3%)
	Difference, HI+ vs HI-			+7.9 months	+2.9 months		+26.2%	0%	

95%CI, 95% confidence interval; AZA, azacitidine; CCR, conventional care regimens; K-M, Kaplan-Meier; NR, not reached

Results: Median OS for all SD pts was 2.1-2.5 months longer with AZA *vs* CCR, and estimated 1-year survival was ~15% higher at each landmark in the AZA arm (Table 1). Hazard ratios for OS among all SD pts treated with AZA *vs* CCR ranged from 0.81–0.88. Median OS among pts with SD and no HI ranged from 12.6–13.3 months in the AZA arm and from 11.1-12.2 months in the CCR arm. Within Tx arms, AZA-treated pts with HI had meaningfully improved OS at all landmarks, ranging from 3.7 to 7.9 months longer than OS for pts without HI (Table 1). In contrast, HI attained with CCR did not largely influence OS; differences between pts who attained HI *vs* no HI ranged from -0.2 to 2.9 months. Median durations of HI in the AZA *vs* CCR arms, respectively, were 183 *vs* 166

days at 2 months, 176 *vs* 148 days at 4 months, and 176 *vs* 138 days at 6 months. Estimated 1-year survival within the AZA arm was 4.9%–27.4% greater for pts with HI than for pts with no HI, but for CCR-treated pts with HI, 1-year survival was 0%–10.3% greater. Between Tx arms, 1-year survival with AZA in pts with HI was 9.6%–33.3% greater than for CCR-treated pts with HI.
Summary/Conclusions: Maintaining SD during AZA or CCR Tx is associated with relatively favorable OS outcomes, as median OS in pts with SD exceeded that for all pts in the AZA-AML-001 trial (10.4 months with AZA *vs* 6.5 months with CCR; Dombret *et al*., *Blood*, 2015). Pts with SD who also attained HI during early AZA Tx had meaningfully improved OS, whereas similar CCR-treated pts did not, suggesting that HI with AZA is qualitatively different from HI with CCR. The prognostic relevance of HI in AML requires further study.

P209

A RANDOMIZED PHASE II STUDY OF IDARUBICIN AND CYTARABINE WITH EITHER CLOFARABINE OR FLUDARABINE IN ADULTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA

N. Short[1,*], H. Kantarjian[1], F. Ravandi[1], X. Huang[1], L. Xiao[1], G. Garcia-Manero[1], W. Plunkett[1], V. Gandhi[1], K. Sasaki[1], N. Pemmaraju[1], N. Daver[1], G. Borthakur[1], N. Jain[1], M. Konopleva[1], Z. Estrov[1], T. Kadia[1], W. Wierda[1], C. DiNardo[1], M. Brandt[1], S. O'Brien[2], J. Cortes[1], E. Jabbour[1]
[1]The University of Texas MD Anderson Cancer Center, Houston, [2]The University of California - Irvine, Orange, United States

Background: Fludarabine and clofarabine are purine nucleoside analogues with clinical activity in acute myeloid leukemia (AML).
Aims: We designed a randomized phase II trial to evaluate the efficacy and safety of idarubicin and cytarabine with either clofarabine (CIA) or fludarabine (FIA) in adults with newly diagnosed AML. The primary objective was to compare the EFS rates of the two regimens.
Methods: Adults with newly diagnosed AML deemed suitable for intensive chemotherapy were randomized using a Bayesian adaptive design to receive CIA or FIA. All patients (pts) received idarubicin 10 mg/m^2 IV on D1-3 and cytarabine 1 g/m^2 IV daily on D1-5. Clofarabine and fludarabine were given at doses of 15 mg/m^2 and 30 mg/m^2, respectively, IV daily on D1-5. Pts with *FLT3*-ITD mutations could receive concomitant sorafenib. Responding pts could receive up to 6 cycles of consolidation at attenuated doses. Outcomes were compared to a historical cohort of pts <60 years of age who received idarubicin and cytarabine (IA) without a nucleoside analogue.
Results: Between 8/2011 and 6/2016, 182 pts were enrolled (CIA, n=106; FIA, n=76; Table 1).

Table 1.

Baseline characteristics

Characteristic*	CIA (n=106)	FIA (n=76)
Age (years)	53 [20-66]	49 [18-66]
WBC (10^9/L)	3.7 [0.6-103.0]	4.9 [0.5-59.4]
Hemoglobin (g/dL)	9.5 [7.3-13.1]	9.1 [7.5-13.1]
Platelets (10^9/L)	37 [1-1069]	41 [5-399]
BM blasts (%)	52 [1-96]	54 [11-96]
Diagnosis		
AML	103 (97)	73 (96)
High-risk MDS	3 (3)	3 (4)
Cytogenetics		
Diploid	48 (45)	34 (45)
-5, -7 and/or complex	29 (27)	19 (25)
Others	29 (27)	23 (30)
s-AML/t-AML	13 (12)	12 (16)
FLT3-ITD mutation	22/103 (21)	15/76 (20)
ELN risk		
Favorable/intermediate-1	43/101 (43)	29/69 (42)
Intermediate-2/adverse	58/101 (57)	40/69 (58)

*Continuous variables are listed as median [range] and categorical variables as n (%)

CIA, clofarabine, idarubicin and cytarabine; FIA, fludarabine, idarubicin and cytarabine; WBC, white blood cell; BM, bone marrow; AML, acute myeloid leukemia; MDS, myelodysplastic syndrome; s-AML/t-AML, secondary- or therapy-related AML; ELN, European LeukemiaNet

The imbalance of the arms was due to the better performance of CIA during the initial period of the trial. Treatment arms were well-balanced after randomization. 12 pts (55%) in the CIA arm and 8 (53%) in the FIA arm received sorafenib. The composite CR/CRp rate was similar between the two arms (80% for CIA *vs* 82% for FIA; P=0.84). CR was achieved in 72% and 74% in the CIA and FIA arms, respectively. MRD negativity rates at remission by multiparameter flow cytometry were higher in the CIA arm (80% *vs* 65%; P=0.07). 37 pts (35%) in the CIA arm and 28 (38%) in the FIA arm underwent allogeneic stem cell transplant in first remission. The median duration of follow-up was 27 months (range, 1-58). Median EFS for pts who received CIA and FIA were 13 months and 12 months, respectively; the 2-year EFS rate was 44% in both arms (P=0.91). Median OS were 24 months and not reached, and the 2-year OS rates were 51% and 57%, respectively (P=0.23). No differences in EFS or OS were observed according to baseline factors, including cytogenetics, mutations or ELN risk group. CIA was generally associated with more adverse events compared to FIA, including a higher rate of transaminase elevation (29% *vs* 4%), hyperbilirubinemia (26% *vs* 9%), and rash (29% *vs* 12%). Early mortality was similar in the 2 arms (60-day mortality: 4% for CIA *vs* 1% for FIA; P=0.32). We compared outcomes of pts treated with either CIA/FIA to a historical cohort treated with IA (n=92). Pts in the CIA/FIA group with *FLT3* mutations who received sorafenib (n=20) were excluded from this analysis. The two cohorts were similar with respect to pretreatment characteristics analyzed, including age, cytogenetics, and ELN risk. No differences were observed in CR/CRp rates, EFS or OS between the two groups. However, among pts <50 years of age, the median EFS for pts who received FIA (n=36), CIA (n=28) and IA (n=34) was not reached, 10 months and 9 months, and the 2-year EFS rates were 58%, 33% and 30%, respectively (P=0.05 for FIA *vs* IA; P=0.79 for CIA *vs* IA). For these pts <50 years of age, the median OS was not reached, 22 months and 15 months, and the 2-year OS rates were 72%, 46% and 36%, respectively (P=0.009 for FIA *vs* IA; P=0.23 for CIA *vs* IA).
Summary/Conclusions: CIA and FIA have similar efficacy in younger pts with newly diagnosed AML, although FIA is associated with a better toxicity profile. FIA may improve outcomes compared to IA in pts <50 years of age.

P210

OVERALL SURVIVAL AND TRANSPLANTATION IN PATIENTS WITH FLT3 MUTATIONS: SUBGROUP ANALYSIS OF A PHASE 3 STUDY OF CPX-351 VERSUS 7+3 IN OLDER ADULTS WITH NEWLY DIAGNOSED, HIGH-RISK ACUTE MYELOID LEUKEMIA

B.C. Medeiros[1,*], D. Hogge[2], L.F. Newell[3], D.L. Bixby[4], S.R. Solomon[5], S.A. Strickland[6], T.L. Lin[7], H. Erba[8], B.L. Powell[9], N. Podoltsev[10], R. Ryan[11], M. Chiarella[11], A.C. Louie[11], J. E. Lancet[12]
[1]Stanford University School of Medicine, Stanford, CA, United States, [2]Gordon and Leslie Diamond Health Care Centre, Vancouver, British Columbia, Canada, [3]Oregon Health and Science Univ, Portland, OR, [4]University of Michigan, Ann Arbor, MI, [5]BMT Group of Georgia, Atlanta, GA, [6]Vanderbilt-Ingram Cancer Center, Nashville, TN, [7]University of Kansas Medical Center, Kansas City, KS, [8]University of Alabama at Birmingham, Birmingham, AL, [9]Wake Forest Baptist Comprehensive Cancer Center, Winston-Salem, NC, [10]Yale Univ. School of Medicine, New Haven, CT, [11]Jazz Pharmaceuticals, Palo Alto, CA, [12]H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, United States

Background: Approximately 20% to 30% of patients with acute myeloid leukemia (AML) have FLT3 mutations; these patients often experience rapid post-induction relapse, highlighting the need for therapies that provide an improved bridge to stem cell transplantation. CPX-351 is a liposomal formulation that delivers a synergistic 5:1 molar ratio of cytarabine and daunorubicin. CPX-351 demonstrated significantly prolonged overall survival (OS) *versus* cytarabine/daunorubicin (7+3) in a randomized, open-label, controlled phase 3 trial in patients aged 60 to 75 years with newly diagnosed, high-risk AML (Lancet, *et al.* ASCO 2016). A study of the *ex vivo* cytotoxicity of CPX-351 found that AML blasts with the FLT3-ITD phenotype were 5-fold more sensitive to CPX-351 than those with wild type FLT3 (Gordon, *et al.* Leuk Res. 2017;53:39-49).
Aims: The current analysis of the phase 3 trial therefore investigated outcomes in the subset of patients with FLT3 mutations.
Methods: Enrolled patients were randomized 1:1 to receive induction with 1 to 2 cycles of CPX-351 (100 units/m2 [cytarabine 100 mg/m2+daunorubicin 44 mg/m2] on Days 1, 3, and 5 [2nd induction: Days 1 and 3 only]) or 7+3 (cytarabine 100 mg/m2/day x 7 days [2nd induction: x 5 days]+daunorubicin 60 mg/m2 on Days 1, 2, and 3 [2nd induction: Days 1 and 2 only]). Patients who achieved complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 consolidation cycles.
Results: Of the 274 patients who were assessed for FLT3 mutations and received study treatment, 22/138 (16%) patients in the CPX-351 arm and 20/136 (15%) patients in the 7+3 arm had baseline FLT3 mutations. AML subtypes in FLT3+ patients were: therapy-related AML (19%); AML after myelodysplastic syndrome (MDS) with (38%) or without (10%) prior hypomethylating agents; AML after chronic myelomonocytic leukemia (12%); and de novo AML with MDS karyotype (21%). In FLT3+ patients, median OS was longer with CPX-351 (10.25 months) *versus* 7+3 (4.55 months; hazard ratio=0.57 [95% CI: 0.24, 1.33]; P=0.093; see Figure 1), and the rate of CR+CRi was higher (68% *vs* 25%). A greater number of FLT3+ patients treated with CPX-351 were able to undergo stem cell transplantation (n=10/22 [45%]; 4 patients were alive as of this analysis, after a median post-transplant follow up of 692 days [range: 96-769]) compared with 7+3 (n=2/20 [10%]; neither patient was still alive). The adverse event profile (reported during treatment or within 30 days of discontinuation) of CPX-351 in FLT3+ patients was comparable to that of 7+3 and consistent with the overall study population. Serious treatment-emergent adverse events (TEAEs) were experienced by 7 (32%) FLT3+ patients in the CPX-351 arm and 10 (50%) patients in the 7+3 arm; individual serious TEAEs in ≥2 patients included febrile neutropenia (n=2 in each arm), respiratory failure (n=1 in each arm), cardiac failure (n=2 with CPX-351), and cerebral hemorrhage (n=2 with 7+3).
Summary/Conclusions: CPX-351 demonstrated numerical improvement in median OS in older patients with newly diagnosed, FLT3+ high-risk AML and

allowed more patients to undergo stem cell transplantation. The safety of CPX-351 in this subpopulation was in line with that of previous studies and the overall phase 3 population. This analysis was limited by small number of patients.

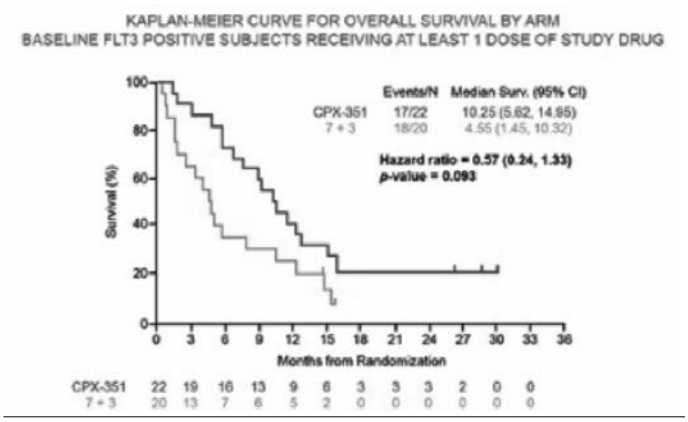

Figure 1.

P211

NIVOLUMAB MAINTENANCE THERAPY FOR PATIENTS WITH HIGH-RISK ACUTE MYELOID LEUKEMIA IN REMISSION

T. Kadia[1,*], H. Kantarjian[1], E. Jabbour[2], F. Ravandi[1], N. Daver[1], P. Cardenas[1], M. Brandt[1], M. Konopleva[1], J. Cortes[1]
[1]Leukemia, [2]MD Anderson Cancer Center, Houston, United States

Background: Dose intensification and newer drug combinations during induction have led to high rates of complete remission (CR) in pts with newly diagnosed AML. However, disease relapse remains a major source of failure. With the exception of allogeneic (allo) stem cell transplant (SCT), there are few options for post-consolidation maintenance of remission in high-risk pts. Prior attempts to develop maintenance therapy using cytotoxic drugs in AML have been unsuccessful. Immune mediated disease control by engaging tumor-specific cytotoxic T-cells may be important in suppressing leukemia relapse, as is seen with graft *vs* leukemia effect following allo SCT. Immune checkpoint inhibitors may be effective in restoring host immune surveillance in the setting of post-remission maintenance.
Aims: We designed a pilot phase II clinical trial studying the efficacy and safety of nivolumab (nivo) as maintenance therapy in AML pts with high-risk disease in remission, who were not being considered for SCT.
Methods: AML pts ≥18 years with a high-risk feature in 1st CR (CR1) or any patient in 2nd CR (CR2) who had received induction and at least 1 consolidation cycle were eligible for enrollment. Pts should be within 12 months of achieving CR, have PS ≤2, and adequate organ function. Pts were treated with nivo 3mg/kg IV every 2 weeks for 6 months. 1 cycle was 4 weeks. After 6 months, nivo could be given every 4 weeks until 12 months on study, and then every 3 months until relapse. All pts had baseline cytogenetic and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. Peripheral blood and bone marrow samples were collected at baseline and during treatment for immune correlative studies to explore immune cell repertoire and biomarkers for response.
Results: Eight pts have been treated, with a median age of 60 years (range, 49-71). 7 pts were in CR and 1 in CRi at the time of enrollment; 5 pts (63%) were in CR1, 2 pts (25%) were in CR2, and 1 pt (13%) in CR4 was inadvertently enrolled and treated on the trial. Baseline characteristics are outlined in Table 1. AML-related mutations detected at start of therapy include: IDH2 (n=2), NPM1 (2), TET2 (2), and 1 each of TP53, JAK2, ASXL1, and DNMT3a. High risk features at the time of enrollment were as follows: 2 (25%) persistent MRD, 2 (25%) adverse karyotype, 1 (13%) adverse mutational profile, and 3 pts (38%) in CR2 or beyond. Pts have received a median of 4 (1 – 13) cycles of therapy. With a median followup of 6+ months (1 – 14), the 6- and 12-month estimated RFS were 88% and 73%, respectively. The 6- and 12-month estimated OS were 100% (Figure 1). The one patient who died was discovered after enrollment to actually be in CR4. This patient relapsed approximately 8 months after achieving CR4. The regimen was well tolerated overall, with 4 pts having possible immune-related events. 1 patient had grade 3 thyroiditis leading to hypothyroidism, treated successfully with steroids and thyroid hormone supplementation, who continues on treatment. 1 patient had grade 4 transaminase elevation which responded to dose interruption and who continues on treatment. 2 pts had grade 3 possible pneumonitis treated successfully with steroids and dose interruption – both of whom continue on treatment (Table 1).
Summary/Conclusions: Nivo appears to be a feasible maintenance strategy in high-risk AML pts who are not candidates for SCT. The study continues to surpass the pre-specified expected rate of 6-month relapse-free survival of high-risk pts based on a historical cohort. Correlative studies profiling the immune repertoire of pts before and during treatment are being finalized and will be summarized.

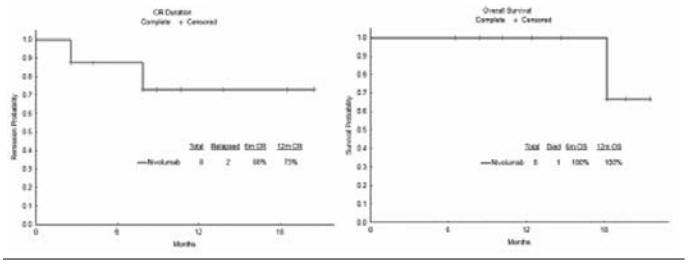

Figure 1.

Table 1.

Characteristic	Median (range)
Age	60 (49 - 71)
WBC [x10^9/L]	3.8 (1.3 - 8)
Platelets [x10^9/L]	125 (32 - 272)
LDH	465 (417 - 630)
Albumin	3.9 (3.4 - 4.6)
Bilirubin	0.5 (0.3 – 0.8)
Creatinine	0.7 (0.5 – 0.8)

HIGHER EXPRESSION OF LONG NON-CODING RNA KIAA0125 IS ASSOCIATED WITH CHARACTERISTIC CLINICAL AND BIOLOGICAL FEATURES AND IS AN INDEPENDENT POOR PROGNOSTIC FACTOR IN ACUTE MYELOID LEUKEMIA

S.-Y. Hung[1,*], C.-C. Lin[1,2,3], H.-A. Hou[1], W.-C. Chou[1,2], H.-F. Tien[1]
[1]Division of Hematology, Department of Internal Medicine, [2]Department of Laboratory medicine, National Taiwan University Hospital, [3]Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei City, Taiwan, Republic of China

Background: Long non-coding RNAs (lncRNAs) are non-protein coding RNAs longer than 200 nucleotides. Recently, a number of lncRNAs have been shown to play important roles in cancer biology. lncRNA *KIAA0125* is one of the 11 genes in an expression signature significantly associated with prognosis in cytogenetically normal acute myeloid leukemia (AML) patients as shown in our previous report. It is also among another set of 17 leukemia stem cell (LSC) genes, identified through xenotransplantation model in NSG mice, which predict inferior treatment response in AML.
Aims: *KIAA0125* gene is localized on chromosome 14q32.33; its functions remain unexplored. One study reported that it might be involved in neurogenesis including induction of astrocytosis, preventing formation of dopaminergic neurons. Another study showed that it could potentiate cell invasion and migration in gallbladder cancer. Its clinical significance in hematologic malignancies has not been explored yet. Since independent studies have reported *KIAA0125* as an important gene for unfavorable prognosis, in this study we aimed to investigate its clinical relevance in AML.
Methods: We performed global mRNA arrays for bone marrow samples from 347 newly diagnosed de novo AML patients in the National Taiwan University Hospital, who had adequate cryopreserved cells and detailed demographic, clinical, and genetic data for analysis. The *KIAA0125* expression level extracted from the array data was analyzed for its clinical relevance. We also validated our findings by analyzing the public databases of AML.
Results: The 347 patients were divided into two groups based on the median level of *KIAA0125* expression on the arrays. Higher *KIAA0125* expression was inversely associated with favorable karyotypes including t(8;21) and t(15;17). Patients with M1 by the French-American-British classification more frequently had higher *KIAA0125* expression (p <0.001), while those with M3 (acute promyelocytic leukemia) had significantly lower levels of *KIAA0125* expression (p <0.001). To investigate the association of gene mutations with *KIAA0125* expression in AML, we analyzed mutations of 17 AML-associated genes. We found that patients with higher *KIAA0125* expression had significantly higher incidence of *FLT3*-ITD (28.7% *vs* 19.7%, p=0.048), and mutations of *RUNX1* (18.4% *vs* 10.4%, p=0.034), and *DNMT3A* (24.1% *vs* 13.9%, p=0.015), compared to those with lower *KIAA0125* expression. Among the 227 patients who received standard chemotherapy, those with higher *KIAA0125* expression had a lower complete remission rate (61.2% *vs* 84.7%, p <0.001), and shorter overall survival (median OS, 23.7 months *vs* 116.8 months, p = 0.001) than those with lower *KIAA0125* expression after a median follow-up of 57.0 months. The prognostic significance could be validated in another two independent cohorts, TCGA and GSE12417. In multivariate analyses, higher expression of *KIAA0125* remained to be an unfavorable prognostic factor for OS independent of age, white blood cell counts, karyotype, *FLT3*-ITD, *CEBPA* double mutations,

RUNX1 mutation, *MLL*-PTD, *WT1* mutation, and *TP53* mutation (p=0.011).
Summary/Conclusions: Higher expression of *KIAA0125* in AML patients was correlated with mutations of *RUNX1, DNMT3A*, and *FLT3*-ITD but negatively associated with favorable karyotypes such as t(8;21) and t(15;17). Higher expression of *KIAA0125* appeared to be an independent unfavorable prognostic factor in our cohort, and its negative prognostic impact could be validated in another two large independent cohorts of AML. The close association of *KIAA0125* expression with LSC signatures might in part explain its unfavorable impact on the survival of AML patients.

P213

LEUKEMIC STEM CELLS CAN BE DETECTED IN A CONSIDERABLE PERCENTAGE OF PATIENTS WITH ACUTE MYELOID LEUKEMIA AT DIAGNOSIS AND IS A SIGNIFICANT PROGNOSTIC FACTOR

O. Pérez-López[1,*], T. Caballero-Velázquez[1], I. Álvarez-Laderas[1], P. Hernández-Díaz[1], A. M. Márquez-Matito[1], J. González-Campos[1], R. Morales-Camacho[1], C. Prats-Martín[1], M.T. Vargas-de los Monteros[1], R. Bernal-Ruíz[1], J.A. Pérez-Simón[1]
[1]Virgen del Rocío University Hospital, Sevilla, Spain

Background: There is a growing interest on the identification of leukemic stem cells (SC) as a potential prognostic factor in patients with acute myeloid leukemia (AML). Several studies identify these cells as CD34+CD38-Lin-, although there is a controversy about its phenotypic identification and prognostic value.
Aims: To identify SC in a cohort of patients with AML and evaluate their prognostic value in a series of newly diagnosed AML patients.
Methods: The presence of SC (CD34+CD38-Lin-) in bone marrow samples was prospectively evaluated in a consecutive series of 67 newly diagnosed AML patients by flow cytometry, between may'13-oct'16. All patients receive intensive chemotherapy according to PETHEMA protocol. We evaluated response, relapse rate and overall (OS) and event free survival (EFS).
Results: Out of the 67 patients [34 men/33 women, median age 54 (0-78)], 58 (86.6%) have SC at diagnosis. 37.9% of them (n=22) achieved complete remission (CR) with a negative minimal residual disease (MRD) *vs* 77.8% (7/9) among patients without SC (p=0.03). Among patients who obtained CR with a negative MRD (n=29), no one suffer a leukemic relapse in the non SC *vs* 5/22 (22.7%) in the SC group (p=0.2). Considering the intermediate risk group according to cytogenetic / molecular features, 100% of patients without SC at diagnosis achieve a negative MRD (5/5) *vs* 14/41 (34.1%) among those in the SC group (p=0.008). OS at 9 months was 89 *vs* 56% (p=0.043), and the EFS 78 *vs* 48% (p=0.054) in the non SC and SC group, respectively (Figure 1).

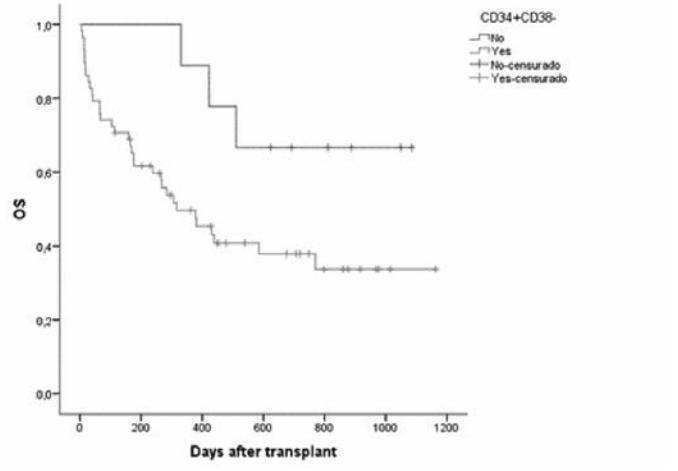

Figure 1.

Summary/Conclusions: SC can be detected in a considerable group of patients with AML at diagnosis. The presence of SC is a prognostic factor in terms of response, OS and EFS. Accordingly, SC detection could help to identify prognosis subgroups of patients with different prognostic among those in the intermediate risk group by genetics/molecular assays.

POST-REMISSIONAL AND PRE-TRANSPLANT ROLE OF MINIMAL RESIDUAL DISEASE DETECTED BY WT1 IN ACUTE MYELOID LEUKEMIA: A RETROSPECTIVE COHORT STUDY

C. Frairia[1,*], S. Aydin[1], E. Audisio[1], L. Riera[2], S. Aliberti[2], B. Allione[1], A. Busca[3], S. D'Ardia[1], C.M. Dellacasa[3], A. Demurtas[2], A. Evangelista[4], G. Ciccone[4], P. Francia di Celle[2], B. Nicolino[1], A. Stacchini[2], F. Marmont[1], U. Vitolo[1]
[1]Department of Hematology, [2]Department of Pathology, [3]Bone Marrow Transplant Center, University-Hospital Città della Salute e della Scienza, Torino, Italy, [4]Unit of Clinical Epidemiology, University-Hospital Città della Salute e della Scienza and CPO Piemonte, Torino, Italy

Background: In acute myeloid leukemia (AML) the detection of residual leukemic cells at a submicroscopic level (minimal residual disease - MRD) is still under investigation. In about 30-40% of AML lacking a specific molecular target, quantitative real-time polymerase chain reaction (QRT-PCR) has been used to detect transcripts commonly overexpressed in AML. Among a large number of candidates, Wilms tumor gene 1 (*WT1*) has been proposed as a promising MRD marker.
After the standardization of QRT-PCR on behalf of the European LeukemiaNet (ELN), subsequent studies investigated the role of *WT1* expression in AML with controversial results.
Aims: To assess the role of *WT1* expression as a MRD marker after intensive induction chemotherapy and before allogeneic hematopoietic cell transplantation HCT (allo-HCT) in a large cohort of AML patients treated in a single institution.
Methods: The present retrospective cohort study included adult patients with untreated AML consecutively diagnosed between 2004 and 2014 in the Hematology Unit of the University-Hospital Città della Salute e della Scienza of Torino, Italy. The study was approved by the Ethical Committee and was registered at www.clinicaltrials.gov as NCT02714790. Among 255 enrolled patients, MRD was investigated in those in first complete remission (CR) with an available at diagnosis and at two further time-points: after induction (n=117) and prior allo-HCT (n=65). Patients with baseline *WT1* <250 copies were excluded. All patients underwent intensive induction chemotherapy with curative intent and subsequent consolidation chemotherapy according to the AML risk assessment (autologous peripheral stem cell transplantation for low risk and allo-HCT for intermediate and high risk patients). Effect of post induction *WT1* expression on disease-free survival (DFS) and overall survival (OS) and of pre allo-HCT *WT1* on the cumulative incidence of relapse (CIR) were investigated.
Results: Baseline BM *WT1* expression were not found significantly associated with demographic, clinical and disease biological features at diagnosis. Baseline BM *WT1* expression lacked even to show an association with response to induction chemotherapy (OR 1.16; 95% CI 0.90-1.50, p=0.244).
Median OS and DFS were significantly shorter in patients in first CR with >350 *WT1* copies after induction compared to those with ≤350 (OS 17 *vs* 95 months with HR 2.13; 95% CI 1.14-3.97, p=0.018 and 3-year DFS rates 15% *vs* 55% with a HR of 2.81; 95% CI 1.14-6.93, p=0.025).
Adding the BM *WT1* in the model along with other factors determines an increase of the C-statistic from 0.6996 to 0.7193 for OS (NRI=0.384) and from 0.7413 to 0.7920 (NRI=0.4037) for DFS. Before allo-HCT, patients with *WT1* >150 copies (n=18) had a significantly higher CIR compared to those with *WT1* ≤150 (n=47), HR 4.61; 95% CI 1.72-12.31, p=0.002.
Summary/Conclusions: The results of the present study showed that BM *WT1* is associated with survival in patients in CR in two decisive time-point for treatment planning: after induction treatment and before allo-HCT. The prognostic role of *WT1* resulted independent from other well-established risk factors. Therefore, *WT1* may represent an additional MRD tool for risk stratification in patients nowadays classified in CR, especially in the high risk MRD positive subgroup in which a risk-adapted approach may have a role. Published evidences available so far supported these suggestions, but mainly due to methodological issues, the role of *WT1* is still a matter of debate. Prospective randomized studies are required to confirm these results.

P215

DIFFERENTIATION SYNDROME ASSOCIATED WITH ENASIDENIB (AG-221), A SELECTIVE INHIBITOR OF MUTANT ISOCITRATE DEHYDROGENASE 2 (MIDH2)

A.T. Fathi[1,2,*], C.D. DiNardo[3], I. Kline[4], L. Kenvin[4], I. Gupta[4], E.C. Attar[5], E.M. Stein[67], S. de Botton[8]
[1]Massachusetts General Hospital Cancer Center, [2]Harvard Medical School, Boston, [3]The University of Texas MD Anderson Cancer Center, Houston, [4]Celgene Corporation, Summit, [5]Agios Pharmaceuticals, Inc, Cambridge, [6]Memorial Sloan Kettering Cancer Center, [7]Weill Cornell Medical College, New York, United States, [8]Institut Gustave Roussy, Villejuif, France

Background: Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of mIDH2 enzymes. Preclinical studies showed that exposing myeloblasts from patients (pts) with acute myeloid leukemia (AML) to enasidenib *ex vivo* resulted in differentiation of leukemic marrow blasts into mature, fully functional neutrophils (Yen *et al.*, *Cancer Discov*, 2017). Enasidenib can result in IDH-inhibitor-associated differentiation syndrome (IDH-DS) in treated pts, with manifestations akin to retinoic acid syndrome seen during therapy of acute promyelocytic leukemia.
Aims: To characterize the prevalence, characteristics, and course of IDH-DS in pts with relapsed or refractory (R/R) AML receiving enasidenib 100 mg daily in a phase 1 dose-escalation and expansion study (NCT01915498). This dose is currently under study in a multicenter, randomized, phase 3 trial comparing enasidenib with conventional care regimens in R/R AML pts (NCT02577406).

Methods: An independent Differentiation Syndrome Review Committee (DSRC) was formed to review potential cases of IDH-DS. The DSRC identified and agreed upon a series of signs and symptoms possibly characteristic of IDH-DS, including fever, lung infiltrates, pleural or pericardial effusions, rapid weight gain, edema, and azotemia. In all, 27 cases (8 of investigator-reported IDH-DS and 19 with characteristics suggestive of IDH-DS) were identified and retrospectively reviewed by the DSRC to determine their consistency with IDH-DS.
Results: The DSRC determined 13 cases (11.9% of 109 R/R AML pts in the enasidenib 100 mg/day dosing cohort) to be consistent with IDH-DS. Median time to onset was 30 days (range 7-116). Manifestations of IDH-DS in >2 pts were dyspnea (n=10), pyrexia (9), lung infiltrates (8), pleural effusion (5), and kidney injury (3). IDH-DS was effectively managed with systemic corticosteroids in 12/13 cases. Leukocytosis accompanied 4/13 cases, for which hydroxyurea was employed for cytoreduction. Enasidenib was interrupted for 9 pts (for a median of 7 days), but dose reductions or enasidenib discontinuation were not required for pts with IDH-DS. Six of the 13 pts had clinical responses (2 complete remissions [CR], 2 CRs with incomplete hematologic recovery, 1 partial remission, and 1 morphologic leukemia-free state), 6 pts had stable disease, and 1 pt had progressive disease.
Summary/Conclusions: Systemic corticosteroids, close hemodynamic management, and hydroxyurea (in the presence of leukocytosis) are effective IDH-DS management strategies; they should be administered promptly when IDH-DS is suspected, and continued until improvement. Enasidenib interruption can be considered if initial intervention is unsuccessful. IDH-DS represents a novel clinical finding in pts with m*IDH2* AML treated with enasidenib, and is likely due to its suggested mechanism of action, myeloblast differentiation.

Aggressive Non-Hodgkin lymphoma - 1st line

Background: Intravascular large B-cell lymphoma (IVLBCL) is a rare type of extranodal large B-cell lymphoma characterized by the selective growth of lymphoma cells within the lumina of vessels, classically reported with poor responses to chemotherapy. Due to its low incidence and rarety of tumor cells, diagnosis of IVLBCL remains difficult and many issues remain unresolved, regarding both clinical features and therapeutic strategies.
Aims: Our work aims to describe clinical presentation and outcome of IVLBCL patients treated in French LYSA centers between 2000 and 2016.
Methods: All LYSA centers were asked to report and update clinical data about IVLBCL patients treated. No central pathology review was performed for the present study, but all cases were classified by LYSA pathologists. Local investigators reported disease characteristics and updated patients' outcome (clinical examination, standard biological parameters, bone marrow biopsy, CT scan at baseline, CT response evaluation and outcome).
Results: We identify 65 IVLBCL patients treated in 23 LYSA centers during the studied period. Median age was 67.8 years (range 22-91). In note, two third of patients presented with IPI score >3 (67%) and all patients had a stage IV disease. As expected in Western patients, cutaneous and CNS involvement were highly frequent, respectively 33% and 39%. But interestingly, hemophagocytic syndrome were observed in nearly half of the patients (41%), while it was mainly described in Asian series. Despite classically delayed diagnosis in IVLBCL, only 2 cases were confirmed post-mortem and almost all alive patients at diagnosis (n=58) were treated with rituximab-containing chemotherapy regimen (92%). Regarding first line treatment, 83% of patients were treated with anthracycline-based regimens, with CNS prophylaxis for half of them (47%), and seven patients underwent autologous stem cell transplantation upfront. The median progression free survival was 29.4 months and median overall survival was 63.8 months (Figure 1). Pathological features (including cell of origin characterization, C-MYC expression, adhesion protein expression level) investigation is ongoing and will be presented at the time of the meeting.

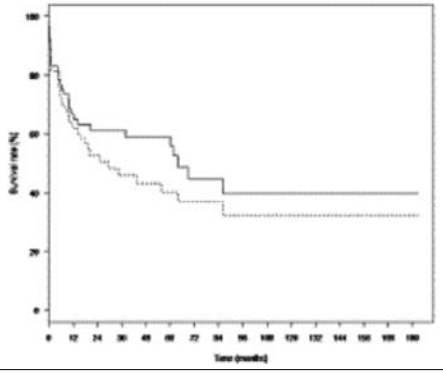

Figure 1.

Summary/Conclusions: The present study is the largest European IVLBCL series. It shows that despite the use of modern immune-chemotherapy, IVLBCL remains an aggressive lymphoma entity. In particular, these patients are highly exposed to early relapse and therefore should be considered for innovative frontline therapies.

P218

OUTCOME OF ELDERLY DLBCL PATIENTS (≥80 YEARS) TREATED WITH ANTHRACYCLINE BASED CHEMOTHERAPY; R-CHOP DOSE REDUCTION IS NOT NECESSARY FOR EVERYBODY

M. Trněný[1,*], A. Janikova[2], A. Sykorova[3], V. Prochazka[4], H. Mocikova[5], P. Klener[1], D. Salek[2], D. Belada[3], K. Benesova[1], R. Pytlik[1], P. Blahovcova[6], L. Boudova[7], V. Campr[8]
[1]Charles University General Hospital, Prague, [2]University Hospital, Brno, [3]University Hospital, Hradec Kralove, [4]University Hospital, Olomouc, [5]University Hospital Kralovske Vinohrady, [6]CLSG Data Center, Prague, [7]University Hospital, Pilsen, [8]University Hospital Motol, Prague, Czech Republic

Background: Management of elderly patients (above ≥80y) is difficult and only limited number of patients could be treated by curative approach with anthracycline based chemotherapy. Dose reduction of particular drugs is used very often and it varies based on pt's characteristics and center preferences. There is however lack of randomized or at least non-randomized historical comparisons.
Aims: The objective of this study is to analyze elderly DLBCL patients prospectively registered in NiHiL Lymphoma Project and treated anthracycline based regimen in real world outside of clinical trials.
Methods: Patients (pts.) with informed consent are prospectively followed in multicenter Lymphoma Project since 1999. Diagnostic, therapeutic and follow up data are prospectively collected. There were 399 DLBCL pts older than 80year diagnosed in period 1999-2014 identified. Among 372 pts. with pathology review and essential data there were 112 pts. (30.1%) treated with R-CHOPlike chemotherapy. Analysis of clinical prognostic factors, therapy and toxicity was performed. Pearson, Kaplan-Maier and log rank tests were used.
Results: Median age was 81 years (80-88), 51.8% of men. Proportion of pts ³85 was 14.3%, with PS ≥2 (ECOG) 34.0%, with higher LDH 64.3%, with high or intermediate high IPI 49.1%, with bulky disease (≥10 cm) 17.0%, with lower albumin 27.7%, with Charlson Comorbidity Score (CCS) ≥4 25%. According to treatment choice of physician (intent to treat), pts. could be divided into 3 groups R-CHOP (CH) (cyclophosphamide –CF 750 mg/m^2, adriamycin – A - 50 mg/m^2) or R-MiniCHOP (miniCH) (CF 400 mg/ m^2, A 25 mg/ m^2, Peyrade 2011) or modified R-CHOP (modiCH) (CF 750 mg/m^{2}and A 25 mg/m^{2}or any other dose between CHOP and miniCHOP). There were 21 pts (18.8%) treated with CH, 38 (33.9%) with miniCH and 53 (47.3%) with modiCH. There were no signficant differences between the subgroups, except higher proportion of bulk in modiCH *vs* miniCH and CH (35% *vs* 12.9% *vs* 7.7% resp.; p 0.04) and cardiac comorbidity (60.5% *vs* 33.3% *vs* 30.2% resp.; p 0.02). Six and more cycles were administered in 71.4%, 63.1% and 58.5% pts. in CH, miniCH and modiCH resp. Following proportion of pts. received >80% (>50%) of original CHOP dose. For cyclophosphamide it was 66.7% (81%), 0% (50%) and 62.2% (79.2%) resp. and for A it was 57.1% (76.1%), 2.6% (15.8%) and 13.2% (49%) resp. for CH, miniCH and modiCH resp. There were observed 11 treatment related deaths (6 cardiac toxicity and 4 infection), 5 in miniCH and 6 in modiCH groups. The overall response rate was 76.8% with 59.8% CR/CRu. Median PFS and OS were 2.8y and 3.5y resp. (Figure 1A) with median follow up of 3.3y. There were found high beta2microglobulin (HR 2.2, p 0.05), low albumin (HR 1.9, p 0.05) and PS (p 0.05) as the only factors correlated with OS as well as PFS (data not shown). Pts who achieved CR or PR have significantly better OS median (as well as PFS) compared to stable or progressive disease with 4.6 *vs* 3.5 *vs* 0.8 *vs* 0.5 y. There was numerically (not significantly) better OS median for R-CHOP (4.6y) *vs* R-miniCHOP (3.2y) and R-modiCHOP (2.9y) (Figure 1B).

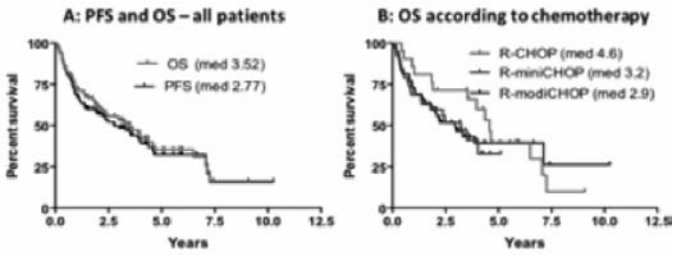

Figure 1.

Summary/Conclusions: Only one third of elderly DLBCL pts (≥80y) is treated with anthracycline based regimen. Performance status, albumin and beta2microblobulin levels were significantly associated with prognosis. In minority of these pts full dose of R-CHOP could be safely used and there is trend to better overall survival.
Supported by AZV 16-31092A.

P219

IMPROVED SURVIVAL IN PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA UP TO AGE 70 ONLY: A POPULATION-BASED STUDY ON INCIDENCE, PRIMARY TREATMENT AND SURVIVAL IN THE NETHERLANDS, 1989-2015

A. Dinmohamed[1,2,3,*], M. van der Meulen[4], O. Visser[5], J. Doorduijn[3], J. Bromberg[4]
[1]Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [2]Public Health, Erasmus Univeristy Medical Center, [3]Hematology, [4]Neuro-oncology, Erasmus MC Cancer Institute, Rotterdam, [5]Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, Netherlands

Background: PCNSL is a rare, aggressive form of an extranodal non-Hodgkin lymphoma that exclusively affects the CNS. Recent findings from the few available prospective studies demonstrated improved outcome in PCNSL. However, the results from such studies are inherent to patient selection. Population-based studies that assess long-term patterns of incidence, treatment and survival in PCNSL are virtually lacking.
Aims: The aim of this comprehensive nationwide population-based study was to assess trends in incidence, primary treatment and survival among adult PCNSL patients (pts) diagnosed during a 27-year period in the Netherlands.
Methods: We selected all adult (≥18 years) pts diagnosed with PCNSL of the diffuse large B-cell type in the Netherlands between 1989-2015 from the nationwide Netherlands Cancer Registry with survival follow-up through February, 2016. Pts diagnosed without pathological or cytological confirmation (n=50) and pts diagnosed at autopsy were excluded (n=32). Age-standardized incidence rates (ASR) were calculated per 1,000,000 person-years and standardized according to the European standard population. Data on primary treatment (*i.e.* no therapy, chemotherapy (CT) alone, radiotherapy (RT) alone, and CT+RT) were available for individual pts. Pts were categorized into 4 periods (1989-1994, 1995-2000, 2001-2007 and 2008-2014) and 3 age groups (18-60, 61-70 and >70 years). We calculated relative survival (RS) and the relative excess risk of mortality as measures of disease-specific survival.
Results: We included a total of 1,673 newly diagnosed PCNSL pts in the study (median age, 65 years; age range, 19-89 years; 53% males). The ASR of PCNSL increased from 3.0 in the first period (1989-1995) to 4.4 in the last period (2009-2015), which was consistently higher among males than in females throughout the entire study (4.8 *v* 4.0 in the last period). The age-specific incidence rates were 2.3, 9.0 and 10.0 in the first period for the three age groups (18-60, 61-70 and >70 years), as compared with 2.7, 18.7 and 19.5 in the last period. The application of CT+RT increased exclusively among pts age 18-60. More specifically, the proportions for the three age groups were 26, 18 and 4% in the first period, as compared with 60, 10 and 4% in the last period. The use of RT alone among pts age >60 decreased with each period, following the wider use of CT alone over time, especially for pts age 61-70 years. The proportions of CT alone for the three age groups were 11, 8 and 2% in the first period, as compared with 31, 64 and 32% in the last period. Of note, 38 and 26% of pts age >70 received no therapy and RT alone in the last period, respectively. Five-year RS only improved for pts age 18-70 (Figure 1). Five-year RS (95% confidence intervals) was 22% (16%>30%), 13% (7%>22%), and 3% (1%>10%) in the first period for the three age groups, as compared with 56% (47%>64%), 35% (28%>43%) and 6% (2%>13%) in the last period. A multivariable survival model confirmed the adverse effect of older age on excess mortality and an improvement of survival over time. However, when information on treatment was added to that model, the effect of period lost statistical significance. This suggest that treatment contributed to the improved survival over time. Older age remained a predictor of poor prognosis.

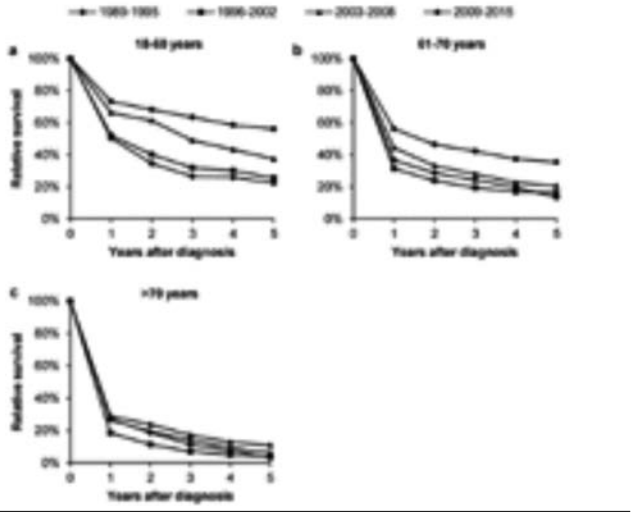

Figure 1.

Summary/Conclusions: The incidence of PCNSL steadily increases among

pts >60 years, which might in part be related to improved diagnostic practices among the elderly over time. RS increased over the past decades for pts age 70 or below. This is largely explained by the increased use of intensive therapy over time. Although the use of CT alone gradually increased among pts >70 years, their survival is still poor. Therefore, there is an urgent need to design specific trials for elderly PCNSL pts to improve their survival.

P220

CLINICAL CHARACTERISTICS AND LONG-TERM RESULTS OF TREATMENT OF DIFFUSE LARGE HEPATITIS C - ASSOCIATED NON-HODGKIN LYMPHOMA (DLBCL+C)

S. Lepkov[1,*], I. Subortseva[2], G. Tumyan[3], P. Zejnalova[3], O. Kolomejtsev[3], Y. Ryabukhina [3], A. Semenova[3], N. Kokosadze[3], N. Kupryshina[3], I. Komarov[3], O. Malikhova[3], S. [1]Russian National Research Medical University named after N.I. Pirogov, [2]National Research Center for Haematology, [3]National Research Center for Oncology named after N.N. Blochin, [4]City Clinical Hospital named after C.P. Botkin, [5]City Clinical Hospital named after V.M. Buyanov, [6]City Clinical Hospital named after V.M. Buyanov, Moscow, Russian Federation

Background: In the WHO classification (2008), hepatitis C virus distinguish as one of the etiological factors of multistage etiopathogenesis DLBCL.
Aims: The purpose of this study was evaluation of clinical features and results of treatment of diffuse krepnokletochnoy lymphoma associated with hepatitis C in comparison with a control group of patients with diffuse large lymphoma without viral hepatitis markers.
Methods: It was included 521 patients with DLBCL: 98 patients with DLBCL and markers of hepatitis C (DLBCL+C) and a control group of 422 patients with DLBCL without markers of hepatitis C (DLBCL-C).
Results: Patient's age ranged from 21 to 76 years (median was 47 years) in DLBCL+C; ranged from 23 to 81 years (median 61) in DLBCL -C (p=0.02). The male: female ratio was 1: 1.3 in patients with DLBCL +C; 1: 1.7 in the group DLBCL – C. Stage I and II were in 11% patients with DLBCL+C, and 48% patients with DLBCL - C; III and stage IV were detected in 89% patients with DLBCL+C and 52% of DLBCL-C (p=0.00002). Extranodal lesions detected in 72% in DLBCL+ C and in 26% in C DLBCL-C (p=0.006). In comparable groups localization of extranodal lesions was: spleen (52% to 23%), bone marrow involvement (43% and 27%), liver (18% and 1%). GCB / non-GCB histological variants ratio was 55% / 45% in DLBCL+C; 36% / 64% in DLBCL -C ratio GCB / (p=0.001). Hepatitis C virus RNA in blood was detected by PCR. Viral RNA was found in 78% (74 patients). High viral load was in 21% of patients. In 22% of cases markers of hepatitis C virus in blood were identified by ELISA. All patients received chemotherapy according to the scheme CHOP / R-CHOP. The frequency of complete remission was 60% in the group of patients with DLBCL+C and 63% of DLBCL-C. Median overall survival (OS) was 46 months in group DLBCL +C and 71 months in DLBCL -C (p=0.0003). Median progression-free survival (PFS) was 28 months in DLBCL+C 47 months in the control group (p=0.0002). According to the immunohistochemical variant of DLBCL: GCB DLBCL: median OS of 45 months in GCB DLBCL+C and 62 months in GCB DLBCL - C (p=0.002). Median PFS was 36 and 47 months in comparable group. Median OS was 18 months in non-GCB DLBCL+C and 70 months in non-GCB DLBCL-C (p=0.00001). Median PFS groups was 13 and 42 months, respectively. 58 patients received antiviral therapy after chemotherapy. Median OS was 63 months in GCB DLBCL+C with antiviral therapy and 28 months in GCB DLBCL+C without antiviral therapy (p=0.00002). Median PFS was 46 and 20 months, respectively. Median OS was 22 months in non-GCB DLBCL+C with antiviral therapy and 17 months in non-GCB DLBCL+C without antiviral therapy. Median PFS in the group was 11 and 15 months, respectively.
Summary/Conclusions: DLBCL+C characterized by aggressive course of the disease (younger age at onset of the disease, advanced stages, extranodal involvement), which is one more evidence possibility of separating DLBCL+C in a separate group. Although there is no difference in the effectiveness of the therapy. But disease-free survival in DLBCL patients+C was significantly worse.

P221

MAGNETIC RESONANCE IMAGING FOR EARLY DETECTION OF ANTHRACYCLINE CARDIOTOXICITY IN MALIGNANT LYMPHOMA

A.H. Laursen[1,*], J.J. Thune[2], M.B. Elming[3], P. Hasbak[4], R.S. Ripa[4], M. Hutchings[1]
[1]Department of Haematology, Rigshospitalet, [2]Department of Cardiology , Bipebjerg and Frederiksberg Hospital, [3]Department of Cardiology, [4]Department of Clinical Physiology, Nuclear Medicine and PET, Rigshospitalet, Copenhagen, Denmark

Background: Doxorubicin is a cornerstone of curative lymphoma treatment. However, doxorubicin therapy is limited by cardiac side effects including high-mortality heart failure (HF). Signs of cardiotoxicity often appear too late to avoid irreversible myocardial damage.
Aims: The aim of our study is to investigate the value of rubidium 82 positron emission tomography (82Rb PET), iodine 123 metaiodobenzylguanidine (123I MIBG) and cardiac magnetic resonance (MR) imaging in early detection of doxorubicin-induced cardiomyopathy and prediction of HF in patients with malignant lymphoma. We aim to identify early signs of cardiotoxic injury that predict the formation of interstitial fibrosis and subsequent HF. Here we present our preliminary MR data. 82Rb PET and 123I MIBG data will be analysed later.
Methods: The study is a prospective, clinical, single-centre study. The study aims to include 70 consecutive chemotherapy-naive lymphoma patients scheduled for intended curative chemotherapy without planned mediastinal radiation therapy. All patients undergo routine clinical examinations, but with supplementary imaging, including 1) baseline 82Rb PET and MR (prior to treatment); 2) acute 82Rb PET and MR (within 1 week of the first treatment); 3) subacute 123I-MIBG (after 2-3 months of therapy) and 4) late MR (1 year after the start of treatment). 82Rb PET imaging is performed at rest and during pharmacological stress testing with adenosine. It is primarily used to evaluate the acute effects of doxorubicin on myocardial perfusion. 123I MIBG is used for detection of doxorubicin-induced subacute changes in the myocardial adrenergic neurons. Cardiac MR is performed with late gadolinium enhancement and provides information on acute and late changes in left and right ventricular function, atrial and ventricular volumes, myocardial mass and interstitial fibrosis. Statistical analyses were done in R (version 3.2.0) as paired difference tests using Wilcoxon signed rank test. P-values <0.05 were considered significant.
Results: As of March 1st 2017, 61 patients have been included. In 33 cases, the time of intended follow-up has been reached. Four patients died prior to follow-up, including one patient who died before the acute imaging procedures. Four patients were excluded due to compliance problems. One patient was excluded due to disease downstaging resulting in omittance of doxorubicin from the treatment plan. Of the 24 patients with complete data from both the baseline and late MR scans, 16 had lower LVEF values at follow-up: 0-5% (n=3), 6-10% (n=8), 10-15% (n=4) and >20% (n=1). Mean LVEF at follow-up was significantly lower (57.1%) compared to baseline LVEF (62.0%; p=0.01) and acute LVEF (64.3%; p=0.002). The LVEF decline from baseline to follow-up was paralleled by an increase in mean left ventricular end diastolic volume (LVEDV) of 10.0mL (p=0.03). Interestingly, an increase in LVEDV was already registered at the acute MR scan (7.3mL; p=0.03). The increase in LVEDV from the acute MR to follow-up was not significant. We also registered an acute increase of 7.4mL in mean stroke volume (SV) (p=0.02). However, from the acute MR to follow-up MR we found a significant decline in SV (p=0.02). There was no difference in SV from baseline to follow-up (p=0.7). The acute changes in LVEDV did not predict LVEF declines from baseline to follow-up (Figure 1).

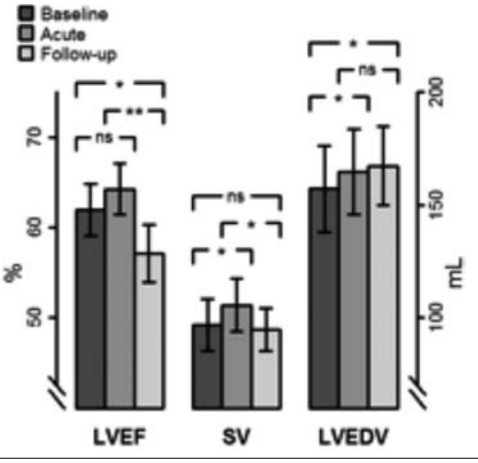

Figure 1.

Summary/Conclusions: Our preliminary show that cardiac MR can be used for detection of declining LV function 1 year after after doxorubicin exposure. It appears that cardiac MR may also provide information on acute functional changes in LVEDV and SV. We hope that our 82 Rb PET and 123I MIBG data will provide additional early signs of doxorubicin cardiotoxicity that can be used to predict subsequent development of HF.

RELAPSE CHARACTERISTICS AND THE ROLE OF SURVEILLANCE COMPUTED TOMOGRAPHY IN AGGRESSIVE NON-HODGKIN LYMPHOMA

K.-W. Kang[1,*], Y. Park[1], D.S. Kim[1], E.S. Yu[1], J.H. Kim[1], S.R. Lee[1], H.J. Sung[1], S.J. Kim[2], C.W. Choi[1], B.S. Kim[1]
[1]Department of Internal Medicine, Korea University School of Medicine,

[2]Department of Internal Medicine, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of

Background: The use of surveillance computed tomography (CT) is usual practice for cases of complete remission (CR) in aggressive non-Hodgkin lymphoma (aNHL). However, there is a lack of evidence to support this strategy.
Aims: To determine whether surveillance CT could contribute to the improvement of survival in relapsed aNHL patients, we retrospectively analyzed our institutional lymphoma registry, which enrolled consecutive patients with lymphoma from June 1995 to October 2016. Of 1,385 aNHL patients in the registry, 664 patients achieved CR and received follow-up through clinical visits, with or without surveillance CT.
Methods: Patients who met the following inclusion criteria were selected: i) histologic diagnosis of aNHL (diffuse large B-cell lymphoma, Burkitt lymphoma, and B-cell lymphoblastic lymphoma, peripheral T-cell lymphoma not otherwise specified, angioimmunoblastic T-cell lymphoma, anaplastic large cell lymphoma, NK/T-cell lymphoma, and T-cell lymphoblastic lymphoma); ii) patients who achieved CR after frontline or salvage chemotherapy with curative intent; and iii) time from the date of diagnosis to the date of last follow-up longer than 12 months. All patients in CR after frontline therapy were followed-up with clinical visits (symptom assessment, physical examination, and blood tests) every 1 to 6 months. Surveillance CT covering the neck, chest, or abdomen were performed every 3 or 6 months or when clinically indicated in the first 2 years, and then every 6 or 12 months or when clinically indicated thereafter. The decisions regarding the surveillance strategy (clinical visit with appropriate blood chemistry with or without regular surveillance CT) were at the discretion of the treating physicians.
Results: Relapse was detected in 171 patients, of whom 152 had undergone surveillance CT during follow-up. Of these 152 patients, asymptomatic relapse was detected in 67 (44%) by surveillance CT and symptomatic relapse outside the surveillance interval was detected in the other 85 (56%). Detection of asymptomatic relapse by surveillance CT did not improve either the overall or post-relapse survival in the relapsed aNHL patients. In addition, the interval of surveillance CT (3 or 6 months) did not affect survival. No subgroups were identified that favored the use of surveillance CT to detect relapse. Additionally, we analyzed the impact of surveillance CT in patients with refractory or relapsed aNHL who achieved CR after salvage chemotherapy (CR2). Of 315 aNHL patients relapsed/refractory to frontline chemotherapy (144 refractory and 171 relapsed patients), 99 patients achieved CR after salvage chemotherapy (18 refractory and 81 relapsed patients) and these patients were followed with clinical visits, with or without surveillance CT. Relapse was detected in 42 patients (42/99; 42.4%). A total of 27 (64.3%) and 15 patients (35.7%) were identified as relapsed by methods other than CT scan and using surveillance CT, respectively. There was no significant difference in the median PRS between the two groups (12.5 months, 95% CI: 2.8 to 22.1 months *vs* 10.7 months, 95% CI: 0 to 41.5 months; p=0.182] (Table 1).
Summary/Conclusions: In conclusion, this study suggests that routine surveillance CT in aNHL patients for the detection of asymptomatic relapse might have a limited role in improving survival. Therefore, surveillance CT to identify relapse would only be recommended when relapse is clinically suspected.

Table 1.

Characteristics at relapse according to method of detection

Characteristics at relapse	All (*n* = 171)	Group 1* (*n* = 104)	Group 2* (*n* = 67)	p-value
Biopsy-proven relapse, *n* (%)	109 (63.7)	72 (69.2)	37 (55.2)	0.063[a]

A MULTI-CENTER STUDY OF GLIDE CHEMOTHERAPY CONSOLIDATED WITH AUTOLOGOUS STEM CELL TRANSPLANTATION FOR NEWLY DIAGNOSED STAGE IV AND RELAPSED EXTRANODAL NATURAL KILLER/T-CELL LYMPHOMA PATIENTS

J. Ji[1,*], T. Liu[1], B. Xiang[1], Z. Liu[1], Y. Jia[1], Y. Lian[2], Z. Lin[3], F. Xu[4], W. Liu[5], H. Zhu[1], T. Niu[1], L. Pan[1], Y. Gong[1], H. Chang[1], J. Huang[1], Y. Wu[1], J. Li[1], C. He[1], L. Xie[1], H. Ma[1], Y. Tang[1], Y. Guo[1], P. Kuang[1], T. Dong[1]
[1]Hematology, West China Hospital of Sichuan University, [2]Hematology, Chengdu First People's Hospital, [3]Hematology, Affiliated Hospital&Clinical Medical College of Chengdu University, Chengdu, [4]Hematology, Mianyang Central Hospital, Mianyang, [5]Pathology, West China Hospital of Sichuan University, Chengdu, China

Background: The prognosis of advanced-stage and relapsed extranodal NK/T cell lymphoma(ENKTL) is poor, with long term survival rate of 30%. Our previous study of GLIDE (gemcitabine, L-asparaginase, ifosfamide, dexamethasone and etoposide) chemotherapy reported complete response(CR) rate and 3-year overall survival(OS) of these patients were 57.1% and 56% respectively. We assumed autologous stem cell transplantation may further improve the prognosis of these patients.
Aims: We conducted this clinical trial to address the efficacy and safety of our treatment strategy, GLIDE induction followed by ASCT, in newly diagnosed stage IV and relapsed ENKTL.
Methods: We treated 60 patients with newly diagnosed stage IV(n=49) and relapsed(n=11) ENKTL from 2010 to 2016. The median age at recruitment was 38 years and the median follow-up period was 13.4 months. Patients were treated with GLIDE (gemcitabine 800 mg/m^{2}D1,5; *L*-asparaginase 6000 u/m^{2}D4,6,8,10,12 or peg-asparaginase 2500 u/m^{2}D4,11; *i*fosfamide 1000 mg/m^{2}D1-3; *d*examethasone 20mg D1-4; *e*toposide 100 mg/m^{2}D1-3) every 4 weeks, and responses were evaluated with PET/CT every 2 cycles. Patients achieving CR underwent ASCT or continued with GLIDE up to 6 cycles. Others finished 6 cycles of GLIDE. Overall response rate(ORR), CR, OS and progression free survival(PFS) were calculated using standard methods. Statistical analysis was done using Fishers exact test or Chi-square test / Kruskal-Wallis test. Kaplan-Meier method was used for time-to-event analysis including overall survival and progression free survival. The Log-rank test was used to evaluate the difference in time-to-event endpoints between patient groups.
Results: Fifty-seven patients had finished planed treatment with 1 withdraw of informed consent after cycle 1, and 2 death of sepsis during cycle 1 and cycle 2 respectively. Twenty-one patients underwent ASCT. The ORR was 81.4% and the CR was 69.5% with early CR (CR after 2 cycles) of 57.6%. Estimated 5-year OS and PFS rates of the whole cohort and patients underwent ASCT were 68.7%, 54.0%, 79.6% and 85.2% respectively. Univariate analysis revealed that ECOG ≤1, IPI≤2, early CR and ASCT were associated with less relapse and death. Multivariate analysis showed ECOG ≥2 was an independent risk factor for disease progression (HR=4.321, 95% CI 1.127~16.572, P=0.033) and death (HR=46.254, 2.150~993.190, P=0.014) and ASCT was associated with better PFS (HR=0.058, 95% CI 0.007~0.495, P=0.009) and OS (HR=0.019,95% CI 0.001~0.596, P=0.024). Figure 1 highlights the OS and PFS of whole cohort (A) and ASCT patients (B). Myelosuppression was the most common adverse reaction(AE). The incidences of level 4 neutropenia, thrombocytopenia and anemia were 46.6%, 28.6% and 5.3% respectively. The most common non-hematologic AE was fever with neutropenia (36.5% of total cycles), while others were mild and manageable.

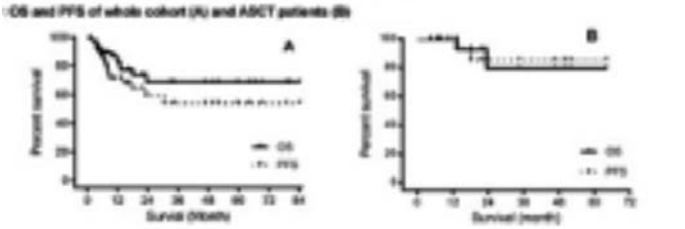

Figure 1.

Summary/Conclusions: GLIDE is an effective regiment for newly diagnosed stage IV and relapsed ENKTL. Up-front ASCT after achieving CR can reduce relapse and prolong survival. Treatment related adverse reactions and support care need concerns.

P225

LONG TERM FOLLOW-UP OF PATIENTS WITH PERIPHERAL T-CELL LYMPHOMAS TREATED WITH IFOSFAMIDE, ETOPOSIDE, EPIRUBICIN / INTERMEDIATE METHOTREXATE AND AUTOLOGOUS STEM CELL TRANSPLANTATION

M. Sieniawski[1,*], J. Lennard[1], S. Lyons[2], Z. Maung[3], P. Mounter[4], V. Hervey[2], R. Oakes[5], F. Keenan[4], A. Lennard[1]

[1]Newcastle upon Tyne Hospitals, NHS Foundation Trust, Newcastle upon Tyne, [2]City Hospitals Sunderland, NHS Foundation Trust, Sunderland, [3]North Tees and Hartlepool, NHS Foundation Trust, Stockton on Tees, [4]County Durham and Darlington, NHS Foundation Trust, Darlington, [5]North Cumbria University Hospitals NHS Trust, Carlisle, United Kingdom

Background: Despite improvement in the outcome for some subtypes of lymphoma, the prognosis of patients with peripheral T-cell lymphoma (PTCL) remains unsatisfactory. The recent data on dose-dense intensified cyclophosphamide, doxorubicine, vincristine and prednisone (CHOP) with addition of etoposide followed by autologous stem cell transplantation (ASCT) are encouraging. After achieving very promising results with in enteropathy associated T-cell lymphomas (EATL), we prospectively evaluated the alternative approach with more intensive treatment with ifosfamide, etoposide, epirubicin / methotrexate and ASCT (IVE/MTX–ASCT) in patients with other subtypes of PTCL.
Aims: To asses the long-term follow-up results of first line high-dose therapy IVE/MTX–ASCT in patients with PTCL.
Methods: The regimen was piloted for patients with a de-novo diagnosis of PTCL eligible for intensive treatment. The therapy delivers one cycle of CHOP, followed by 3 courses of IVE alternating with intermediate dose MTX. Stem cells are harvested after IVE and complete and partial remissions were consolidated with ASCT. The patients were evaluated with an intention-to-treat analysis for feasibility, response, progression free survival (PFS) and overall survival (OS) and late events.
Results: 30 patients were included: 17 peripheral T-cell lymphoma NOS, 6 anaplastic large cell lymphoma (ALCL) ALK positive, 4 extranodal NK/T-cell lymphoma nasal type, 2 ALCL ALK negative and 1 hepatosplenic T-cell lymphoma. The median age at diagnosis was 42 years (range 22 – 64), 37% patients were female, 28% presented with ECOG >1 and 57% with advanced stage disease. The age adjusted IPI was calculated for 22 patients with primary nodal disease and 41% of patients were in high intermediate and high risk. Three patients discontinued treatment prematurely due to disease progression and one due to poor general condition. Of the remaining 26 patients 19 went on to receive ASCT. ASCT was omitted due to: insufficient stem cell mobilisation in 4 patients, refractory disease in 2 and poor general condition in one. Toxicity was acceptable for such an intensive regimen. At final evaluation, complete remission (CR) was confirmed in 23/30 (77%) patients and partial remission (PR) in 2/30 (7%) patients. When the patients with ALCL ALK positive were excluded, the remission rates remained the same: CR 18/24 (75%) and PR 2/24 (8%); p>.999. During the study time 13/30 (43%) patients died, 11 due to lymphoma. For all patients 5-years PFS was 57% and OS 63%. These results were unchanged after the exclusion of ALCL ALK positive: 50% and 58%; p=.587 and p=.70; respectively. The 5-year PFS and OS of histological subgroups were as follows: ALCL, ALK positive: both 83%, PTCL NOS: 47% and 53%, ALCL, ALK negative: 0% and 50%, extranodal NK/T-cell lymphoma, nasal type: both 100% and for hepatosplenic T-cell lymphoma: both 0%. During the median follow-up time of 6.35 years, 13 patients had a relapse of underlying disease, six of them had received no treatment and died shortly after the diagnosed of relapse, further six received systemic chemotherapy and in one patient no information on relapse treatment was available. Among the six patients treated with systemic chemotherapy four received curative treatment including high-dose chemotherapy with allogenic stem transplant (alloSCT) in three patients and two received palliative treatment. Only two patients who received dexamethasone, high-dose cytarabine and cisplatin (DHAP) followed with alloSCT achieved a long lasting remission. Seven years post IVE/MTX-ASCT one patient developed secondary malignancy ALM/MDS and died shortly after the diagnosis.
Summary/Conclusions: IVE/MTX-ASCT significantly improves outcome in patients with PTCL, and has acceptable toxicities. Where feasible patients with PTCL could be considered for aggressive treatments, like IVE/MTX–ASCT as primary therapy, further studies are required.

IDENTIFICATION OF A NOVEL GERMLINE MECOM / EVI1 VARIANT THAT RUNS IN A PEDIGREE WITH RADIOULNAR SYNOSTOSIS AND AMEGAKARYOCYTIC THROMBOCYTOPENIA AND PREDISPOSES TO ADULT ONSET MYELOID MALIGNANCY

T. Ripperger[1,*], W. Hofmann[1], J.C. Koch[2], K. Shirneshan[3], D. Haase[3], G. Wulf[3], P.R. Issing[4], M. Karnebogen[5], G. Schmidt[1], B. Auber[1], B. Schlegelberger[1], T. Illig[1,6], B. Zirn[7], D. Steinemann[1]
[1]Department of Human Genetics, Hannover Medical School, Hannover, [2]Department of Neurology, [3]Department of Hematology and Oncology, University Medical Centre, Goettingen, [4]Department of Otorhinolaryngology, Head, Neck and Facial Plastic Surgery, Klinikum Bad Hersfeld, Bad Hersfeld, [5]Healthpark Lenglern, Division of Surgery and Orthopedics, Bovenden, [6]Unified Biobank, Hannover Medical School, Hannover, [7]Genetic Counseling and Diagnostics, Genetikum, Stuttgart, Germany

Background: Radioulnar synostosis and amegakaryocytic thrombocytopenia (RUSAT), one of the rare bone marrow failure syndromes, is caused by a point mutation in *HOXA11*. In three simplex patients, *de novo* missense variants in *MECOM* have recently been reported as an alternative cause in individuals with RUSAT. *MECOM*, identified as a common ecotropic viral integration site 1 (*EVI1)* in murine myeloid leukemia, is known as a key transcriptional regulator in hematopoiesis and is frequently involved in sporadic myeloid leukemia.
Aims: To screen for the causative genetic alteration in a family with four affected individuals out of three generations with radioulnar synostosis, incompletely penetrant congenital thrombocytopenia, hearing impairment due to dysplastic middle ear bones, patellar hypoplasia, and hand and foot dysmorphisms. Notably, two of four affected individuals in our family developed adult onset myeloid malignancies (*i.e.* myelodysplastic syndrome (MDS) with excess blasts and MDS/myeloproliferative neoplasm-unclassifiable). No *HOXA11* mutation was identified in this family.
Methods: Whole exome sequencing was performed in three affected individuals using a *Nextera Rapid Capture kit* and a *NextSeq 500* instrument (Illumina, Munich, Germany). Identified sequence variants were filtered for those that are (i) called in all three subjects, (ii) predicted to be damaging (SIFT, Polyphen, and MetaLR), (iii) reported to have an allele frequency of ≤0.1% (1000G, ESP6500, ExAc), and (iv) not listed in our in-house database of recurrent variants.
Results: Following this approach, a novel MECOM missense variant (*i.e.* Cys766Gly, UniProtKB Q03112-1) was identified. The missense mutation affects a heavily conserved cysteine residue in C_2H_2-zinc finger motif 9 in the C-terminal zinc finger domain of MECOM. This residue is crucial for the tetrahedral coordination of a zinc ion stabilizing the zinc finger conformation and thus, is essential for DNA binding of the C-terminal zinc finger domain.
Summary/Conclusions: Our findings confirm the causality of *MECOM* missense mutations targeting the C-terminal zinc finger domain in subjects with RUSAT and indicate that *MECOM* needs to be considered in RUSAT pedigrees with no *HOXA11* mutation. We report here for the first time that *MECOM* germline mutations are associated with an increased risk for adult onset myeloid malignancies. This extends the RUSAT-associated phenotype and proposes that *MECOM* germline mutations can cause a genetic predisposition to adult onset myeloid malignancy.

LOSS OF THE HOMOLOGOUS RECOMBINATION GENE RAD51 LEADS TO FANCONI ANEMIA-LIKE SYMPTOMS IN ZEBRAFISH

J. Botthof[1,2,3,*], E. Bielczyk-Maczyńska[1,2,4], L. Ferreira[1,2,3], A. Cvejic[1,2,3]
[1]Department of Haematology, University of Cambridge, [2]Wellcome Trust Sanger Institute, [3]Wellcome Trust-Medical Research Council Cambridge Stem Cell Institute, University of Cambridge, [4]NHS Blood and Transplant, Cambridge, United Kingdom

Background: Fanconi anemia (FA) is a hereditary DNA repair disorder characterized by various congenital abnormalities, progressive bone marrow failure and cancer predisposition. *RAD51* has recently been designated as a Fanconi anemia (FA) gene, following the discovery of two patients carrying dominant negative mutations. RAD51 is an indispensable homologous recombination protein, necessary for strand invasion and crossing over. It has been extensively studied in prokaryotes and lower eukaryotes. However, there is a significant lack of knowledge of the role of this protein and its regulation in an *in-vivo* context in vertebrates due to the early embryonic lethality of murine *Rad51* mutants.
Aims: Here we aim to utilize the powerful genetics and translucency of zebrafish to dissect the role of *rad51* in hematopoiesis and to explore the molecular basis of Fanconi anemia pathogenesis.
Methods: Zebrafish carrying homozygous loss of function mutations in *rad51*

generated by ENU mutagenesis were characterized in terms of their hematopoietic and non-hematopoietic phenotypes during embryonic development and adulthood.
Results: The *rad51* mutant fish developed key features of FA, including hypocellular kidney marrow (equivalent to mammalian bone marrow), sensitivity to crosslinking agents and decreased size. Interestingly, although mutants can survive to adulthood, they develop exclusively as sterile males. We show that some of the hematological symptoms stem from both decreased proliferation and increased apoptosis of embryonic hematopoietic stem and progenitor cells. Co-mutation of *p53* was able to rescue the embryonic and adult hematopoietic defects seen in the single mutants, but led to early tumor development in the adult double mutants. We further establish that prolonged inflammatory stress can exacerbate the hematological impairment, leading to an additional decrease in kidney marrow cell numbers linked to excess *p53* expression (Figure 1).

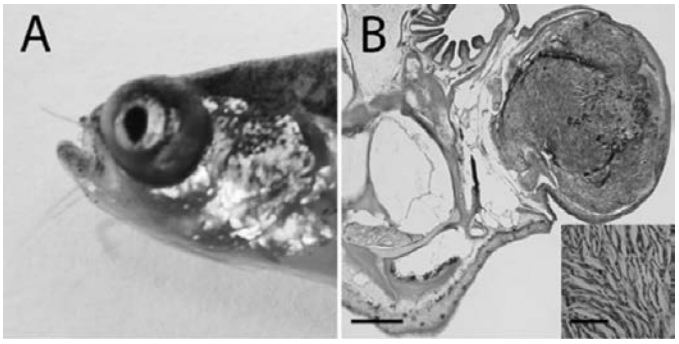

Figure 1. Example image of a p53, rad51 double mutant fish with a tumor behind the eye (A). Histological analysis showed the tumour to be a malignant peripheral nerve sheath tumor (B). The scale bar is 500 and 10µm respectively.

Summary/Conclusions: We demonstrate that zebrafish lacking functional *rad51* are viable and develop symptoms resembling FA. These findings strengthen the assignment of *RAD51* as a Fanconi gene and provide more evidence for the notion that aberrant p53 signaling during embryogenesis leads to the hematological defects seen during later stages of life in FA patients. Further research on this novel zebrafish FA model will lead to a deeper understanding of the molecular basis of bone marrow failure in FA and the cellular role of the RAD51 protein.

A NOVEL TELOMERASE RNA COMPONENT VARIANT IN A FAMILY WITH MACROCYTOSIS AND MILD VARIABLE CYTOPENIAS

C. Burney[1,*], A. Mumford[2], N. Roy[34], S. Henderson[3], M. Proven[3], A. Schuh[3], K. Wray[4], H. Dreau[3], C. Bradbury[2]
[1]Department of Haematology, University Hospitals Bristol NHS Trust, [2]School of cellular and molecular medicine, University of Bristol, Bristol, [3]BRC Blood Theme and BRC/NHS Translational Molecular Diagnostics Centre, John Radcliffe Hospital, [4]Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, John Radcliffe Hospital, Oxford, United Kingdom

Background: Telomerase RNA component (TERC), encoded by the *TERC* gene, is an essential component of telomerase, a polymerase that adds the telomeric repeat to the 3' lagging strand of DNA during cell replication. *TERC* variants have been causally associated with several haematological disorders, including autosomal dominant dyskeratosis congenita (DKC), aplastic anaemia, myelodysplastic syndrome and acute leukaemia, sometimes accompanied by non-haematological phenotypes. Here we report a likely pathogenic *TERC* variant associated with a haematological phenotype that predominantly affects the red cell lineage.
Aims: To describe the genotypic and phenotypic relationship of a new *TERC* variant.
Methods: Genomic DNA samples were analysed for sequence variants using the Oxford Red Cell Panel, a panel of 33 genes previously associated with human red cell disorders. Sanger sequencing was used to confirm the genetic variant. Telomere lengths were performed at the Laboratory for Molecular Haemato-Oncology (LMH), Rayne Institute, Kings College Hospital.
Results: The index case AM (I.1) was a female who presented at age 56 with fatigue, and was noted to have a longstanding non progressive mild macrocytic anaemia with very minimal thrombocytopenia. Further investigations (Table 1) revealed normal reticulocyte count, LDH, haematinics, thyroid function, liver and renal function. Bone marrow aspirate demonstrated abnormal erythropoiesis with nucleo-cytoplasmic asynchrony, nuclear atypia, ragged cytoplasm, basophilic stippling and bi-nucleate forms. Granulopoiesis and megakaryopoiesis were normal. The two daughters of I.1 also had abnormal blood counts and her paternal grandfather died of "pernicious anaemia". None of the family have somatic features associated with DKC. The elder daughter (age 30) TW (II.1), had isolated lifelong macrocytosis and previous mild neutropenia (Table 1). The younger daughter (age 27) BM (II.2) had macrocytic anaemia, thrombocytopenia (Table 1) and a recent pregnancy complicated by worsening thrombocytopenia, pre-eclampsia, placental dysfunction, liver dysfunction and foetal loss. Following delivery her liver function slowly returned to normal and a fibroscan was within normal limits. All three pedigree members with macrocytosis had a Chr3:169482668 (GRChr37) single nucleotide variant corresponding to a n.181A>C substitution in *TERC* (relative to transcript ENST00000602385.1), within the pseudoknot domain. Residue n.181 is highly conserved across mammalian species. This variant is absent from the gnomAD database of more than 230,000 *TERC* alleles, and the HGMD databases. The variant is within a *TERC* region in which previously reported variants have been associated with haematological phenotypes. In order to determine the pathogenicity of this variant, telomere lengths were assessed and found to be short in both Case I.1 and II.2 (Table 1). There were no other likely pathogenic variants in the Oxford Red Cell Panel genes. Together, these observations suggest that the n.181A>C substitution is causally associated with the macrocytosis phenotype.

Table 1.

Parameter (normal range)	I.1 (index case)	II.1	II.2
Haemoglobin (120-150g/l)	94g/l	120g/l	100g/l
Mean cell volume (83-100fL)	111.6fL	106.0fL	107.4fL
Mean cell haemoglobin (27-32pg)	33.3pg	34.1pg	33.6pg
Total white cell count (4-10x10^9/l)	4.36x10^9/l	6.83x10^9/l	5.07x10^9/l
Neutrophils (1.5-7.5x10^9/l)	2.3x10^9/l	5.4x10^9/l	2.3x10^9/l
Lymphocytes (1-4x10^9/l)	1.51x10^9/l	1.15x10^9/l	2.05x10^9/l
Monocytes (0.52-1x10^9/l)	0.48x10^9/l	0.32x10^9/l	0.52x10^9/l
Eosinophils (<0.51x10^9/l)	0.06x10^9/l	0.11x10^9/l	0.18x10^9/l
Basophils (<0.11x10^9/l)	0.01x10^9/l	0.01x10^9/l	0.02x10^9/l
Platelets (150-400 x10^9/l)	143x10^9/l	187x10^9/l	91x10^9/l
Reticulocytes (50-100x10^9/l)	85x10^9/l	53.7x10^9/l	86.1x10^9/l
Serum erythropoietin (3-18mIU/ml)	-	-	504.9mIU/mL
Blood film appearance	Anisopoikliocytosis, macrocytosis, irregularly contracted cells, polychromasia, large platelets	Macrocytosis only	Anisopoikliocytosis, macrocytosis, large platelets
Telomere length analysis (compared to normal individuals of the same decade of age)	Short telomere length, <1st percentile	-	Short telomere length, <1st percentile

Representative laboratory test results

Summary/Conclusions: This report demonstrates a likely causal association between a newly identified *TERC* variant, short telomere length and a relatively mild haematological phenotype that is largely restricted to red cells. This emphasises the phenotypic heterogeneity associated with *TERC* variants, justifies the rationale of screening multiple genes simultaneously and suggests that *TERC* variant could potentially underlie a broader range of unexplained heritable blood cell abnormalities.

P229

GENERATION OF X-LINKED DYSKERATOSIS CONGENITA-LIKE HUMAN HEMATOPOIETIC STEM CELLS

C. Carrascoso[1,2], H.A. Zittersteijn[1,2], L. Pintado-Berninches[2,3], M.L. Lozano[1,2], L. Sastre[2,3], J.A. Bueren[1,2], R. Perona[23], G. Guenechea[1,2,*]
[1]División of Hematopoietic Innovative Therapies, Centro de Investigaciones Energéticas Medioambientales y Tecnológicas (CIEMAT) and Instituto de Investigación Sanitaria Fundación Jiménez Díaz (IIS-FJD/UAM), [2]Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), [3]Instituto de Investigaciones Biomédicas Alberto Sols (CSIC/UAM), Madrid, Spain

Background: X-linked Dyskeratosis congenita (X-DC) is an inherited syndrome caused by mutations in the *DKC1* gene that encodes for the dyskerin nucleolar protein. These mutations reduce the telomerase activity leading to premature telomere length attrition. Several organs can be affected in these patients, although the bone marrow failure (BMF) is the main cause of death in X-DC patients (more than 70% of cases). So far, the only curative treatment for BMF in DC patients is hematopoietic stem cell (HSC) transplantation. However, risks derived from conditioning regimes and the difficulties to find a compatible donor suggest that gene therapy may constitute a promising alternative in treating DC patients.

Aims: Because of the difficulties associated to the use of primary HSCs from DC patients for experimental studies, this study was focused on the generation of X-DC-like human HSCs by means of the down-regulated expression of dyskerin in cord blood HSCs using different anti-*DKC1* short hairpin RNAs (shRNA).
Methods: CD34+ cells were obtained by immunomagnetic purification from healthy human umbilical cord blood samples. These cells were then pre-stimulated and exposed to two cycles of transduction with lentiviral vectors carrying both an anti-*DKC1* shRNA and the puromycin-resistance gene. Transduced samples were then selected for 2 days with puromycin, and cultured *in vitro* or transplanted into immunodeficient NSG mice to evaluate the effects of shRNAs.
Results: Based on the inhibition of *DKC1* gene expression, 3 shRNAs were selected among 7 designed shRNAs. Interfered HSCs showed an inhibited telomerase activity, as well as a reduced clonogenic and hematopoietic reconstitution potential in NSG mice. Additionally, an increase in DNA damage and senescence was observed in *DKC1*-interferred CD34+ cells.
Summary/Conclusions: *In vitro* and *in vivo* data obtained from *DKC1*-interferred CD34+ cells show that these cells mimic the phenotype of primary X-DC-HSCs. The generation of X-DC-like HSCs will facilitate the understanding of the molecular basis of the HSC defects characteristic of X-DC and contribute to the development of new experimental therapies for the treatment of the BMF of X-DC patients.

P230

STUDY OF EXTRACELLULAR VESICLES ROLES IN THE PATHOPHYSIOLOGY OF THROMBOSIS IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA PATIENTS DURING ECULIZUMAB TREATMENT: A PILOT PROSPECTIVE LONGITUDINAL CLINICAL STUDY

A. Wannez[1,2,*], B. Devalet[2], C. Bouvy[1], B. Bihin[3], J.-M. Dogné[1], F. Mullier[2]
[1]Department of Pharmacy, University of Namur, Namur, [2]CHU-UCL Namur, Université catholique de Louvain, [3]Scientific Support Unit, CHU-UCL Namur, Yvoir, Belgium

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a disease characterized by complement-mediated hemolysis (Brodsky *et al.* Hematology, 2008). Complement can induce the production of extracellular vesicles (EV) (Burnouf *et al.* Transfus Apher Sci, 2015). These EV are cell-derived vesicles whose the size-range is around 50 and 1000nm. They can expose phosphatidylserine (PS-anionic phospholipid) and tissue factor (TF), which explains their involvement in the coagulation cascade (Owens *et al.* Circ Res, 2011). The EV could have a role in the thrombus formation, the leading cause of death in PNH patients (Brodsky *et al.* Hematology, 2008; Simak *et al.* Br J Haematol, 2004; Hugel *et al.* Blood, 1999). Eculizumab, a human anti-C5 monoclonal antibody, used in the treatment of PNH seems to decrease the thrombosis frequency (relative reduction of 85% of thromboembolism event rate with the introduction of the treatment in the patients) (Hillmen *et al.* Blood, 2007; Kelly *et al.* Ther Clin Risk Manag, 2009; Weitz *et al.* Thromb Res, 2012; Al-Jafar *et al.* Hemato Rep, 2015).
Aims: The general purpose of this project is a better understanding about the role of EVs in thrombosis in the context of PNH patients under eculizumab. We assessed the impact of eculizumab on the EV quantification and on their procoagulant activity, in order to check, if the antithrombotic activity of the eculizumab could be in part explained by its interaction with the EVs.
Methods: We conducted a pilot prospective open label longitudinal clinical study with six PNH patients treated with eculizumab. The study was led according to the declaration of Helsinki and approved by the local Ethic Committee. Informed consent was obtained for each patient. The aim was to measure, by flow cytometry, the production of EVs in patient's platelet-free plasma (PFP) before the start of eculizumab, after 4 weeks and after 11 weeks of treatment. We also assessed the procoagulant activity in PFP by STA®-Procoag-PPL assay and by thrombin generation assay (TGA). A more sensitive version of TGA was also performed to study the procoagulant profile induced by the EVs (use of EVs pelleted from PFP). We used mixed-effects linear regression (R 3.1.2 with nlme package) with logarithmic transformation for flow cytometry results. We compared the results after 4 weeks or 11 weeks of treatment against the inclusion value.
Results: We observed a decrease in platelet EVs with the eculizumab treatment ($p<0.05$). STA®-Procoag-PPL assay showed a decrease of the procoagulant profile induced by procoagulant phospholipids (PL) with the treatment. These results were not confirmed by TGA on PFP, due to a lack of sensitivity. By this way, we performed a more sensitive version of TGA that allows to observe variation in the procoagulant profile induced by the EV with the eculizumab ($p<0.05$).
Summary/Conclusions: Eculizumab has an impact on the amount and the procoagulant profile induced by the procoagulant PL and the EVs. The anti-thrombotic performance of the eculizumab can be in part explained by its action on EVs.

P231

TELOMERE LENGTH SCREENING TRIGGERED BY CLINICAL SUSPICION FOR CLASSICAL AND/OR CRYPTIC DYSKERATOSIS CONGENITA – PROSPECTIVE RESULTS FROM THE AACHEN TELOMEROPATHY REGISTRY

F. Beier[1,*], M. Kirschner[1], A.-S. Bouillon[1], I. Halfmeyer[1], M.S. Ventura Ferreira[1], A. Maurer[1], S. Wilop[1], F. Thol[2], A. Röth[3], U. Platzbecker[4], W. Blau[5], F. A. Ayuk[6], S. Corbacioglu[7], H. Schrezenmeier[8], M. G. Manz[9], T. Eggermann[10], K. Zerres[10], S. Koschmieder[1], M. Schmemionek[1], S. Isfort[1], J. Panse[1], T.H. Brümmendorf[1]
[1]Department of Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, Medical Faculty, RWTH Aachen University, Aachen, [2]Department of Hematology, Hemostasis, Oncology, and Stem Cell Transplantation, Hannover Medical School, Hannover, [3]Department of Hematology, West German Cancer Center, University Hospital Essen, University of Duisburg-Essen, Essen, [4]Department of Internal Medicine I, University Hospital Carl Gustav Carus, Dresden, [5]Department of Haematology and Oncology, Justus-Liebig Universität, Giessen, [6]Department of Stem Cell Transplantation, University Medical Center Hamburg-Eppendorf, Hamburg, [7]Department of Pediatric Hematology, Oncology and Stem Cell Transplantation, University of Hospital Regensburg, Regensburg, [8]Institute of Transfusion Medicine, University of Ulm, Ulm, Germany, [9]Department of Hematology and Oncology, University and University Hospital Zürich, Zürich, Switzerland, [10]Institute of Human Genetics, Medical Faculty, RWTH Aachen University, Aachen, Germany

Background: *Classical* Dyskeratosis Congenita (DKC) is a multisystem disorder caused by defective telomere maintenance, mostly due to mutations in genes related to functional activity of telomerase or accessibility of the telomeres themselves. Clinical characteristics are mucocutaneous abnormalities, bone marrow failure, an increased predisposition to cancer and other variable features. While *classical* DKC is typically diagnosed in childhood or adolescence, the incidence of *cryptic* DKC variants typically presenting with a clinically more heterogeneous picture also involving the liver, gut and respiratory system in adults up to 50 years of age is unknown. Accelerated shortening of Telomere length (TL) in peripheral blood leucocytes represents the functional read-out of altered telomere maintenance and thus allows for a screening of patients with suspected DKC. On the basis of TL measured below the 1% percentile of age adjusted healthy controls, next-generation-sequencing (NGS) analysis for underlying mutations was triggered.
Aims: In this study, we report the first results of such a clinical routine screening for telomeropathies carried out within the Aachen Telomeropathy Registry (ATR).
Methods: 184 patients from 52 participating centers (80% academic centers) within Germany, Austria and Switzerland were screened for premature telomere shortening and included with informed consent into the ATR since November 2014. Inclusion criteria and reason for screening was either the clinical suspicion of the treating physician for a telomere maintenance disorder and/or the recommendations of the German Society of Hematology and Oncology (DGHO) published via *Onkopedia*. TL analysis of peripheral blood granulocytes and lymphocytes was carried out using combined fluorescence *in situ* hybridization and flow cytometry (flow-FISH). Mutations in genes suspected to cause telomeropathies (*i.e.* TERT, TERC, DKC1, NOP10, NHP2, USB1, CTC1, RTEL1, TIN2, TCAB1) were analyzed by NGS using customized primer panels and amplicon-based sequencing on a Miseq sequencer (Illumina) in all patients with TL in lymphocytes below the 1% percentile of healthy controls.
Results: Underlying initial diagnosis by the treating physician leading to TL screening were aplastic anemia (AA, n=72, 39% of cases), unexplained cytopenias (UC, n=21, 11%), myelodysplastic syndrome (MDS, n=18, 10%), family members (FM) of known DKC patients (FM-DKC, n=17, 9%), atypical squamous cell cancer of the head-and-neck (SCCHN, n=10, 6%), paroxysmal nocturnal hemoglobinuria (PNH, n=9, 5%), acute myeloid leukemia (AML, n=5, 3%) as well as other disorders (*e.g.* lung fibrosis, Diamond-Blackfan-Anemia, Dubowitz-syndrome, etc., n=32, 17%). Median age was 41.5 y (range from 0.5 to 88 y). TL screening revealed 20% (38/184) patients with lymphocyte TL and 16% (30/184) of patients with granulocyte TL below the 1% percentile. NGS screening identified typical mutations associated with altered telomere maintenance in 15 out of 38 patients (40%) representing 8,2% of the total patient population. Median age of patients with mutations was 45.0 y (range 21 to 68 y). Mutations were detected in RTEL1 (n=3), TERC (n=6), TERT (n=3) and DKC1 (n=3). Mutations were observed in 5% of all AA, 12% of all UC, 50% of all FM-DKC, 13% of all SCCHN, 20% of all screened AML patients.
Summary/Conclusions: We provide the first analysis of a routine TL screening program (within the ATR) for clinically suspected telomeropathy in patients up to the age of 88 y. TL screening is feasible in a routine clinical setting identifying approximately 20% of all samples to reside below the 1% percentile. Genetic testing confirmed the diagnosis of *cryptic* DKC in a variety of initial diagnoses. This study highlights both the diagnostic value of TL screening for *cryptic* DKC as well as its underrated incidence in adults. Proper diagnosis of DKC however is of utmost importance given its significant individual clinical implications towards prognosis, treatment and family counseling.

P232

TRANSPLANTATION IN PATIENTS WITH ACQUIRED APLASTIC ANEMIA OVER THE AGE OF 40: MORTALITY HAS NOT BEEN REDUCED IN 2010-2015

S. Giammarco[1,*], S. Simona[2], C. Dufour[3], R. Peffault de Latour[4], G. Socie[5], J. Passweg[6], A. Bacigalupo[1]
[1]Hematology, Università Cattolica del Sacro Cuore, Rome, [2]Hematology, Uni-

versità Cattolica del Sacro Cuore, roma, [3]Hematology, Istituto Giannina Gaslini, Genova, Italy, [4]Hematology, Hopital St Louis, [5]Hematology, Hopital Saint-Louis, Paris, France, [6]Hematology, Universitätsspital Basel, Basel, Switzerland

Background: Mortality following HSCT in SAA pts over the age of 40 is reported to be in the order of 50%, without taking in to account long term sequelae such as chronic GvHD, known to be more frequent in older patients. This has prompted international guidelines to recommend first line immunosuppressive therapy above 40 years of age. The question is whether this is still true in 2017.

Aims: Assess whether TRM in SAA patients grafted 2010-2015 is reduced, as compared to the era 2001-2009.

Methods: We used the WPSAA EBMT registry, and identified 748 pts aged 40 years or more, with acquired SAA, grafted between 2001 and 2015. We divided pts in 2 transplant eras:2001-2009 (n=327) and 2010-2015 (n=407). In the more recent period (2010-2015) pts were older (53 *vs* 49 year, p<0.01), were more often grafted from alternative donors (ALT) (64% *vs* 43%, p<0.01), with a greater use of BM (54% *vs* 41%, p<0.01), and with a longer interval dx-tx (317 *vs* 258 days , p0.01), and more often received a fludarabine containing regimen (55% *vs* 42%, p<0.01).

Results: The overall survival 5 year survival of pts grafted in 2001-2009 was 57% , compared with 55% for pts grafted 2010-2015 (p-=0.7). In multivariate analysis, including the interval diagnosis transplant, patient's age, donor type, stem cell source and conditioning regimen, the lack of improved survival in 2010-2015 was confirmed (p=0.3).A very strong age effect was shown both in univariate and multivariate analysis: survival of pts aged 40-50 years, 51-60 years and >61 years , was respectively 64%, 54%, 41% (p<0.0001) and this was confirmed in multivariate analysis. The conditioning regimen , also proved to be a significant predictor, with improved survival for ALT transplants receiving FLU containing regimens (56% *vs* 46%, p<0.001). In general pts receiving either CY200 or a FLU containing regimen , did significantly better than pts receiving other preparative regimens (58% *vs* 50%, p=0.02). The use of a sibling donor (SIB) did not prove to predict survival in multivariate analysis. Pts receiving Campath in the conditioning , did significantly better than pts not receiving Campath (65% *vs* 54% p<0.01); similarly survival of patients with ATG was superior 59% *vs* 41% compared to patients not receiving ATG (p<0.01). When pts receiving either Campath or ATG (n=564) were compared to patients not receiving either (n=161), the difference in survival was 61% *vs* 41% (p<0.0001), and this was significant also in multivariate analysis. Combined primary and secondary graft failure was reduced from 16% to 12% in the two time periods (p=0.02), acute GvHD grade II-IV was reduced from 15% to 11% (p=0.1) and chronic GvHD was also reduced from 32% to 26% (p=0.04) Infections remain the leading cause of death in both transplant eras (18% and 22% respectively), followed by GvHD (5% and 4%) and graft failure (5% and 2%), whereas PTLD have been reduced from 3% to 0,5% (Figure 1).

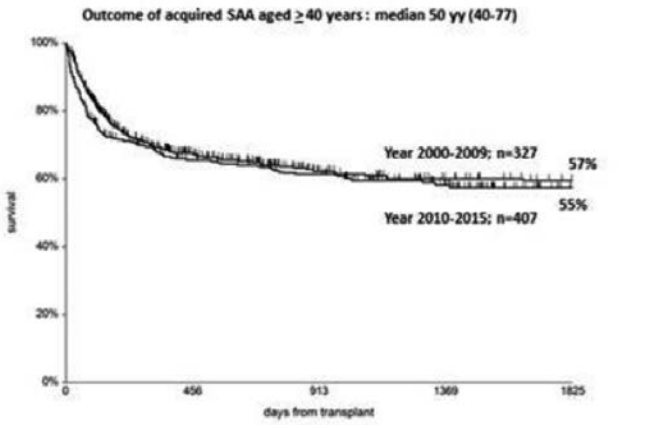

Figure 1.

Summary/Conclusions: HSCT in pts with acquired SAA aged 40 and over, continues to carry a significant risk of TRM also in 2010-2015, ranging from 36% in younger pts (40-50) to 59% in older pts (>60 years). Survival is predicted in multivariate analysis, by two crucial predictors:patients age and the use of either Campath or ATG,the latter giving a 20% survival advantage over no Campath /ATG. ALT and SIB donors produce similar survival. This study gives further support to current guidelines, suggesting first line therapy with ATG+CsA, in pts over the age of 40.

P233

CLINICAL AND GENETIC DIVERSITY IN DIAMOND-BLACKFAN ANAEMIA: AN UPDATE FROM THE UNITED KINGDOM

D. Iskander[1,*], C. Miller[2], M. Alikian[3], Y. Harrington [2], Q. Al-Oqaily[1], I. Roberts[4], A. Karadimitris[1], J. de la Fuente[5]

[1]Centre for Haematology, Imperial College London, [2]Department of Paediatrics, St. Mary's Hospital, Imperial College Healthcare Trust, [3]Imperial Molecular Pathology Laboratory, Imperial College Healthcare Trust and Academic Health Sciences Centre, London, [4]Department of Paediatrics, Children's Hospital and Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, Oxford University and John Radcliffe Hospital, Oxford, [5]Department of Paediatrics, St. Mary's Hospital, Imperial College Healthcare Trust, London, UK, London, United Kingdom

Background: Diamond-Blackfan anaemia (DBA) is an inherited bone marrow failure syndrome (IBMFS) caused by mono-allelic, loss-of-function mutations in ribosomal protein (RP) genes. DBA is rare and has a wide spectrum of clinical manifestations, hence the utility of patient registries.

Aims: We evaluated the clinical and genetic spectrum of DBA in a large cohort of patients in the UK, aiming to identify novel features of the disease.

Methods: We performed a retrospective analysis of data from 103 confirmed cases of DBA, including 4 multiplex families. All living patients had undergone at least one assessment at our specialized centre in the last 5 years. Data were collected from family interviews, patient records and referring clinicians.

Results: The 103 patients with DBA were born in a 48-year period (1967-2015), *i.e.*, an incidence of 3 per million live births. Demographic and clinical characteristics are shown in Table 1. NGS analysis of 80 RP genes plus *GATA-1* identified pathogenic mutations in 71% of cases and 7 putative novel mutations, currently undergoing validation. To date, mutation screening of *both* parents has been performed in 32 families with DBA. Twenty-five mutations are sporadic while 7 are autosomal dominant; in 3 of the latter, the parent is a silent 'carrier' without anaemia. In one case of an affected child, the causative mutation was undetected in the peripheral blood of both parents but was present in 7/22 embryos generated for *in vitro* fertilisation, suggesting germline mosaicism. 80.5% of cases in our cohort presented within the first year of life. For the first time we report a high rate of perinatal problems in DBA. Prematurity +/- intrauterine growth restriction (IUGR) occurred in 31/87 (35.6%) of evaluable patients. Specific abnormalities included: hydrops fetalis (3/87), prematurity (22/87) and IUGR (16/87). In addition to congenital anomalies classically associated with DBA, we identified abnormalities of the spine and axial skeleton in 9.2% of patients. These did not correlate with a particular genotype. Our cohort exhibited multiple comorbidities, including some not previously reported to be associated with DBA: herniae (10.7%), neuropsychiatric (17.4%) and gastrointestinal (GI) disorders (25.7%). These complications were not associated with particular treatment regimens. In terms of the natural history of DBA, a lower proportion of our patients (22%) than previously reported in the literature (40%) were able to maintain a normal Hb on long-term steroids. Three patients failed a metoclopramide trial. In total there were 4 incidents of malignancy (MDS, B-ALL, BCC and cervical intraepithelial neoplasia) in 4 different patients. The lower incidence in our cohort compared with that reported by the North American DBA registry may be explained by differences in the median ages of the 2 cohorts (12y *versus* 18y, respectively) and the shorter follow-up of our patients.

Table 1.

Demographic and clinical characteristics of 103 patients with DBA in the United Kingdom.
Incomplete information was available for some individuals therefore the number of patients for whom data were available (*N=*) is included for each parameter.

Parameter	N (%) or median [range]	Parameter	N (%) or median [range]
Female/male	55/48	Congenital anomalies *N=98*	
		None	19 (19.4)
Ethnicity		Single anomaly	24 (24.5)
Caucasian	83	Multiple anomalies	55 (56.1)
African	3	➢ Cardiac	35 (35.7)
Asian	10	➢ Upper limb	33 (33.7)
Middle Eastern	3	➢ Axial skeleton including spine (confirmed on imaging)	9 (9.2)
Mixed	2	❖ Spina bifida	1
Caribbean	1	❖ Cervical spine fusion	3

Summary/Conclusions: This retrospective analysis of the UK's DBA cohort confirmed several findings from other registries but also revealed novel features, including a high prevalence of i) premature birth and neonatal complications ii) abnormalities of the axial skeleton and iii) neuropsychiatric disorders. Prospective longitudinal studies are warranted to better characterise these co-morbidities and to confirm whether they are intrinsic to DBA or arise as complications of treatment. Above all, the observed clinical heterogeneity in our cohort highlights the need for novel therapies that target the multisystem manifestations of DBA, not just the anaemia.

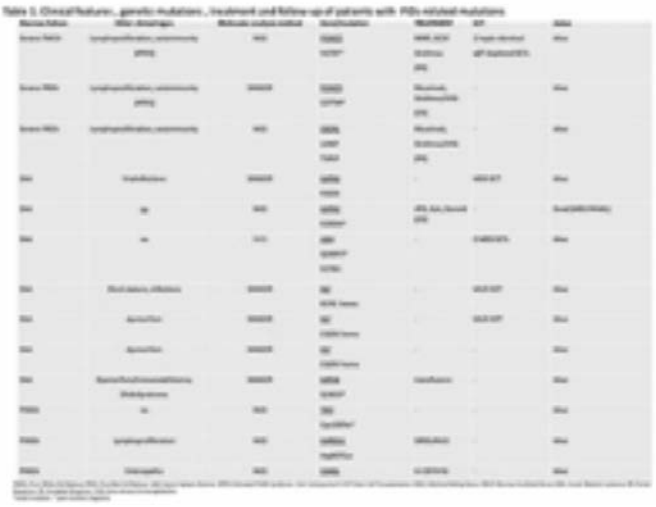
P234

BONE MARROW FAILURE SECONDARY TO NOVEL/KNOWN PRIMARY IMMUNODEFICIENCY-RELATED MUTATIONS. A SINGLE CENTER ANALYSIS

M. Miano[1,*], A. Grossi[2], L. Fanciullo[1], M. Lanciotti[1], F. Fioredda[1], E. Palmisani[1], F. Pierri[1], S. Giardino[3], E. Cappelli[1], T. Lanza[1], P. Terranova[1], M. Calvillo[1], C. Micalizzi[1], F. Giona[4], M. Santopietro[4], K. Zhang[5], I. Ceccherini[2], C. Dufour[1]
[1]Haematology Unit, [2]Molecular Genetic Unit, [3]Stem Cell Transplantation Unit, IRCCS Istituto Giannina Gaslini, Genova, [4]Haematology, Dep. of Cellular Biotechnologies and Haematology, La Sapienza University, Roma, Italy, [5]Division of Human Genetics, Cincinnati Children's Hospital Medical Center, Cincinnati, United States

Background: Differential diagnosis between acquired and congenital forms of Marrow Failure (MF), has always represented a crucial point in the diagnostic work-up, since genetic forms do require a different therapeutic approach. It is also known that patients with congenital MF may also show immunodeficiency that, in some cases, can represent the first/ or revalent sign of the disease and therefore can be misinterpreted as a Primary Immunodeficiency (PID). On the other hand, patients with PIDs may also show MF as a result of an immune-mediated attack of marrow precursors thus generating a phenotypic overlap that can impair the correct diagnosis.
Aims: In this report we analyzed all patients with MF evaluated in our Unit with the aim to identify the type and incidence of underlying molecular defects, in particular those related to PIDs.
Methods: We retrospectively evaluated all diagnosis performed in patients with single/multi-lineage MF followed in our Unit. DEB test was used to screen Fanconi Anemia (FA). Other congenital MFs have been searched by Sanger and/or NGS molecular analysis depending on the available tools over the years.
Results: Between 2009-2016, 88 patients have been studied for single-lineage (25) or multilieage (63) MF. 48 (54%) were classified as having an acquired MF, 27 (30%) were diagnosed with a congenital MF (FA 11, Diskeratosis Congenita 5, Severe Congenital Neutropenia 6, Blackfan-Diamond Anemia 3, Congenital Amegakaryiocitic Thrombocytopenia 2), and the remaining 13 patients (14%) were found to have an underlying PID. Table 1 shows clinical characteristics and mutations of patients with PIDs.

Table 1.



Summary/Conclusions: This report shows that patients presenting with single/multi-lineage MF may have an underlying PID in a considerable number of cases. We also show that MF represented the most relevant clinical sign in patients with PI3KCD, TACI, or CD40L mutations, thus widening their clinical phenotype. We conclude that an accurate immunological work-up should be performed in all patients with MF and that PIDs-related genes should be included in the molecular screening of MF in order to identify specific disorders that may potentially receive targeted treatment and/or the appropriate conditioning regimen for SCT.

P235

COVERSIN, A NOVEL C5 COMPLEMENT INHIBITOR, FOR THE TREATMENT OF PNH: RESULTS OF A PHASE 2 CLINICAL TRIAL

A. Hill[1,*], W. Weston-Davies[2], M. Nunn[2,3], T. Robak[4], A. Szmigielska-Kaplon[4], J. Windyga[5], A. Hellman[6]
[1]St James's Institute of Oncology, Leeds Teaching Hospitals, Leeds, [2]Akari Therapeutics Plc, [3]Haemostasis Research Unit, University College London, London, United Kingdom, [4]Department of Haematology, Medical University of Lodz and Copernicus Memorial Hospital, Lodz, [5]Department of Disorders of Haemostasis and Internal Medicine, Institute of Haematology and Transfusion Medicine, Warsaw, [6]Department of Haematology, Gdansk University Hospital, Gdansk, Poland

Background: Paroxysmal nocturnal haemoglobinuria (PNH) leads to episodic haemolysis secondary to an acquired deficiency of PIGA anchor molecules on the surface of erythrocytes which play a critical role in protecting the cells from complement mediated lysis. Until the advent of eculizumab, a monoclonal antibody which prevents the cleavage of C5 to C5a and C5b, PNH was associated with considerable morbidity and a poor long-term prognosis. However, eculizumab needs to be administered by health care professionals by intravenous infusion which may interfere with the life-styles, occupations and personal privacy of patients and the interval dosing has led to concerning breakthrough haemolysis. Coversin is a protein suitable for small-volume subcutaneous (SC) injection which can be self-administered by patients.
Aims: The aim of this study is to investigate the safety and efficacy of the complement C5 inhibitor Coversin in the treatment of PNH.
Methods: A Phase 2 single arm open label trial of Coversin is currently ongoing under which patients, either newly diagnosed with PNH or who have not previously had access to complement inhibitors, are treated for 90 days. Coversin is supplied as a lyophilised powder, reconstituted with water for injection to give a buffered aqueous solution of Coversin 30mg/mL. The trial population consists of up to 10 adult patients with a diagnosis of PNH confirmed by flow cytometry. Treatment commences with an ablating regime (AR) consisting of a fixed dose of 60mg followed by 3 doses of 30mg q12 hours delivered by SC injection. After being suitably instructed patients are encouraged to self-inject the drug. Following the AR, a dose of 15mg q12 hours is given for a further 26 days when, if the patient's disease is well controlled, they switch to 30mg q24 hours for the remainder of the trial. The dose can be increased by two incremental steps according to a pre-specified algorithm for patients not satisfactorily controlled on the basis of serum lactate dehydrogenase (LDH) or clinical grounds at any time during the 90-day period. The primary endpoints are safety and reduction of serum LDH to ≤1.8 X the upper limit of normal (ULN) for the local laboratory. Secondary endpoints include LDH at 28, 60 and 90 days, terminal complement activity assessed by CH50 ELISA (Quidel®), sheep erythrocyte haemolysis assay, PK (free and bound Coversin levels), anti-drug antibodies (ADA) and quality of life.
Results: The trial is still ongoing and has currently enrolled 5 patients, four of whom remain on Coversin. Three patients have required single dose increases during the initial 28-day period, one of whom was later withdrawn when a comorbidity was suspected. Two patients have moved to a single daily dose. Updated results of these and any patients enrolled subsequently will be presented. To date 2 patients have achieved the primary efficacy endpoint, two have not yet reached the 28-day point. There have been no serious or significant adverse events and the drug has been well-tolerated. A few mild injection site reactions have been recorded but these appear to diminish with time. There has been no evidence of the formation of neutralising antibodies.
Summary/Conclusions: It currently appears that treatment with Coversin is safe and effective in controlling hemolysis in PNH and that patients are capable of self-administering the drug. Coversin may be an effective alternative for patients with PNH who prefer the independence of self-administration. The relatively short dose interval may also help to reduce breakthrough events due to trough levels of drugs administered at two weekly intervals or longer.

Background: CLL is a highly heritable cancer. Although GWAS have identified ~30 independent SNPs associated with CLL, these are estimated to account for only 19% of the inherited component of CLL.
Aims: We hypothesized that this missing heritability might arise from rare coding variants (MAF <0.01), and sought to identify these through an exome-wide association study comparing rare germline variants between CLL patients and controls.
Methods: We investigated 516 CLL patients of European descent who were compared to 8,920 ethnically matched, non-cancer population controls. CLL cohorts included 235 CLL patients from DFCI (128 previously reported, 107 unpublished exomes), and 281 CLL patients enrolled on the CLL8 trial of the German CLL Study Group (WES data reported previously). An additional 130 CLL patients in an extension cohort included 24 from our published whole-genome sequencing study and 106 from an early publication of the ICGC. Non-cancer controls came from 3 sources: 2,520 from the 1000 Genomes Project; 6,852 from the Exome Sequencing Project; and 7,611 from a study of genetic risk for myocardial infarction. We combined these heterogeneous datasets by: (i) processing sequencing data from all cohorts together and consistently; (ii) jointly calling the variants across all cases and controls; and (iii) analyzing only ethnically matched, unrelated samples over DNA sites with sequencing coverage sufficient to achieve high-confidence genotype calls. This quality control resulted in 8,920 controls available for the association analysis. We further controlled for residual population stratification by correcting for three principal components.
Results: Using an unbiased, gene-based rare variant association analysis comparing cases to controls, we identified two genes significantly enriched for rare coding variants in CLL cases: *CDK1* and *ATM* (OR 5.8, C.I.2.6-13.1, $p=5.8x10^{-7}$ and OR 1.6, C.I. 1.3-2.0, $p=1.4x10^{-6}$, respectively). *CDK1* variants were observed in 8 of 516 CLLs and 24 of 8,920 controls (1.6% *vs* 0.3%, OR=5.8, 95% CI 2.6-13.1). One recurrent missense variant, *CDK1* p.R59C, observed in 5 cases and 10 controls, is predicted to be possibly damaging by the PolyPhen2 prediction tool, and is driving the association. The second significant gene was *ATM*, in which we found a total of 112 cases carrying 52 distinct rare germline variants and 1296 controls carrying 292 rare variants (21.7% *vs* 14.5%; OR=1.6, 95% CI 1.3-2.0). The majority of recurrent rare variants in *ATM* were non-synonymous missense variants, with L2307F one of the most enriched (2.3% cases, OR=10.1, 4.9-20.7). Subsequent validation in 149 independent CLL cases revealed a similar frequency of 2.01% (3 out of 149) of the L2307F variant. We then added 130 CLL cases and performed an expanded joint analysis, which has been shown to improve the statistical power of detecting genetic associations compared to a two-stage replicate analysis. We identified 42 additional patients with rare *ATM* variants, and the significance of *ATM* was greatly increased (q=0.00016, OR 1.79, CI 1.49-2.15). We integrated somatic and germline sequencing data and found that patients with rare germline variants in *ATM* were more likely to harbor an additional *ATM* somatic lesion ($p=9.1x10^{-4}$). Furthermore, 80% of patients with both a rare germline variant in *ATM* and a somatic 11q deletion lost the wild-type *ATM* allele during deletion (p=0.012), suggesting that the germline variants behave as tumor suppressor alleles.
Summary/Conclusions: To our knowledge this analysis represents the first germline association analysis based on exome sequencing data in CLL, and our results implicate rare germline variation in *ATM* in CLL predisposition.

P237

DIFFERENTIAL ENHANCER TRANSCRIPTION ASSOCIATED WITH RISK ALLELE GENOTYPE IN CLL

B. Tesar[1,2], L. Werner[3], N. Pochet[4,5], S. Fernandes[1], M. R. Improgo[1,2], J. Klitgaard[1,2], C. Thompson[1], M. Hanna[4], A. Freedman[1], D. Neuberg[3], M. Freedman[2], L. Core[6], J. Brown[1,2,*]

[1]Department of Medical Oncology, Dana Farber Cancer Institute, [2]Department of Medicine, Harvard Medical School, [3]Department of Biostatistics and Computational Biology, Dana Farber Cancer Institute, Boston, [4]Broad Institute, Cambridge, [5]Department of Neurology, Harvard Medical School, Boston, [6]Department of Molecular and Cell Biology, University of Connecticut, Storrs, United States

Background: Genome-wide association studies (GWAS) have identified multiple loci that are statistically associated with CLL susceptibility. These single nucleotide polymorphisms (SNPs) are primarily located in non-protein coding genomic regions. Data suggest that these variants are enriched in regulatory elements.
Aims: We tested the hypothesis that CLL risk variants are in or near regulatory elements that influence nearby target genes.
Methods: To investigate SNP allele-specific impacts on gene expression, we selected 15 SNPs from 13 loci that achieved genome wide significance in initial CLL GWAS studies. We investigated either the published GWAS SNP (if present on the Affymetrix 6.0 SNP array) or proxy SNP(s) chosen using the SNP Annotation and Proxy Search (SNAP) software, based on their high linkage disequilibrium (LD) ($r^2>0.68$) with the selected GWAS SNP. Genotypes were determined in tumor (n=143) and saliva (n=79) DNA from CLL patients (who had provided written informed consent); tumor and saliva DNAs were concordant in at least 96% of cases (except rs477184 at 92%). Given the high concordance with saliva, which is likely related to the stable genome of CLL, SNP genotypes from tumor samples were used for the analysis in order to significantly increase our sample size. Allele-specific gene expression was then evaluated in tumor samples (n=143) using Affymetrix U133 Plus 2.0 array gene expression data, focusing on genes within 1 Mb in either direction from a given SNP. In order to elucidate whether these associations were due to functional effects on transcription, we used a novel assay called precision run-on sequencing (PRO-seq). PRO-seq efficiently maps active transcription regulatory elements (TREs) and provides a sensitive, quantitative and directional map of transcriptionally-engaged RNA polymerases. The algorithm, discriminative regulatory-element detection from GRO/PRO-seq (dREG), is then used to predict the presence of TREs from raw PRO-seq data, allowing for identification of functional elements in the vicinity of SNPs and quantification of their allele-specific effect on enhancer activity and gene transcription.
Results: Our gene expression analysis demonstrated 6 significant SNP-gene associations: rs674313 (6p21.3) with *HLA-DQA1* (p <0.0001), rs872071 (6p25.3) with *IRF4* (p=0.01), rs4777184 (15q23; proxy for rs7176508) with *TLE3* (p=0.009), rs783540 (15q25.2) with *CPEB1* (p=0.01), rs305088 (16q24.1; proxy for rs305061) with *COX4NB/EMC8* (p=0.03) and rs4802322 (19q13.32; proxy for rs11083846) with *FKRP* (p <0.0001). Two associations were successfully validated in a completely independent gene expression replication analysis (n=54): rs674313 with *HLA-DQA1* (p<0.0001) and rs4777184 with *TLE3* (p=0.0118). To annotate candidate regulatory elements, we evaluated transcription level at or near all six significant SNPs in the initial gene expression analysis in a cohort of 12 CLL samples. Transcription level at or near 3 SNPs (rs674313, rs4777184, rs305088) correlated with genotype in a dose dependent manner. When we expanded the analysis to the entire region of LD around each SNP, we were able to demonstrate a dose-dependent effect in all SNPs except rs872071.
Summary/Conclusions: We conclude that PRO-seq and dREG analysis identifies evidence of active differential transcription based on genotype in the region of 5 out of 6 GWAS-identified SNPs that we have investigated so far.

P238

BIALLELIC TP53 GENE MUTATIONS DUE TO COPY-NEUTRAL LOSS OF HETEROZYGOSITY AND MONOALLELIC MUTATIONS IN ABSENCE OF 17P DELETION OCCUR IN CLL WITH COMPARABLE FREQUENCY

K. Plevova[1,2,*], J. Malcikova[1,2], S. Pavlova[1,2], J. Kotaskova[1,2], L. Poppova[1,2], J. Smardova[3], E. Diviskova[2], K. Durechova[2], A. Oltova[2], Y. Brychtova[2], A. Panovska[2], M. Doubek[1,2], S. Pospisilova[1,2]

[1]Central European Institute of Technology, Masaryk University, [2]Department of Internal Medicine - Hematology and Oncology, [3]Department of Pathology, University Hospital Brno, Brno, Czech Republic

Background: *TP53* gene defects represent an adverse prognostic marker in chronic lymphocytic leukemia (CLL). In the majority of affected cases, *TP53* is inactivated on both alleles due to the concurrent mutation and 17p deletion [del(17p)]. However, in about one third of cases, only *TP53* mutation (*TP53*mut) without deletion is detected. It was reported that in some of these patients, copy-neutral loss of heterozygosity (cn-LOH), also leading to biallelic *TP53* defect, might be present; however the frequency of such event has not been thoroughly investigated.
Aims: We aimed to perform a detailed analysis of the second *TP53* allele status in cases with a *TP53* mutation in the absence of del(17p), and to assess genomic makeup and clinical outcome in these patients.
Methods: We searched for patients with *TP53*mut in absence of del(17p) within the cohort of 200 CLL patients positive for *TP53*mut as determined using FASAY (Functional Analysis of Separated Alleles in Yeast) coupled to direct sequencing;

17p13 deletions were assessed by FISH (MetaSystems). More than a half of the cohort (57%) was also tested using ultra-deep NGS for *TP53* exons 2-11. Genome-wide analysis was performed on CytoScanHD arrays (Affymetrix) and correlated to conventional cytogenetics (CpG/IL-2 stimulation).
Results: Out of the cohort positive for *TP53*mut, 72/200 patients (36%) harbored single dominant *TP53*mut without del(17p). We selected 43 of these cases with variant allele frequency (VAF) >10% for CytoScan analysis to explore the potential presence of 17p cn-LOH. In 42% (18/43) of the cases, cn-LOH in 17p locus was detected in a proportion of CLL clone correspondingly to the *TP53* VAF (median *TP53* VAF 59.4%, range 12.9–99.9%). In 3/43 cases, heterozygous deletion previously undetected by FISH was newly revealed. Thus, the truly monoallelic mutations were confirmed in 51% (22/43) of the cases, where no cytogenetic abnormality in 17p locus was observed (median *TP53* VAF 43.5%, range 10.5–51.3%). Applying a VAF cut-off of 55% indicating fully expanded heterozygous mutation (taking into account the potential unequal representation of forward and reverse strands in NGS data), 7/29 (24%) cases below the cut-off still harbored 17p cn-LOH. These results show that it is not possible to use an arbitrary VAF cut-off (>50%) to identify biallelic mutations due to cn-LOH. When we compared genomic complexity of leukemic clones with monoallelic *vs* biallelic *TP53*mut as determined by the CytoScan array, the latter group exhibited significantly more genomic abnormalities (p=0.0388) and also preference for different recurrent chromosomal abnormalities (p<0.0001; 17p locus excluded from this analysis). However, there was no significant difference in overall survival between the groups (p=0.5856).
Summary/Conclusions: cn-LOH in 17p locus is present in approximately half of the patients with single dominant *TP53*mut and results in biallelic *TP53* gene inactivation despite the absence of del(17p); truly monoallelic *TP53* gene mutations with an intact second allele occur in CLL with comparable frequency. Although 17p cn-LOH is associated with increased genomic instability, it does not have worse impact on clinical outcome than truly monoallelic *TP53*mut.
Supported by the projects AZV-MZCR 15-31834A, 15-30015A, 15-29793A, the EU Horizon2020 project No. 692298, and MEYS CEITEC2020 LQ1601.

P239

INTERGRATED OLIGO/SNP ARRAY- AND NEXT GENERATION SEQUENCING BASED ANALYSIS IS REQUIRED TO DETERMINE TP53/17P STATUS IN CLL PATIENTS

M. Stevens-Kroef[1,*], A. Eijkelenboom[1], L. Kroeze[1], D. Olde Weghuis[1], P. Groenen[1]
[1]Radboud university medical center, Nijmegen, Netherlands

Background: B-cell chronic lymphocytic leukemia (CLL) exhibits a highly heterogeneous clinical course, with overall survival rates varying from several months to decades. Mutation status of the *IGHV* genes and specific genomic abnormalities, such as deletion of 11q22 en loss of the 13q14 region provide prognostic information. However, more importantly deletion of 17p and/or the presence of a *TP53* mutation, which are both associated with a poor prognosis identify CLL patients with the highest risk profile. Recently clinical trials with tyrosine kinase inhibitors such as ibrutinib and idelalisib have demonstrated good responses in CLL patients with 17p deletion and/or *TP53* mutations. In many studies interphase fluorescence *in situ* hybridization (FISH) for the detection of 17p deletions and Sanger sequencing of exons 4-10 of the *TP53* gene are applied, resulting in incorrect classification of patients belonging to the highest risk group, due to absence of information regarding the heterozygosity status and low sensitivity of the sequencing technology.
Aims: We have applied an integrated approach to determine the *TP53*/17p status in CLL patients using oligo/SNP-based array which allows a genome-wide detection of copy number alterations (CNAs), down to 100 kb in size, and regions of copy neutral loss of heterozygosity (CNLOH). In addition the presence of *TP53* mutations was evaluated with high sensitivity using next generation sequencing approaches.
Methods: We have studied bone marrow or peripheral blood samples of 179 CLL patients that were referred to our diagnostic genetic center for analysis of 17p deletion, 17p CNLOH and the *TP53* mutation. To determine the *TP53* mutation status (exons 2-11) sequence analysis was performed by next generation sequencing with a sensitivity up to 1% mutant allele frequency. For the determination of the 17p status we have used a high resolution CytoScan HD Array (Affymetrix) platform which allows the detection of copy number alterations (*e.g.* deletions) as well as CNLOH.
Results: Twenty-one of the 179 CLL patients exhibited a loss or CNLOH of the short arm of chromosome 17 as demonstrated by oligo/SNP-based array. Eight of these cases had a CNLOH of 17p and would not have been observed in case interphase FISH had been performed. In addition, by applying *TP53* mutation analysis 26 patients were identified in whom the *TP53* gene was inactivated. In six of these cases the mutant allele frequency was below 20% and would have escaped detection by Sanger sequencing. Therefore ten of the 26 (38%) patients with *TP53*/17p aberration would not have been indentified in case diagnostics was based on FISH and Sanger sequencing. To evaluate whether both alleles of the *TP53* gene were inactivated the data of the 17p deletion, 17p heterozygosity status and *TP53* mutation status were integrated. It appeared that in all 13 patients with a 17p deletion the other *TP53* allele was inactivated due to a mutation. In all patients demonstrating CNLOH of the chromosome 17p region the *TP53* gene was also inactivated due to a mutation. In the other 5 patients with a *TP53* mutation no loss or CNLOH of 17p was demonstrated. However, two of these patients harbored two different *TP53* mutations, suggestive for inactivation of both *TP53* alleles.
Summary/Conclusions: By applying an integrated approach for determination of the *TP53*/17p status a substantial higher amount of patients were categorized to the highest risk group of CLL patients with *TP53*/17p abnormalities.

P240

CYTOGENETIC CLONAL EVOLUTION OCCURS AT THE TIME OF DISEASE PROGRESSION DURING IBRUTINIB THERAPY IN PATIENTS WITH RELAPSED/REFRACTORY CLL

P. Thompson[1,*], J. Burger[1], M. Keating[1], S. O'Brien[2], P. Jain[1], A. Ferrajoli[1], N. Jain[1], E. Zeev[1], W. Wierda[1]
[1]Department of Leukemia, MD Anderson Cancer Center, Houston, [2]Chao Comprehensive Cancer Center, University of California, Irvine, United States

Background: Patients (pts) with del(17p) and complex karyotype (CKT) have increased likelihood of disease progression during ibrutinib therapy for CLL. Cytogenetic clonal evolution (CCE) is frequent at the time of disease progression following chemotherapy, particularly emergence of del(17p). Additionally, pts with del(17p) or *TP53* mutations frequently develop additional copy number alterations (CNAs) following chemotherapy.
Aims: To determine whether CCE occurs during ibrutinib therapy and at disease progression.
Methods: We analyzed 336 pts treated on investigational studies with ibrutinib or ibrutinib plus rituximab for CLL. In pts who progressed, we analyzed FISH and cytogenetic results pre-treatment and at progression, to identify CCE. Additionally, we identified a sub-group of 97 relapsed/refractory pts who had serial FISH analysis performed in bone marrow ≥1 year apart, to determine whether there were significant changes in sub-clonal composition of CNAs detected by FISH during treatment in the absence of disease progression.
Results: In total, 37 of 336 pts (11%) progressed during ibrutinib-based therapy. Of these pts, 15 had FISH analysis both pre-treatment and at progression: pre-treatment, 10 had del(17p), 1 had del(11q) and 4 had isolated del(13q). All 4 of the pts with isolated del(13q) pre-treatment had new subclonal FISH abnormalities detected at progression: two pts had del(17p), 1 had del(11q); a 4th pt developed two additional copies of all targeted regions at progression, suggestive of tetraploidy. The pt with del(11q) pre-treatment who progressed developed Richter Transformation (RT) in the bone marrow at progression, without either del(11q) or del(17p) identified by FISH, suggesting that the RT arose from a common ancestral clone without del(11q) or was clonally unrelated. Median FISH%del(17p) pre-treatment in those with del(17p) was 72%; only 1 pt had <50% del(17p) pre-treatment. All these pts had persistence of del(17p), at progression, without significant changes in allelic frequency. Two pts with del(17p) pre-treatment had additional abnormalities detected by FISH at progression: sub-clonal biallelic del(13q) was seen in two pts, one of whom also developed tetrasomy 12. In the absence of disease progression, the only CCE detected was emergence of small subclones with biallelic del(13q) in two patients who initially had monoallelic del(13q). Notably, in responding pts, there was no expansion of high-risk sub-clones. Conventional karyotyping was performed in 10/37 patients who progressed both pre-treatment and at progression. In 4 pts, CCE was identified at progression, including 17 new abnormalities in one pt. All 4 pts had complex karyotype and del(17p) by FISH pre-treatment and 3 of 4 had evidence of multiple, related, complex sub-clones pre-treatment. Figure 1 shows inferred clonal evolution pattern for one pt.

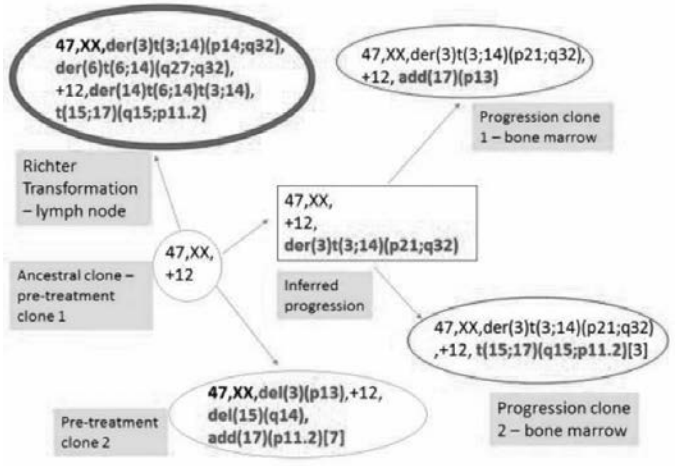

Figure 1.

Summary/Conclusions: Emergence of high-risk clones containing del(17p) and or del(11q) may be seen at disease progression in ibrutinib-treated patients. Analogous to allelic expansion of *TP53* mutations after chemotherapy, we hypothesize that small del(17p) or del(11q) subclones were present prior to therapy in these pts, below the sensitivity of existing FISH techniques and expanded under the selective pressure of ibrutinib treatment. Development of a more sensitive technique to identify small sub-clones with del(11q) or del(17p) may therefore be important. Additionally, complex CCE occurred at progression in several cases, indicating genomic instability and potentially contributing to therapeutic failure.

P241

LANDSCAPE OF SOMATIC MUTATIONS AND THEIR IMPACT ON RESPONSE AND OUTCOMES FROM LENALIDOMIDE-BASED THERAPIES IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

B. Hu[1,*], F. Wang[2], Y. Yuanqing[3], E. Kim[4], K. Patel[5], P. Strati[1], C. Gumbs[2], L. Little[2], S. Tippen[2], X. Song[2], J. Zhang[2], N. Jain[4], P. Thompson[4], K.-A. Do[3], M. Keating[4], J. Burger[4], A. Ferrajoli[4], W. Wierda[4], A. Futreal[2], K. Takahashi[4]
[1]Cancer Medicine, [2]Genomic Medicine, [3]Biostatistics, [4]Leukemia, [5]Hematopathology, MD Anderson Cancer Center, Houston, Texas, United States

Background: Lenalidomide, either as a single agent or in combination with anti-CD20 monoclonal antibody, is clinically active in CLL and offers durable response in some pts. Predictive and prognostic impact of somatic mutations are not well known in pts with CLL who have received lenalidomide-based therapies.
Aims: Investigate the overall landscape of CLL gene mutations in both previously untreated and relapsed/refractory (R/R) pts. Determine associations between CLL gene mutations and clinical characteristics. Establish predictive and prognostic impact of CLL mutations in the context of lenalidomide-based therapies.
Methods: In the 288 pts with CLL who were treated in one of the lenalidomide-based clinical trials at our institution, we performed targeted gene capture exome sequencing of 295 genes that have been recurrently mutated in hematologic malignancies on pre-treatment samples. This sequencing platform also included more than 1000 cyto SNP position that allowed copy number variation (CNV) estimation. We used Mutect and Pindel algorithms to call high-confidence somatic mutations and used in-house algorithm to detect copy number variations (CNVs) in CLL samples.

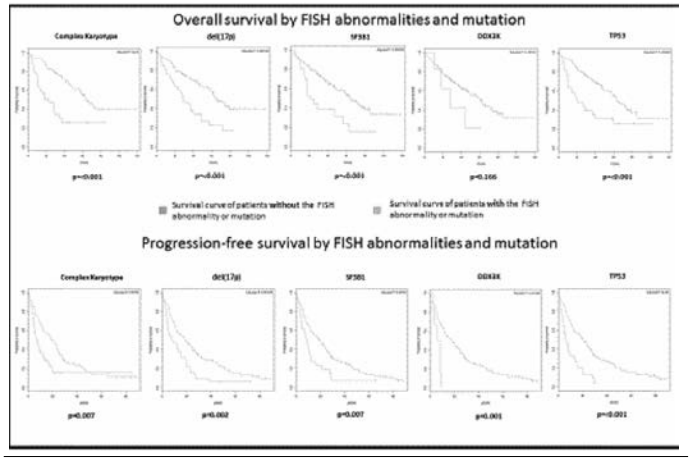

Figure 1.

Results: Among the 288 CLL pts treated with lenalidomide, 102 (35%) were previously untreated and 186 had R/R CLL. Ninety two patients (32%) received lenalidomide as a single agent and 196 patients (68%) received in combination with rituximab or ofatumumab. In total, we detected 470 high-confidence somatic mutations in 61 genes in 281 pts (76%). In addition to the well-known arm-level chromosomal abnormalities like del(13q), del(11q), tri(12), and del(17p), we also detected amp(2p), del(6q), del(8p), amp(8q) and tri(19). The most frequently mutated gene was SF3B1 (15%), followed by NOTCH1 (14%) and TP53 (14%) with 13 gene mutations occurring ≥3%. The number of mutations was similar between untreated and R/R pts (median number of mutations 1 [IQR: 0-2] *vs* 1 [IQR: 1-2], P=0.44) with increased enrichment of complex cytogenetics, TP53 mutation and del(17p) in the R/R cohort (p=0.006, p=0.014 and p=0.031, respectively). The pts with unmutated IGHV status had higher number of mutations compared to mutated IGHV (median 1 [IQR: 1-2] *vs* 1[IQR: 0-2], P=0.002) with MYD88 mutation and del(13q) being significantly enriched in IGHV mutated pts (p=0.005 and p=0.028, respectively) while NOTCH1 and XPO1 mutations were significantly enriched in IGHV unmutated patients (p=0.035 and p=0.047, respectively). Pairwise association showed statistically significant co-occurrence between tri(12) and mutations in KRAS/BCOR (both q<0.05), NOTCH1 mutation and ZMYM3 (q<0.01)/SPEN (q<0.05) mutations, and TP53 mutation and del(17p) (q <0.01)/complex karyotypes (q <0.05). When correlating with clinical response to lenalidomide, worse overall response (OR) in the untreated group was associated with del(17p) (p=0.019) and KRAS mutation (p=0.05), whereas mutation in SF3B1 (p=0.025), MGA (p=0.035), DDX3X (p=0.002), TP53 (p<0.001), complex karyotype (p=0.035) and del(17p) (p=0.031) were associated with worse OR in R/R group. In the untreated group, del(17p) and TP53 were associated with worse progression-free (PFS)(p=0.002 and 0.003, respectively). In R/R cohort, complex karyotype, del(17p) and mutations in SF3B1 and TP53 were associated with worse OS and PFS while DDX3X was associated with worse PFS but not OS (refer to provided Figure 1). In one of the multivariate models, SF3B1 (P=0.005) mutation and having TP53 or del(17p) (p=0.02) were prognostic for survival in R/R cohort.
Summary/Conclusions: Tumor mutational heterogeneity in CLL is due to intrinsic tumor biology and selective drivers from previous treatments, which can then affect response and survival in lenalidomide-based therapies.

P242

HIGH THROUGHPUT IMMUNOPROFILING OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS ASSIGNED TO STEREOTYPED SUBSET #4: NOVEL INSIGHTS INTO THE DEPTH, DIVERSITY AND TEMPORAL DYNAMICS OF CLONAL EVOLUTION

K. Gemenetzi[1], E. Stalika[1], A. Vardi[1], F. E. Psomopoulos[1], E. Minga[1], A. Anagnostopoulos[2], K. Stamatopoulos[1,3], A. Hadzidimitriou[1], L. A. Sutton[3,4,*]
[1]Institute of Applied Biosciences, CERTH, [2]Hematology Department and HCT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece, [3]Department Of Immunology, Genetics & Pathology, Uppsala University, Uppsala, [4]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden

Background: Chronic lymphocytic leukemia (CLL) clones assigned to stereotyped subset #4 are characterized clinically by a young age at diagnosis and an indolent disease course, and molecularly by B-cell receptor immunoglobulins (BcR IGs) that exhibit distinctive immunogenetic features. More specifically, they are IgG-switched, composed of heavy and light chains encoded by the IGHV4-34 and IGKV2-30 genes, respectively, and their heavy chain complementarity determining region 3 (VH CDR3s) is long and enriched in positively charged residues, reminiscent of pathogenic anti-DNA antibodies. In addition, both the VH and VK domains of subset #4 demonstrate a high impact of somatic hypermutation (SHM), highly indicative of an (auto)antigen selection.
Aims: To obtain comprehensive insights into the ontogeny and evolution of CLL subset #4 using next-generation sequencing (NGS) for in-depth immunoprofiling of the clonotypic BcR IG genes, particularly focusing on analyzing intraclonal diversification (ID) within the IG gene sequences.
Methods: Peripheral blood samples were collected at multiple time-points over a 10-year period from 6 CLL subset #4 patients. The clonotypic IGHV-IGHD-IGHJ and IGKV-IGKJ rearrangements were amplified by PCR using cDNA and sequenced on the MiSeq (Illumina). Our experimental design involved paired-end sequencing, thus allowing sequencing of the CDR3 twice/read, so as to increase the accuracy of results. To maintain stringency, raw NGS reads were subjected to purpose-built, bioinformatics algorithms, which performed: (i) length and quality filtering of raw reads; (ii) merging of filtered-in paired reads via local alignment; and, (iii) length and quality filtering of stitched sequences. No base calls of Q-score<30 were allowed in the 75 nucleotide stretch preceding the GXG motif, further increasing CDR3 sequencing reliability. Data was then analyzed using the IMGT/HighV-QUEST database and clonotype computation was performed using an in-house bioinformatics pipeline.
Results: Overall, 48 samples were analyzed, producing 12,386,554 and 4,506,464 total reads for heavy and light chain, respectively. In addition to filtering out poor quality, incomplete, out-of-frame and unproductive rearrangements, specific parameters were applied regarding V-region identity (>85%), usage of subset #4-specific V- and J-genes, CDR3 length and landmark residues. Applying these strict criteria resulted in 84.1% (median 401,133 reads/sample) and 90.3% (median 141,549.5 reads/sample) of the total sequences obtained for the heavy and light chain, respectively, passing filters. Clonotype computation was solely based on the filtered-in sequences and revealed a median of 1332.5 clonotypes/sample (range: 879-3432) for the heavy chains while a median of 202.5 clonotypes/sample (range: 125-395) was evidenced for the light chains. Overall, our longitudinal analysis revealed: (i) a hierarchical pattern of subclonal evolution showing which SHMs were negatively or positively selected; (ii) distinct clusters of subcloned sequences which at later time-points had often disappeared and hence been selected against; and, (iii) that despite the high intensity of ID, certain residues remained essentially unaltered alluding to strong functional constraints.
Summary/Conclusions: Detailed molecular immunoprofiling by NGS afforded the possibility to gain novel insights into the pathogenesis of CLL subset #4, thus providing conclusive evidence that these patients continue to acquire SHMs within their IG genes; an observation best explained by a clear role for antigen selection in clonal evolution.

P243

FAILED HYDROXYMETHYLATION CONTRIBUTES TO A CHRONIC LYMPHOCYTIC LEUKEMIA SPECIFIC EPIGENOTYPE

K. Szarc Vel Szic[1,*], K. Loose[1], G. Andrieux[2], A. Heumüller[1], N. Glaser[3], S. Hild[1], J. Duyster[1], H. Busch[2], M. Börries[2], R. Claus[1]
[1]Division Hematology, Oncology and Stem Cell Transplantation, University Freiburg Medical Center, [2]Institute of Molecular Medicine and Cell Research, University Freiburg, [3]Center for Chronic Immunodeficiency, University Freiburg Medical Center, Freiburg, Germany

Background: During normal hematopoiesis, a coordinated epigenetic and transcriptional programming is necessary to achieve lineage development. B cell differentiation is predominantly related to loss of DNA methylation at the enhancers and promoters of B cell-specific genes; *e.g.* transcription factors (TFs). In chronic lymphocytic leukemia (CLL), failure of proper epigenetic programming contributes to deregulation of B cell transcriptional programs and results in CLL phenotypes with highly variable outcomes. The mechanisms leading to failed epigenetic programming and to establishment of a CLL epigenome are not well understood. Genomic sites of failed epigenetic programming coincide with binding sites of key B cell TFs. Active DNA demethylation through TET-dioxygenase mediated conversion of 5-methylcytosine (5mC) to 5-hydroxymethylcytosine (5hmC) and subsequent products is one of the mechanisms involved in physiological epigenetic B cell programming, and deregulation of this process could contribute to establishment of the CLL epigenome.
Aims: Here, we investigated the role of TET2-mediated DNA demethylation through differential 5hmC acquisition in healthy and in CLL B cells. We further studied mechanisms and TFs involved in regulation of 5hmC conversion during CLL pathogenesis.
Methods: Clonal B cell specimens from 122 CLL patients were subjected to DNA methylation profiling using Illumina 450k arrays. 17 CLL and 4 healthy B cell samples (CD19+) were used for DNA methylation profiling using Illumina Epic arrays and for hydroxymethylated DNA immunoprecipitation (hMeDIP) using a monoclonal 5hmC mouse antibody and the NEBNext Ultra DNA Library Prep Kit for analysis on a Illumina HiSeq2000 sequencer. Global 5hmC levels were quantified by dot blots. TET2, and EBF1 mRNA and protein expression was evaluated by qPCR and Western Blot, respectively.
Results: By dot blot, we found decreased 5hmC levels in CLL as compared to CD19+ B lymphocytes. 5hmC was further reduced in IGHV unmutated compared to IGHV mutated CLL patients. To identify distinct regions with gain or loss of 5hmC, we performed genome-wide 5hmC profiling by hMeDIP. We confirmed a significantly lower number of hydroxymethylated peaks in CLL (137114) compared to HBC (249421) which remained stable when separating to good (133234, $p<0.0102$) or bad prognosis CLL (140441; $p<0.0161$) patients (defined by the IGHV mutation status, Rai/Binet stages, CD38 positivity, del(11q) and del(17p)). Differential binding analysis (DBA) revealed 5988 significantly differentially hydroxymethylated reads between CLL and HBC samples (FDR<0.05). Pathway analysis showed that regions which lost hydroxymethylation in CLL were involved in B cell receptor (BCR), Class I PI3K, CXCR-4, c-Mec and IL3 signaling. To further identify mechanisms that are involved in failed hypomethylation and 5hmC loss in CLL, we aimed at profiling sequence characteristics at the respective genomic sites. In our genome-wide DNA methylation data set, we confirmed highly significant enrichment of the EBF1 motif at the respective sites in 122 CLL patients. EBF1 mRNA and protein expression was significantly reduced in the majority of 17 CLL samples compared to HBC. TET2, a potential interaction partner of EBF1, was upregulated in CLL samples on RNA level and expressed to different degree on protein level.
Summary/Conclusions: Here, we demonstrate that 5hmC loss in CLL contributes to a disease specific epigenotype as described earlier. First evidences indicate that alterations of an interaction between the EBF1 and TET2 are mechanistically involved in insufficient hydroxymethylation and consequently failed DNA hypomethylation.

Background: Subsets of CLL patients carrying stereotyped B cell receptors (BcRs) display distinct biological and clinical features; however, the DNA methylation landscape for these patients remains largely unexplored.
Aims: To investigate the DNA methylation profiles in three major stereotyped subsets.
Methods: By applying high-resolution 450K methylation arrays, we studied the clinically aggressive subsets #1 (Clan I genes/IGKV(D)1-39, IGHV unmutated, n=37) and #2 (IGHV3-21/IGLV3-21, mixed IGHV mutation status, n=35) and the indolent subset #4 (IGHV4-34/IGKV2-30, IGHV mutated, n=28). In addition, a series of sorted normal subpopulations spanning different stages of B-cell differentiation (*e.g.* naïve, centrocytes, centroblasts, memory) were analyzed.
Results: Unsupervised principal component analysis demonstrated that the investigated subsets formed distinct subgroups and these findings were corroborated by hierarchical clustering analysis. We next explored if and how these subsets match to the recently proposed epigenetic classification of CLL, which subgroups patients into three categories, defined as i) poor-prognostic, naïve like CLL (n-CLL), ii) good-prognostic, memory like CLL (m-CLL), broadly corresponding to IGHV unmutated and mutated CLL, respectively; and iii) a third intermediate CLL subgroup (i-CLL), which have borderline mutated IGHV genes and an intermediate outcome. For this purpose, we utilized the same methylation arrays to study a cohort of CLL cases that did not express stereotyped BcRs ('non-subset', n=325). Comparison of subset *vs* non-subset CLL, grouped based on their epigenetic classification, revealed that subset #1 clustered with n-CLL, subset #4 with m-CLL, while subset #2 clustered separately with i-CLL. We have recently shown that the number of epigenetic changes that a tumor acquired, compared to its cellular origin (*i.e.* 'epigenetic burden'), may be a powerful predictor of clinical aggressiveness (Queiros *et al.*, Cancer Cell 2017). Following this approach in CLL, when comparing specific subsets *vs* their non-subset cases matched by epigenetic subgroup, we noted a significant difference in the epigenetic burden amongst the various groupings; more specifically, in subset #1 *vs* n-CLL (72K *vs* 67K, $p<0.05$) and in subset #2 *vs* i-CLL (76K *vs* 68K, $p=0.001$), while no difference was observed between subset #4 *vs* m-CLL (83K *vs* 82K, p=not significant). This implies that subsets #1 and #2 have a higher epigenetic burden than n-CLL, which is in line with the more aggressive disease seen in these two subsets compared to the broader category of n-CLL patients. Focusing on subset #2, we observed that almost all cases clustered separately from i-CLL in supervised clustering analysis, providing further support that subset #2 forms a distinct subgroup of i-CLL. Subset #2 cases frequently carry del(11q) and harbor *SF3B1* mutations, however, neither the IGHV mutation status nor the presence of del(11q) or *SF3B1* mutations had any impact on the epigenetic burden within subset #2.
Summary/Conclusions: Stereotyped CLL subsets differed significantly in their methylation profiles. That said, subset #1 and #4 clustered at large with n-CLL and m-CLL categories, respectively, implying common cellular origin. In contrast, subset #2 emerged as the first defined member of the i-CLL group, which in turn alludes to a distinct cellular origin for subset #2 and i-CLL patients. Both subsets #1 and #2 displayed a higher epigenetic burden compared to n-CLL and i-CLL, respectively, which is likely reflected in the very poor outcome associated with these two subsets.

Chronic lymphocytic leukemia and related disorders - Clinical

P245

ADDING OBINUTUZUMAB TO IBRUTINIB ENHANCES DEPLETION OF CLL CELLS IN PERIPHERAL BLOOD AND BONE MARROW AFTER 1 & 6 MONTHS COMBINED THERAPY INITIAL RESULTS FROM THE BLOODWISE TAP ICICLLE EXTENSION STUDY

A. Rawstron[1,*], T. Munir[2], S. Muñoz-Vicente[3], K. Brock[3], F. Yates[3], R. Bishop[3], S. Dalal[3], R. de Tute[2], O. Sheehy[4], A. Pettitt[5], C.P. Fox[6], C. Fegan[7], S. Devereux[8], D. MacDonald[9], A. Bloor[10], P. Hillmen[2]
[1]HMDS, St. James's Institute of Oncology, [2]St. James's Institute of Oncology, Leeds, [3]Cancer Research UK Clinical Trials Unit, University of Birmingham, Birmingham, [4]Belfast City Hospital HSC Trust, Belfast, [5]Royal Liverpool and Broadgreen University Hospitals NHS Trust, Liverpool, [6]Nottingham University Hospitals NHS Trust, Nottingham, [7]University Hospital of Wales, Cardiff, [8]Kings College Hospital NHS Foundation Trust, [9]Hammersmith Hospital, Imperial College Healthcare NHS Foundation Trust, London, [10]The Christie NHS Foundation Trust, Manchester, United Kingdom

Background: A major aim of CLL treatment is to eradicate detectable minimal residual disease (MRD). Ibrutinib is an effective treatment for CLL that results in immediate lymphocytosis persisting in most patients for several months. Obinutuzumab is a second generation anti-CD20 monoclonal antibody which can effect rapid resolution of lymphocytosis and eradication of MRD in some CLL patients. The IcICLLe Extension Study expands on the IcICLLe trial (ISRCTN12695354) to examine the efficacy and safety of the combination treatment of obinutuzumab and ibrutinib.
Aims: The IcICLLe trial was a single-arm, multicentre feasibility study that recruited 40 participants with CLL requiring treatment, 20 treatment-naïve (TN) and 20 relapsed/refractory (RR), to receive continuous ibrutinib therapy until confirmed MRD negative remission (<0.01% residual disease) or disease progression. The IcICLLe Extension Study adds 40 RR participants with CLL requiring treatment to receive continuous ibrutinib therapy from day 0 and 6 cycles of obinutuzumab from day 1. 30 participants have no prior ibrutinib treatment (ibrutinib-naïve), and 10 are pre-treated with ≥12 months of ibrutinib on IcICLLe. The primary outcome for the IcICLLe Extension Study is the proportion of patients achieving MRD-negative remission by IWCLL criteria (depletion of CLL below 0.01% in the peripheral blood and bone marrow) at or before 9 month assessment.
Methods: Adverse Events are collected from registration until 30 days after end of treatment and reported using the Common Terminology Criteria for Adverse Events v4.0. MRD was assessed by multiparameter flow cytometry according to ERIC 2016 guidelines with a detection limit ≤0.004%.
Results: 31 participants (22 ibrutinib-naïve and 9 pre-treated) are evaluable for response assessment after 1 month of combination treatment. There have been no reports of tumour lysis syndrome within the first month of combination treatment. There were 2 separate reports of grade 2 infusion related reactions, both on day 1 of obinutuzumab. In the 22 ibrutinib-naïve cases peripheral blood (PB) CLL counts remained at or below baseline levels in 17/22 cases from week 1 onwards. After 1 month of combination therapy the PB CLL count was a median 31% of baseline levels (range <1%>174%) compared to median 215% (range 29%>3570%) for RR patients on ibrutinib monotherapy. Percentage CLL cells in the bone marrow (BM) aspirate after 1 month of combination therapy reduced from a median 83% (range 23-94%) to a median 47% (range 5-85%, P=0.003, Wilcoxon matched-pairs signed ranks). For RR patients on ibrutinib monotherapy there was no change in BM at 1 month: baseline median 85% (range 11-96%) compared to median 86% (range 50-98%, P=0.96). Changes in BM aspirate CLL percentage were confirmed by morphological assessment of a trephine biopsy with all evaluable patients receiving obinutuzumab showing improvements in the cellularity and/or extent of infiltration. BM assessment at 1 month was not mandated for the 9 pre-treated patients but all showed decreased PB CLL counts with 4/9 achieving <0.01% residual disease within 3 months of starting obinutuzumab. 13 patients have completed 6 months of obinutuzumab treatment with marrow assessment at 9 months showing a further ≥1 log depletion in CLL percentage in 9/13 patients with 4/6 pre-treated patients achieving <0.01% residual disease.
Summary/Conclusions: The data indicate that for RR patients, the addition of obinutuzumab to ibrutinib results in a substantial improvement over ibrutinib monotherapy in the depletion of CLL cells from peripheral blood and bone marrow after 1 month of combination therapy, and continued improvement after 6 months combination therapy, with MRD-negative BM responses for patients who have had >1yr prior ibrutinib monotherapy. Residual disease levels in the BM after the 6 months of combination treatment will be available for 25 participants by June-2017.

P246

CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS EXPRESSING THE LIGHT CHAIN IGLV3-21 HAVE A POOR PROGNOSIS INDEPENDENTLY OF HEAVY CHAIN IGHV3-21 OR THE IGHV MUTATIONAL STATUS

B. Stamatopoulos[1,*], T. Smith[2], D. Sims[2], A. Heger[2], H. Dreau[3], A. Schuh[4]
[1]Laboratory of Clinical Cell Therapy, J. Bordet Institute, University of Brussels, Brussels, Belgium, [2]Computational Genomics Analysis and Training Programme, MRC Weatherall Institute of Molecular Medicine, University of Oxford, John Radcliffe Hospital, [3]Molecular Diagnostic Centre, Oxford University Hospitals, [4]Department of Oncology, University of Oxford, Oxford, United Kingdom

Background: The immunoglobulin heavy-chain gene (IgHV) mutational status is currently considered the gold standard of prognostication in Chronic Lymphocytic Leukemia (CLL): unmutated (UM) immunoglobulin heavy chain region (IgHV) is associated with poor prognosis while patients with mutated IgHV (M) have more indolent disease. An exception are patients with IgHV3-21/IgLV3-21 who have poor prognosis irrespectively of the IgHV mutational status. Interestingly, IgHV3-21 is co-expressed with IgLV3-21 in the majority of cases.
Aims: Here we aimed to study the impact of the light chain IgLV3-21 on CLL prognosis. This light chain has never been characterized independently of the heavy chain IgHV3-21.
Methods: Based on 405 CLL patients from 3 independent cohorts (A. an initial cohort of 32 patients with aggressive CLL, and 2 cohorts of CLL patients where samples were obtained at diagnosis (B: n=270 and C: n=103), we analyzed the impact of the presence of IgLV3-21 on treatment-free (TFS) and overall (OS) survival. IgLV3-21 positivity was determined by real-time PCR and confirmed by Sanger sequencing.
Results: Among the 32 patients with aggressive CLL, we found that 9 (28%) patients who had an IgLV3-21 rearrangement, but only 1 patient carried the heavy chain IgHV3-21: IgLV3-21 patients had a median TFS of 17 months compared to 44 months in patients with another light chain (P=0.0270). Similarly, IgLV3-21 patients had a shorter median OS (88 months *vs* >192 months, P=0.0287). We verified these results in 2 independent cohort obtained at diagnosis. In cohort B (n=270), 30 (11%) expressed an IgLV3-21 light chain and 10 (4%) an IgHV3-21 (of which 8/10 also carried the light chain IgLV3-21 rearrangement). Patients with IgLV3-21 had a median TFS/OS of 29/183 months compared to patients without IgLV3-21 who had a median TFS/OS of 88/292 months (P=0.0003/P=0.0142). In cohort C (n=103), 9 (9%) expressed an IgLV3-21 light chain but only 1 (1%) had a heavy chain IgHV3-21. In this cohort, IgLV3-21 patients had a median TFS of 21 months not statistically different from IgHV UM patients (28 months) while IgHV M patients had a median TFS of 93 months (P<0.0001). We then pooled the 3 populations (n=405) in order to increase the under-represented subgroups and analyzed the association of the IgLV3-21 with the IgHV mutational status: patients with either IgHV3-21 or IgLV3-21 (with a M or UM IgHV) displayed a prognosis similar to UM patients: median TFS was 129, 48, 36, 24, 23 months for M, IgLV3-21/M (P=0.0005), UM (P<0.0001), IgLV3-21/UM (P<0.0001) and IgHV3-21 (P<0.0001) patients, respectively (Figure 1A). Similar results were observed for OS with a median OS of 292, 88, 174, 90 and 183 months M, IgLV3-21/M (P<0.0001), UM (P<0.0001), IgLV3-21/UM (P<0.0001) and IgHV3-21 (P=0.0021) patients, respectively (Figure 1B). If all IgLV3-21 (n=48) were considered independently of their heavy chain, IgLV3-21 median TFS (24 months) was similar to UM patients (36 months, P=0.5824) and statistically different from M patients (129 months – P<0.0001, Figure 1C). Similar results were observed for OS (Figure 1D).

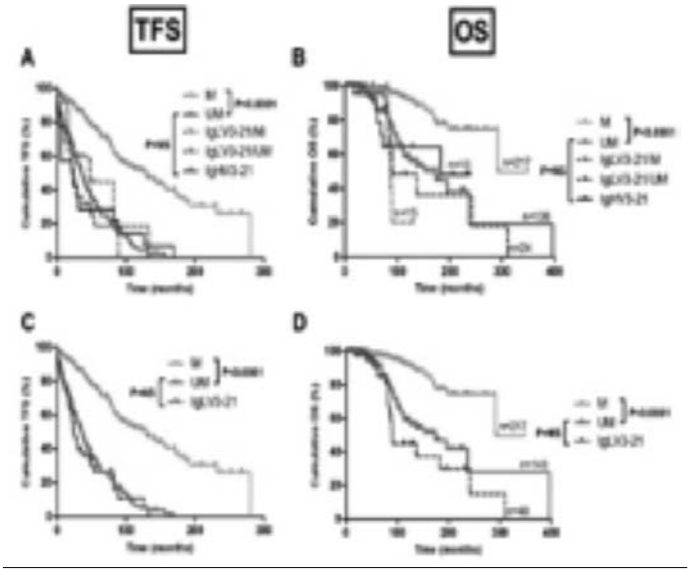

Figure 1.

Summary/Conclusions: Our results highlight for the first time the independent prognostic significance of the light chain IgLV3-21 in CLL: the presence of an IgLV3-21 light chain confers a poor prognosis similar to UM patient irrespectively of concurrent expression of IgHV3-21 heavy chain or IgHV mutational status.

P247

DURABILITY OF RESPONSES ON CONTINUOUS THERAPY AND FOLLOWING DRUG CESSATION IN DEEP RESPONDERS WITH VENETOCLAX AND RITUXIMAB

M.A. Anderson[1,*], D.M. Brander[2], S. Ma[3], J.F. Seymour[4], M.Y. Choi[5], T.J. Kipps[5], L. Zhou[6], K. Balbarin[6], B. Prine[6], M. Verdugo[6], S.Y. Kim[6], L.L. Lash[6], A.W. Roberts[1]

[1]Royal Melbourne Hospital and Walter and Eliza Hall Institute of Medical Research, Cancer and Hematology Division, Melbourne, Australia, [2]Duke University Medical Center, Durham, [3]Northwestern University, Chicago, United States, [4]Peter MacCallum Cancer Centre, , Melbourne, Australia, [5]University of California San Diego, San Diego, [6]AbbVie, Inc., North Chicago, United States

Background: Venetoclax is a potent BCL-2 inhibitor that is approved as monotherapy for certain patients with relapsed or refractory chronic lymphocytic leukemia (CLL) in the United States, the European Union, and other countries.
Aims: Venetoclax combined with rituximab is being assessed in an ongoing Phase 1b study.
Methods: Minimal residual disease (MRD) was assessed in bone marrow using ≥4-color flow cytometry (minimum sensitivity: 0.01%). Patients who achieved complete remission (CR) or MRD-negativity could stop venetoclax and remain on study. Patients who manifested progressive disease while off therapy could re-initiate venetoclax and rituximab.
Results: Forty-nine patients, with a median of 2 (range: 1–5) prior regimens, were enrolled. As of July 2016, the overall response rate was 86%, the CR rate was 51%, and the bone marrow MRD-negativity rate was 57% (28/49) [Seymour *et al* Lancet Oncol 2017]. The 24-month estimate for progression free survival was 78.8% and that for duration of response was 87.8% (100% for patients with MRD-negative CR). Of the 28 patients attaining MRD-negativity, 22 achieved the status at 7 months, which was the first mandatory time point for assessment. The remaining six patients achieved MRD-negativity at the second assessment, which ranged from 12 to 22 months, since the timing of this test was not mandated. Twenty (41%) patients discontinued the study. Eleven had progressive disease while on therapy: five with Richter's transformation between 1–9 months and six with CLL progression after a median of 26.4 months (range: 12–37). The other nine patients: withdrew consent (n=3), failed to report for follow-up evaluations (n=1), discontinued due to adverse events related to venetoclax (n=2; tumor lysis syndrome and worsening of peripheral neuropathy), or discontinued due to adverse events considered not related to therapy (n=3). Seventeen patients continue on therapy: 8 MRD-negative CR, 2 MRD-positive CR, 5 MRD-negative PR, and 2 MRD-positive PR. Median duration of response on therapy is 27.9 months (range: 20.3–40.2). Sixteen patients discontinued venetoclax and remained on study as allowed per protocol following the achievement of a deep response (12 MRD-negative CR, 2 MRD-negative PR, 2 MRD-positive CR) (Figure 1). Their median time on venetoclax is 16.3 months (range: 5–38). Twelve of these patients remain in active follow-up and four discontinued without evidence of progression after achieving MRD-negative CR. Two patients with MRD-positive CR had increasing absolute lymphocyte count (ALC) and asymptomatic progression 24 months after stopping venetoclax. Both re-started venetoclax, 2 and 6 months after ALC >5x10^9/L, and achieved partial remissions. The 10 patients with MRD-negativity in the bone marrow who remain in follow-up have a median duration of ongoing response off venetoclax of 13 months (range: 3–34).

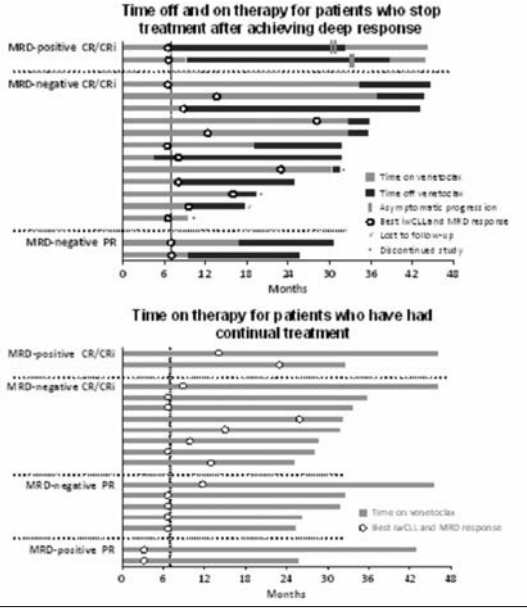

Figure 1.

Summary/Conclusions: Venetoclax with rituximab induces deep and durable responses, with 51% patients achieving CR and 57% achieving marrow MRD-negativity. Patients on continued therapy have durable responses. Additionally, responses are sustained at a median of 13 months among patients who achieve bone marrow MRD-negativity and elected per protocol to stop therapy, demonstrating that it is possible to discontinue venetoclax and maintain prolonged treatment free remission. The 2 patients who progressed at 2 years off therapy responded to the reintroduction of venetoclax.

P248

PREDICTIVE AND PROGNOSTIC IMPACT OF GENE MUTATIONS IN THE CONTEXT OF FLUDARABINE AND CYCLOPHOSPHAMIDE WITH OR WITHOUT OFATUMUMAB TREATMENT IN PATIENTS WITH REL/REF CLL

E. Tausch[1,*], A. Dolnik[1], S. Estenfelder[1], V. Opatrna[1], T. Blätte[1], A. McKeown[2], T. Robak[3], S. Grosicki[4], C. Pallaud[5], D. Mertens[1,6], L. Bullinger[1], H. Doehner[1], S. Stilgenbauer[1]

[1]Department of Internal Medicine III, Ulm University, Ulm, Germany, [2]Novartis, Novartis UK, Uxbridge, United Kingdom, [3]Department of Hematology, Medical university of Lodz, Lodz, [4]Department of Cancer Prevention, Silesian Medical University, Katowice, Poland, [5]Oncology, Novartis Pharma, Basel, Switzerland, [6]Mechanisms of Leukemogenesis, DKFZ Heidelberg, Heidelberg, Germany

Background: Recurrent mutations in genes such as *TP53*, *SF3B1* and *NOTCH1* are frequent in CLL and have in previous studies been associated with outcome. *SF3B1*^{mut}, *TP53*^{mut}, *BIRC3*^{mut} and *XPO1*^{mut} were adverse prognostic factors in patient cohorts with different therapies, and *NOTCH1*^{mut} associated with poor outcome when rituximab was added to standard chemotherapy. This indicated *NOTCH1*^{mut} as a predictive factor in the context of chemoimmunotherapy.
Aims: We assessed the incidence and clinical associations of mutations in *TP53*, *SF3B1, NOTCH1, ATM, BIRC3, FBXW7, MYD88, EGR2 and XPO1* in the COMPLEMENT-2 trial (relapsed/refractory CLL, FC *vs* FC+ofatumumab (FCO), Robak *et al.*, Leuk Lymphoma, 2017).
Methods: Baseline samples were available from 325 of 365 patients (89%) representative of the full analysis set of the clinical trial. Mutation analyses were performed via custom targeted Next Generation Sequencing (tNGS) for *TP53, ATM, BIRC3, FBXW7, MYD88, EGR2 (*all coding exons), SF3B1 (exon 14-16, 18), NOTCH1 (exon 34) and XPO1 (exon 15, 16). All mutations with a variant allelic fraction >5% were considered significant.

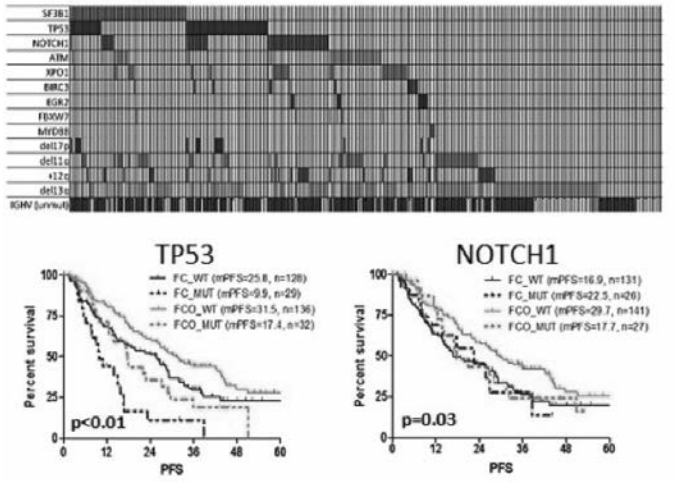

Figure 1.

Results: In total we identified 365 mutations across the 9 genes in 202 of 325 patients (62.2%), with incidences of *SF3B1*^{mut} 19.7%, *TP53*^{mut} 18.8%, *NOTCH1*^{mut} 16.3%, *ATM*^{mut} 13.8%, *XPO1*^{mut} 11.4%, *BIRC3*^{mut} 4%, *EGR2*^{mut} 3.1%, *FBXW7*^{mut} 2.7% and *MYD88*^{mut} 0.9%. We identified a variety of associations of mutational subgroups with genetic, clinical and laboratory parameters, such as *TP53*^{mut} with del17p (p<0.01), *NOTCH1*^{mut}, *FBWX7*^{mut}and *BIRC3*^{mut} with +12q (p<0.01, p=0.01 and p=0.05) and *ATM*^{mut}with del11q (p<0.01). XPO1^{mut} and *ATM*^{mut} associated with unmutated IGHV. CD79B expression on cell surface measured via flow cytometry was lower in *ATM*^{mut} patients, whereas CD20 expression did not differ among the different mutational subgroups. *TP53*^{mut}, *EGR2*^{mut}and*SF3B1*^{mut} patients had worse overall response to therapy (68% p<0.01, 50% p=0.02 and 72% p=0.05 respectively, *vs* 81% overall). Similar to the full analysis set, FCO as compared to FC resulted in significant improved PFS (median 28.1 *vs* 18.8 months, HR=0.67, p<0.01). *TP53*^{mut} and *XPO1*^{mut}were adverse prognostic factors for PFS (HR 1.93 p<0.01 and HR 1.85, p<0.01 respectively), but only *TP53*^{mut} for decreased OS (HR 2.11 p<0.01). All other mutations, in particular *SF3B1*^{mut} and *NOTCH1*^{mut}, did not significantly impact PFS or OS. To identify factors of independent clinical

impact, we performed multivariable Cox regressions for PFS and OS including treatment, IGHV status and all cytogenetic and mutational subgroups. For PFS, the following independent prognostic factors were identified: FCO therapy (HR 0.64 p<0.01), del17p (HR 5.08 p<0.01), unmutated IGHV (HR 2.0 p<0.01), *TP53*^{mut} (HR 1.75 p<0.01) and *XPO1*^{mut}(1.86 p<0.01). Del17p (HR 4.79 p<0.01), unmutated IGHV (HR 1.69 p=0.04) and *TP53*^{mut} (HR 1.76 p=0.03) were identified as independent prognostic factors for OS. With focus on the predictive value of gene mutations, we found a beneficial effect of the addition of ofatumumab to chemotherapy irrespective of *TP53* mutation (HR 0.52 p=0.02 for *TP53*^{mut} and HR 0.68, p=0.02 for *TP53*^{wt}). Regarding *NOTCH1,* ofatumumab was only beneficial in *NOTCH1*^{wt} but not in *NOTCH1*^{mut} patients (HR 0.64, p<0.01 and HR 0.86, p=0.67) (Figure 1).

Summary/Conclusions: In the COMPLEMENT-2 trial evaluating FCO against FC in relapsed/refractory CLL patients, we found *TP53*^{mut} and *XPO1*^{mut} but not *SF3B1*^{mut} or *NOTCH1*^{mut} as independent prognostic factors for PFS. Notably, a benefit of ofatumumab addition to FC treatment was observed among *NOTCH1*^{wt} but not among *NOTCH1*^{mut} patients indicating *NOTCH1* mutation status as a predictive marker in the context of type-1 CD20 antibody addition to chemotherapy.

P249

RESULTS OF A PHASE II MULTICENTER STUDY OF OBINUTUZUMAB PLUS BENDAMUSTINE IN PTS WITH PREVIOUSLY UNTREATED CHRONIC LYMPHOCYTIC LEUKEMIA

A. Danilov[1,*], H. Yimer[2], M. Boxer[3], N. Di Bella[4], S. Babu[5], J. Li[6], Y. Mun[6], S. Skettino[6], J. Sharman[7]

[1]Oregon Health and Science University, Portland, [2]Texas Oncology, Tyler, [3]Arizona Oncology, Tucson, [4]Rocky Mountain Cancer Centers, Aurora, [5]Fort Wayne Medical Oncology, Fort Wayne, [6]Genentech Inc., South San Francisco, [7]Willamette Valley Cancer Institute and Research Center, Eugene, United States

Background: Bendamustine (B) plus rituximab (R; BR) is a commonly used first-line (1L) treatment for chronic lymphocytic leukemia (CLL). The CLL10 study reported an overall response rate (ORR) of 96% and complete response (CR) rate of 31% with BR. Obinutuzumab (GA101; G) is a glycoengineered, type II anti CD20 monoclonal antibody. A randomized Phase III trial in 1L CLL pts showed that G significantly improved progression-free survival (PFS) and CR rate compared with R, when used in combination with chlorambucil (Goede 2014). B plus G (BG) was evaluated in a subgroup of CLL pts in the GREEN study (Stilgenbauer 2015).

Aims: The aim of this Phase II study (NCT02320487) is to evaluate the efficacy and safety of BG as 1L treatment for CLL pts.

Methods: 102 pts with previously untreated CLL received BG, consisting of 6 cycles of G (cycle [C] 1: 100mg day (D) 1, 900mg D2, 1000mg D8 and D15; C2–6: 1000mg D1) and B (90mg/m^2: C1, D2 and D3; C2–6, D1 and D2). Each cycle was 28 days. The primary endpoint was CR assessed using iwCLL criteria. Secondary endpoints included ORR, PFS, overall survival, and minimal residual disease (MRD). Median follow-up at the time of analysis was 11.0 months.

Results: Median pt age was 61 yrs (range 35–90); 68.6% were male; 44.1% had Rai stage 3–4. For evaluated pts, IgVH status was 32.9% mutated and 67.1% unmutated. The incidences of trisomy 12, normal cytogenetics, and deletions of 13q, 11q, and 17p were 23.4%, 37.5%, 17.2%, 15.6%, and 6.3%, respectively. Investigator-assessed CR rate was 49.0% (95% CI 39.0–59.1) and ORR was 89.2% (95% CI 81.5–94.5) after 6 cycles. MRD negativity in blood, as measured by 4-color flow cytometry, was achieved in 42.7% of pts at the end of induction response assessment and in 75.5% of pts at any time following treatment. MRD negativity in bone marrow (BM) was 60.8% in pts with BM samples. The most common adverse events (all grades [Gr]) were infusion reactions (72.5%), nausea (52.0%), pyrexia (36.3%), neutropenia (34.3%), fatigue (34.3%), constipation (26.5%), and rash (26.5%). The most common Gr 3–4 adverse event was neutropenia (26.5%). Incidence of Gr 3–4 infections was 11.8%. Incidence of tumor lysis syndrome was 4.9% (all Gr 3). Three pts died; none were deemed related to study treatment or CLL by investigators.

Summary/Conclusions: BG is an effective regimen for 1L treatment of CLL pts, inducing a high CR rate after 6 cycles of therapy. No unexpected safety signals were observed.

P250

RELATIVE SURVIVAL REACHES A PLATEAU IN HAIRY CELL LEUKEMIA: A POPULATION-BASED STUDY ON INCIDENCE, PRIMARY TREATMENT AND SURVIVAL AMONG 1,427 PATIENTS DIAGNOSED IN THE NETHERLANDS, 1989-2014

A. Dinmohamed[1,2,3,*], O. Visser[4], W. Posthuma[5], R. Raymakers[6], J. Doorduijn[3]

[1]Research, Netherlands Comprehensive Cancer Organisation (IKNL), [2]Public Health, Erasmus University Medical Center, Utrecht, [3]Hematology, Erasmus MC Cancer Institute, Rotterdam, [4]Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [5]Internal Medicine, Reinier de Graaf Gasthuis, Delft, [6]Hematology, Utrecht University Medical Center, Utrecht, Netherlands

Background: The introduction of cladribine and pentostatin has revolutionized the management of HCL as from the late 80s. As a result of that revolution, HCL patients (pts) are rarely included in clinical trials. Population-based studies can inform on issues related to outcomes of HCL pts managed in daily practice. At present, however, population-based studies that assess patterns of incidence, treatment and survival in HCL are very scarce.

Aims: The aim of this comprehensive nationwide population-based study was to assess trends in incidence, primary treatment and survival among HCL pts diagnosed in the Netherlands.

Methods: We selected all adult (≥18 years) pts diagnosed with classic HCL in the Netherlands between 1989-2014 from the nationwide Netherlands Cancer Registry with survival follow-up through February, 2016. Age-standardized incidence rates (ASR) were calculated per 1,000,000 person-years and standardized according to the European standard population. Data on primary treatment (*i.e.* no therapy, chemotherapy [CT] and immumotherapy [IT]) were available for individual pts. Pts were categorized into 2 periods (1989-2000 and 2001-2014) and 3 age groups (18-59, 60-69 and ≥70 years). We calculated relative survival (RS) and the relative excess risk of mortality as measures of disease-specific survival.

Results: We included a total of 1,427 newly diagnosed HCL pts in the study (median age, 59 years; age range, 22-95 years; 77% males). The annual ASR of HCL remained quite stable over time and was 3.1 and 3.3 in the first and last period, respectively. Men had a higher overall incidence than women (5.3 *v* 1.3 in 2001-2014). The age-specific incidence rates for males were 5.5, 15.0 and 15.3 in 2001-2014 for the three age groups. The corresponding rates for females were 1.2, 3.1 and 5.5. The application of CT increased over time for all age groups. The proportions of CT for the three age groups were 56, 51 and 34% in 1989-2000, as compared with 81, 73 and 53% in 2001-2014. The corresponding proportions for IT were 21, 13 and 17% in 1989-2000, as compared with 2, 1 and 4% in 2001-2014. Lastly, the corresponding proportions for pts who did not receive therapy were 23, 36 and 49% in 1989-2000, as compared with 17, 26 and 42% in 2001-2014. Overall, when corrected for age and sex, pts diagnosed in 2001-2014 had 49% lower excess mortality during the first 10 years after HCL diagnosis, as compared with pts diagnosed in 1989-2000 (*P*=.005). Ten-year RS (95% confidence intervals) was impressive for pts age 18-59, namely 92% (88% - 96%) and 98% (94% - 100%; *P*=.176) in the first and last period, respectively (Figure 1a). Most of the significant improvement was observed in pts age ≥60. More specifically, 10-year RS for pts age 60-69 increased from 82% (71% - 92%) to 99% (89% - 106%; *P*=.009; Figure 1b), and for pts age ≥70 from 67% (49% - 86%) to 85% (68% - 102%; *P*=.366; Figure 1c) between the first and last periods. In addition, older age (*P*<.001), but not sex (*P*=.058), was associated with higher excess mortality.

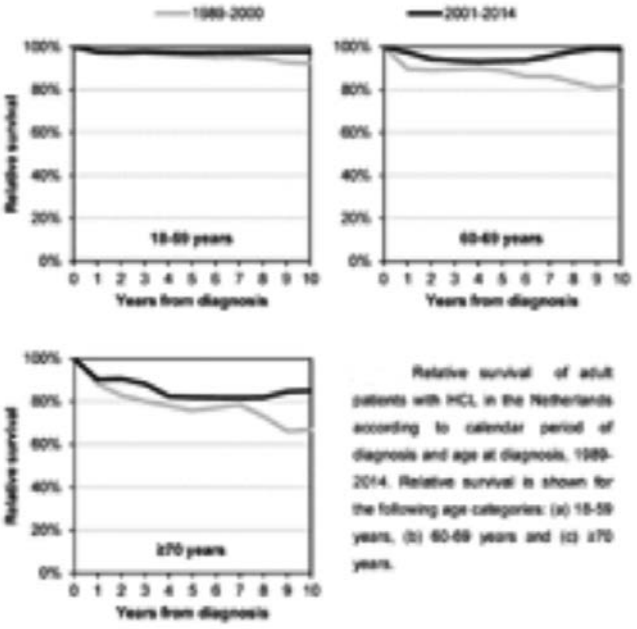

Figure 1.

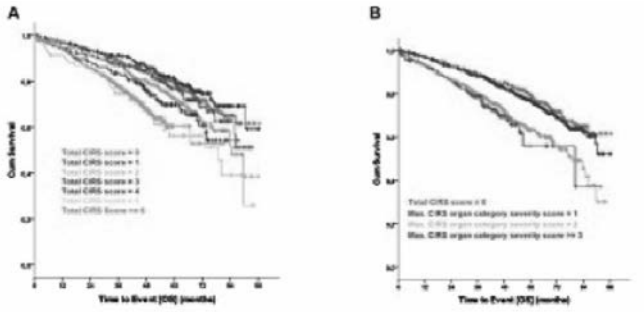
Summary/Conclusions: The incidence of HCL remained stable during a 26-year period in the Netherlands. RS for pts diagnosed in the period 2001-2014 eventually reached a plateau, indicating that by then their survival is comparable to that of the general population. Survival was already excellent for younger patients throughout the entire study period. Survival improvement was most pronounced for pts age ≥60, although it was not statistically significant for pts age ≥70. This could be explained by the increased use CT over time. Population-based cancer registries are useful instruments to assess outcomes of pts rarely included in clinical trials.

P251

CUMULATIVE ILLNESS RATING SCALE PROVIDES PROGNOSTIC INFORMATION BEYOND THE INTERNATIONAL PROGNOSTIC INDEX FOR CHRONIC LYMPHOCYTIC LEUKEMIA: AN ACROSS-TRIAL ANALYSIS BY THE GCLLSG

V. Goede[1,2,*], J. Bahlo[1], S. Robrecht[1], O. Al-Sawaf[1], A.-M. Fink[1], C.-M. Wendtner[3], S. Stilgenbauer[4], K. Fischer[1], B. Eichhorst[1], M. Hallek[1,5]
[1]Dept. I of Internal Medicine, University Hospital Cologne, [2]Oncogeriatrics Unit, St. Marien Hospital, Cologne, [3]Klinikum Munich-Schwabing, Munich, [4]University Hospital Ulm, Ulm, [5]Centre of Integrated Oncology (CIO) Cologne-Bonn, Cologne, Germany

Background: CLL-IPI is a prognostication tool to stratify patients with chronic lymphocytic leukemia (CLL) for low, intermediate, high, or very high risk. CLL-IPI uses age, Binet stage, beta-2-microglobulin, 17p deletion / *TP53* mutation, IGHV mutational status, but not comorbidity as weighted factors to model prognosis. CIRS is a tool which allows assessing and quantifying burden of comorbidity in individual patients.
Aims: To validate CIRS in CLL and to assess whether CIRS is of further value when estimating prognosis by CLL-IPI in CLL.
Methods: This is a comprehensive evaluation of CIRS in 2158 patients pooled from the CLL8, CLL10, and CLL11 trials of the German CLL Study Group (GCLLSG). Median observation time was 55 months. All patients had CIRS data prospectively assessed prior to study treatment (689 FCR, 409 FC, 279 BR, 333 GCLB, 330 RCLB, 118 CLB).



C

COX regression (Overall survival)	Comparison	Hazard ratio	95% Confidence interval: Lower	Upper	p value

Intermediate	vs. low	1.474	0.655	3.313	0.348
High	vs. low	3.029	1.413	6.492	0.004
Very high	vs. low	5.201	2.274	11.896	<0.001

Figure 1.

Results: Median age was 64 years; 69% of patients were males, and 50% had ECOG performance score of 1 or higher. Complete information on age, Binet stage, b_2-microglobulin, 17p deletion and/or *TP53* mutation, and IGHV mutational status was available in 1761 of the 2158 patients. Distribution of CLL-IPI risk groups was as follows: 275 (16%) low risk, 653 (37%) intermediate risk, 712 (40%) high risk, 121 (7%) very high risk. The median total CIRS score was 3 (range 0-22); 81% of the patients had a total CIRS score of at least 1 and 28% of greater than 6. Comorbidities were most frequently captured under the following CIRS organ categories: cardiac, blood pressure, respiratory, musculoskeletal, or endocrine/metabolic. A severity score of >=2 and >=3 in at least one CIRS organ category was present in 46% and 11% of the patients, respectively. There was a positive correlation between total CIRS score and age (r_s=0.5, p<0.001) as well as ECOG performance score (r_s=0.4, p<0.001) and an inverse association between total CIRS score and creatinine clearance (r_s=-0.3, p<0.001). In univariate analysis, increased total CIRS score was associated with shorter overall survival (OS); with poorer OS determined by severity rather than numbers of comorbidities (log-rank: p<0.001, Figure 1A and 1B). In multivariate analysis, total CIRS score was an independent risk factor for OS when used as continuous or categorical variable together with age, gender, Binet stage, ECOG performance score, thymidine kinase, beta-2-microglobulin, IGHV, and 17p deletion (adjusted for treatment intensity). Total CIRS score also remained an independent risk factor for OS when added to the CLL-IPI. Weight of CIRS was highest in the CLL8 and lower in the CLL10 and CLL11 trials as expressed by the hazard ratios (Figure 1C). There was no significant association between total CIRS score and progression-free survival or time-to-next treatment. However, increased total CIRS score was associated with higher risk of grade 3/4 adverse events as well as premature treatment discontinuation during or after treatment with FCR / FC / BR but not GCLB / RCLB / CLB.
Summary/Conclusions: Findings suggest that CIRS provides prognostic information beyond the CLL-IPI. Systematic comorbidity assessment (*e.g.* by CIRS) in addition to the CLL-IPI therefore appears reasonable when estimating overall prognosis and deciding treatment in CLL.

P252

A PHASE II RANDOMISED STUDY INVESTIGATING THE EFFICACY OF STANDARD OR HIGH-DOSE OFATUMUMAB IN COMBINATION WITH CHEMOTHERAPY IN RELAPSED CHRONIC LYMPHOCYTIC LEUKAEMIA

D. Allsup[1,2,*], D. Howard[3], T. Munir[4], A. Hockaday[3], A. Rawstron[5], L. Collett[3], L. McParland[3], J. Oughton[3], A. Bloor[6], D. Phillips[3], A. Nathwani[7], P. Shankara[8], D. Turner[9], P. Hillmen[4]
[1]Haematology, Hull and East Yorkshire NHS Trust, [2]Haematology, Hull York Medical School, Hull, [3]Clinical Trials Research Unit, University of Leeds, [4]St James Institute of Oncolgy, [5]Haematological Malignancy Diagnostic Service, St James University Hospital, Leeds, [6]Haematology, The Christie NHS Foundation Trust, Manchester, [7]Haematology, University College London Hospital, London, [8]Haematology, Birmingham Heartlands Hospital, Birmingham, [9]Haematology, Torbay District Hospital, Torquay, United Kingdom

Background: The outcome of CLL patients relapsing after chemoimmunotherapy (CIT) has been transformed by targeted therapies, however a proportion of such patients may be successfully retreated with CIT. CD20-monoclonal-antibody-based CIT has been successfully deployed for the retreatment of relapsed patients but the optimum dosage of antibody is unknown.
Aims: COSMIC (Chemotherapy plus Ofatumumab at Standard or Mega dose In CLL) was a phase II randomised study assessing the efficacy of standard (sOf) and high (megaOf) dose ofatumumab in combination with either fludarabine cyclophosphamide (FC) or bendamustine (B). The primary endpoint was complete response (CR/CRi) rate independently assessed 3 months post-therapy. Secondary endpoints were the proportion of participants with undetectable minimal residual disease (MRD); overall response rate; progression-free survival; overall survival; time to MRD relapse; dynamics of MRD relapse; safety and toxicity. Using the A'Hern exact one-stage design with 80% power and 1-sided type 1 error of 5%, 10 CRs were required from 37 recruits in either arm to justify further investigation in a phase III study. Total sample size was intended to be 82 allowing for drop-outs.
Methods: CLL patients relapsing after a minimum of 6 months from the most recent course of chemotherapy, and fit for FC or B, were eligible. Treatment comprised sOf (total 6.3g of ofatumumab: 0.3g day 1 cycle 1, 1.0g day 8 cycle 1, 1.0g day 1 monthly cycles 2-6), or megaOf (total 22.3g of ofatumumab: 0.3g day 1 cycle 1, 2.0g weekly for remainder of monthly cycles 1-2, 2.0g day 1 cycles 3-6) given in combination with FC or B at conventional doses. The choice of FC or B was decided pre-randomisation by the local investigator.
Results: Recruitment was slow with 61 patients randomised and treated, sOf (32: 21 FC and 11 B), and megaOf (29: 17 FC and 12 B). 77% were previously treated with purine analogues and 79% had experienced a remission of greater than 24 months after their most recent therapy. 26% had an 11q deletion and 67% had unmutated VH genes or expressed VH3-21.
With 61 participants, there was 71% power to observe 8 CRs from 28 participants in either arm. In the intention-to-treat (ITT) population 6(19%) sOf and 7(24%) megaOf patients achieved a CR/CRi; 22(69%) sOf and 21(72%) megaOf did not; and 4(12%) sOf and 1(4%) megaOf were unassessable. Rates were similar between FC(26%) and B(19%). Overall responses (CR/CRi+PR) were achieved in 20(63%) sOf and 20(69%) megaOf patients. In the ITT population, 4(13%) sOf and 6(21%) megaOf patients were MRD negative in marrow 3 months post-therapy. Overall, therapy was deliverable with 66% of participants receiving the proscribed 6 cycles of CIT (19(59%) sOf, 21(72%) megaOf). 42 serious adverse reactions were reported (21 sOf, 21 megaOf), 28(67%) being grade 3 or above (13(62%) sOf, 15(71%) megaOf), with the commonest events related to infections (45%) and cytopenias (21%). There was one treatment-related death (sOf-FC).
Summary/Conclusions: The CR rates observed in both treatment arms failed to meet pre-specified levels for the primary endpoint. Response rates observed in both arms are comparable to those obtained in previous studies of CIT in this group and suggest that dose escalation of ofatumumab in relapsed CLL does not lead to a worthwhile improvement in outcomes. However, CIT is deliverable with acceptable toxicity and should still be considered an option, particularly for patients with long-remissions to first line therapy and who do not possess high-risk cytogenetic markers.

FINAL RESULTS OF THE PHASE IB GALTON TRIAL IN CHRONIC LYMPHOCYTIC LEUKEMIA: DURABLE REMISSIONS WITH FRONTLINE OBINUTUZUMAB (G) PLUS FLUDARABINE/CYCLOPHOSPHAMIDE (G-FC) OR BENDAMUSTINE (G-B)

J. Brown[1,*], S. O'Brien[2], C.D. Kinglsey[3], H. Eradat[4], J.M. Pagel[5,6], C. Vignal[7], J. Hirata[8], T.J. Kipps[9]
[1]Dana-Farber Cancer Institute (CLL Research Consortium), Boston, [2]MD Anderson Cancer Center, University of Texas, Houston, [3]Clearview Cancer Institute, Huntsville, [4]University of California, Los Angeles, [5]Fred Hutchinson Cancer Research Center, [6]University of Washington, Seattle, United States, [7]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [8]Genentech, Inc., South San Francisco, [9]Moores Cancer Center (CLL Research Consortium), University of California, San Diego, United States

Background: GALTON was an open-label, parallel-arm, non-randomized, multicenter, Phase Ib study (NCT01300247) investigating safety and preliminary efficacy of G-FC or G-B in previously untreated CLL.
Aims: We report final results for the planned 36-months' (mo) follow-up (35/41 pts; median observation 40.4 [17.6–43.6] mo); initial results were reported previously (Brown *et al.* 2015).
Methods: Eligible pts met iwCLL 2008 criteria for therapy, were considered fit for chemoimmunotherapy by the investigator, and provided informed consent. Each center selected treatment (G-FC or G-B) for their pts. G was administered intravenously (IV; 100mg day [D] 1, 900mg D2, 1000mg D8 and 15 cycle [C] 1; 1000mg D1 C2–6) with FC (fludarabine 25mg/m^2 IV and cyclophosphamide 250mg/m^2 IV D2–4 C1, D1–3 C2–6) or B (90mg/m^2 IV D2–3 C1, D1–2 C2–6). Each cycle was 28 days. The primary endpoint was safety and tolerability of G-chemotherapy.
Results: 21 pts were enrolled in the G-FC arm and 20 in the G-B arm. Median age was 60 (25–80) years, 78% of pts were male, and around one-third had Rai stage III/IV disease. Median time from diagnosis to therapy was 24 mo (G-FC) and 32 mo (G-B). At data cut-off, 37 pts were alive in follow-up: G-FC (n=18: 2 lost to follow-up) and G-B (n=19). 1 event of progressive disease occurred in each arm, and 1 pt per arm died due to an adverse event (AE; G-B: respiratory failure; G-FC: unknown in the setting of unresolved Grade (Gr) 4 pancytopenia); neither was considered treatment related. Due to the small number of events, median PFS and OS could not be estimated; however, 3-year OS was 95% for each arm (95% CI G-FC, 68–99; G-B, 70–99). Post-treatment, 10/41 pts (24.4%) experienced ≥1 Gr3–5 AE: 2/21 pts (9.5%) in the G-FC arm and 8/20 pts (40.0%) in the G-B arm. 7 serious AEs were reported in 4 pts, all in the G-B arm; these included pneumonitis and respiratory failure (as noted above; both Gr5), Gr4 leukopenia/neutropenia, small cell lung cancer and Gr4 pneumothorax, and melanoma. During follow-up, 6 pts had ≥1 Gr3–4 AE of neutropenia, including 4/20 pts (20.0%) in the G-B arm and 2/21 pts (9.5%) in the G-FC arm. At end of treatment, all pts were B-cell depleted (B-cell count <0.07x10^9/L). Within 6–12 mo of follow-up, very few pts had recovered from B-cell depletion (G-FC: 2/19 pts [10.5%]; G-B: 0/20 pts). At 36 mo follow-up, 9/19 pts (47.3%) in the G-FC arm had recovered, 3/19 (15.8%) were still depleted, and 7/19 did not have data available. In the G-B arm, 6/20 pts (30%) had recovered, 1 was still depleted, and 13/20 had no available data. In a single center exploratory analysis, 9 pts (G-FC) underwent 4-color flow cytometry testing of peripheral blood for minimal residual disease (MRD) 6–14 mo after therapy; all were negative. 8 of these pts (G-FC) who were MRD-negative by 4-color flow cytometry were also tested with the ClonoSEQ immunoglobulin sequencing assay: 4 were MRD-positive and 4 MRD-negative. 4 pts who were MRD-negative with both assays remain in remission, while 2/4 pts who were positive by ClonoSEQ died after follow-up, one of Richter's transformation complicated by pneumonia and the other related to MDS. Another pt who was MRD positive by ClonoSEQ underwent allogeneic stem cell transplantation and remains in remission.
Summary/Conclusions: We conclude that G plus either FC or B results in excellent long-term disease control in previously untreated pts with CLL, and has comparable side-effects to other chemo-immunotherapy regimens.
We thank N Crompton, N Tyson, M Rahman (Roche Products Ltd) and R Morariu-Zamfir (F. Hoffmann-La Roche Ltd) for their support.

THE PROGNOSTIC SIGNIFICANCE OF CLL-IPI AFTER REDUCED INTENSITY CONDITIONING ALLOGENEIC STEM CELL TRANSPLANT IN CHRONIC LYMPHOCYTIC LEUKEMIA: THE MAYO CLINIC EXPERIENCE

T. Anagnostou[1,*], T.D. Shanafelt[1], M.S. Patnaik[1], M.C. Larson[1], K.G. Chaffee[1], S.A. Parikh[1], D.A. Gastineau[1], W. Ding[1], T.G. Call[1], M.R. Litzow[1], N.E. Kay[1], M. Conte[1], D.A. Bowen[1], W.J. Hogan [1], S.J. Kenderian[1]
[1]Hematology/Medical Oncology, Mayo Clinic, Rochester, United States

Background: Allogeneic stem cell transplant (SCT) remains the only potentially curative option for chronic lymphocytic leukemia (CLL) patients. However, up to 40% of patients treated with Reduced Intensity Conditioning (RIC) - SCT relapse after transplantation. Recently the CLL International Prognostic Index (CLL-IPI) was validated as a predictor of 5 year overall survival in CLL patients.
Aims: In this analysis, we aimed to elucidate the factors that may predict the outcomesfollowing RIC SCT, including the CLL-IPI.
Methods: This is a retrospective analysis of all CLL patients who underwent RIC-SCT at Mayo Clinic between 2006-2013. The study was approved by the Institutional Review Board. The prognostic value of several CLL, patient and transplant related variables were analyzed. Continuous variables were reported as mean and compared using the T-test. Dichotomous outcomes were compared using the chi-square test. Survival was estimated and compared using the Kaplan Meier and Log Rank tests.
Results: Between 2006 and 2013, 50 patients with a median age of 56 years old underwent RIC-SCT for the treatment of CLL. The median time from diagnosis to RIC-SCT was 4.7 (0.6-22.9) years. Fourteen (28%) patients had 17p deletion at time of transplantation. CLL-IPI prognostic score calculated prior to transplant was intermediate in 30%, high in 42% and very high in 28% of patients. Disease status at the time of transplant was partial or complete remission in the majority of patients (39 patients, 78%). The overall transplant related mortality (TRM) was 6% and the 5-year non-relapse mortality was 14%. Relapse rates at 5 years were 54%. Acute graft *versus* host disease (GVHD) developed in 30 (60%) of patients and chronic GVHD was noted in 32 patients (64%).We evaluated the impact of CLL characteristics, disease status, and patient and transplant characteristics on clinical outcomes. Development of chronic GVHD post-transplant was the dominant predictor of both disease-free survival (DFS) (HR 0.29, 95% CI=0.10-0.69, P=0.006) and OS (HR 0.04, 95% CI=0.01-0.19, P<0.0001, Figure 1A). Very high CLL-IPI risk category (28% of patients) was associated with high relapse rates (82%) post RIC-SCT. DFS was also different between different CLL-PI categories (18.2% in very high 52.9% in high *vs* 66.7% in intermediate, p=0.04, Figure 1B). However, there was no significant difference in overall survival suggesting potential benefits from novel therapies in relapsed patients.Given that development of chronic GVHD was the most significant predictor for OS, we evaluated what pre-treatment patient, disease (including CLL-IPI), and transplant characteristics predicted for subsequent development of chronic GVHD. ZAP70 over expression (OR 0.09 [95% CI 0.01-0.79], p=0.03), disease status at transplant (progression *versus* remission OR 0.22 [95% CI 0.05-0.92], p=0.038), and alemtuzumab exposure within 3 months of transplantation were associated with lower rates of chronic GVHD (OR 0.08 [95% CI 0.01-0.79], p=0.03). CLL-IPI was not a significant predictor for the development of chronic GVHD in our analysis.

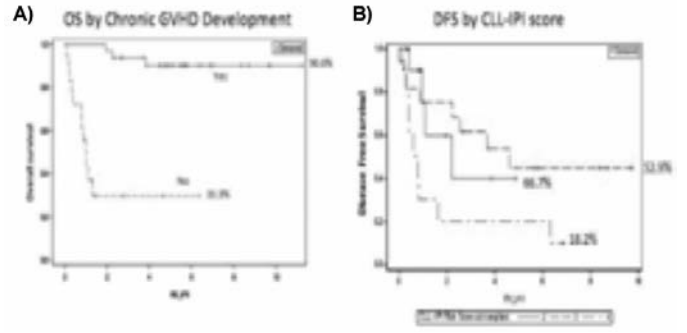

Figure 1.

Summary/Conclusions: This study found that the development of chronic GVHD post-transplant is themost significant predictor for both OS and DFS in surviving patients after RIC-SCT in CLL. Interestingly, 82% of patients with very high risk CLL-IPI relapsed after RIC-SCT. This is the first report to evaluate the prognostic significance of CLL-IPI for stratifying post-transplant outcomes and to identify high relapse rates in the very high risk CLL-IPI category.

Background: Several studies showed that tyrosine kinase inhibitors (TKIs) can safely be discontinued in patients with sustained deep molecular response. So far, deep molecular response (DMR) and treatment duration were predictive for successful treatment-free remission (TFR) whereas age, risk scores, gender and molecular response level before stopping were without influence (Mahon FX. *et al.* and Pfirrmann M. *et al.*, ASH 2016). In addition, biomarkers like NK-cells and CD86+ cells (Ilander M. *et al.* and Schütz C. *et al.*, Leukemia 2017) seem to be of impact. *ABCG2, OCT1* and *ABCB1* are known to play a crucial role in acquired pharmacokinetic drug resistance and DMR in the context of nilotinib, imatinib and dasatinib. The influence of these mechanisms have not yet been analyzed for their correlation with TFR.

Aims: In a substudy of the EUROSKI trial, expression levels of the influx transporter *OCT1* and the efflux transporters *ABCG2* and *ABCB1* (*MDR1*) have been quantified in order to investigate their impact on TFR. As all patients are in DMR, we investigate whether these transporters confer a constitutional disposition for TFR.

Methods: The expression levels of *OCT1, ABCG2* and *ABCB1* have been determined by an absolute transcript quantification method in the peripheral blood of patients, enrolled in the EUROSKI trial and screened in our center. Minimal inclusion criteria were three years TKI treatment and one year MR^4 duration (*BCR-ABL*^{IS} <0.01%). Plasmid standards have been designed including the genes *OCT1, ABCG2, ABCB1* together with *GUS* as reference gene. Expression measurements were performed by qRT-PCR on baseline (day of stopping TKI treatment) samples. Cutoff levels were determined by the minimal p-value approach and adjusted for multiple testing by the Bonferroni method. The predictive significance of the efflux and influx channel transcript levels was quantified by a multivariate Cox's regression model. Relapse has been defined as loss of major molecular response at one time point.

Results: In our cohort, 132 chronic phase CML patients discontinued TKI treatment (87% imatinib 1st line treatment), showing a relapse rate of 46%. Median MR^4 and TKI treatment duration was 4.3 and 7.6 years respectively. The majority of patients were positive for the e14a2 transcript (e14a2+: 63%, e13a2+: 28%, e13a2+/e14a2+: 9%). The mean expression of *OCT1* and *ABCB1* between 'relapse' and 'no-relapse' patients showed no significant difference (p=0.99 and p=0.66), whereas *ABCG2* showed a weak differential expression (1.1% *vs* 0.8%, p=0.065). Cutoff analyses showed a significant risk stratification only for the *ABCG2* efflux transporter at a distinct cutoff value of 4.5‰ (p=0.04). Patients with an *ABCG2/GUS* transcript level above 4.5‰ (n=93) had a 30-months TFR of 47%, whereas patients with low *ABCG2* expression (<4.5‰, n=39) showed a 12-months TFR of 67%. The hazard ratio and predictive significance of the *ABCG2* transcript levels were investigated by a multivariate Cox's regression model. Only *ABCG2* expression was retained as independent covariate in this model (p=0.033). Thus, patients with an *ABCG2/GUS* transcript level above 4.5‰ showed an up to two-time higher risk of relapse after treatment discontinuation (HR=2.1, 95% CI: 1.06-4.05).

Summary/Conclusions: Here we investigated for the first time the impact of pharmacokinetics in the context of a CML discontinuation trial. *ABCG2* but not *OCT1* and *ABCB1 (MDR1)* predicted treatment-free remission after TKI discontinuation. High expression of the *ABCG2* efflux transporter correlated with a two-time higher risk of relapse in multivariate analysis. Further prospective validation is warranted.

P256

HLA-G MOLECULES AND CLINICAL OUTCOME IN CHRONIC MYELOID LEUKEMIA

G. Caocci[1,*], M. Greco[2], M. Arras[2], R. Cusano[3], S. Orru[4], B. Martino[5], E. Abruzzese[6], S. Galimberti[7], O. Mulas[1], M. Trucas[1], R. Littera[4], S. Lai[4], C. Carcassi[4], L. N. Giorgio[1]

Eugenio Hospital, Tor Vergata University, Rome, [7]Department of Clinical and Experimental Medicine, Section of Hematology, University of Pisa, Pisa, Italy

Background: The human leukocyte antigen-G (HLA-G) gene encodes a tolerogenic protein known to promote tumor immune-escape mechanisms.

Aims: We investigated the potential role of HLA-G polymorphisms and soluble HLA-G molecules in susceptibility to chronic myeloid leukemia (CML), as well as in achievement and maintenance of deep molecular remission ($MR^{4.5}$) in 68 patients treated with tyrosine kinase inhibitors (TKIs).

Methods: The entire HLA-G gene was amplified by long-range PCR and sequenced using next-generation sequencing (NGS) with Illumina's Nextera® technology and a 300 bp paired-end read protocol. The BioVendor sHLA-G ELISA (RD194070100R sHLA-G ELISA - EXBIO Praha a.s. BioVendor) immunoassay was used for the quantitative measurement of HLA-G1 and HLA-G5 soluble forms in EDTA-plasma samples

Results: The frequency of the G*01:03 allele was significantly associated to CML (10,29% *vs* 4,46; p=0.001). Patients carrying the G*01:01:01 or G*01:01:02 allele had a significantly higher mean value of soluble HLA-G compared to patients carrying G*01:01:03 (109.2±39.5 *vs* 39.9±8.8 units/ml; p=0.03), and showed significantly lower EFS compared to patients with other allelic combinations (62.3% *vs* 90.0%; p=0.05). Moreover patients carrying the G*01:01:03 allele had significantly higher rates of $MR^{4.5}$ (100% *vs* 65%), with earlier achievement of deep $MR^{4.5}$ (median of 8 *vs* 58 months, p=0.001). TKIs were discontinued in 24 patients after 2 years of confirmed $MR^{4.5}$. Treatment free remission (TFR) was 57.7%. None of the patients homozygous for the G*01:01:01 or G*01:01:02 allele remained in TFR (0% *vs* 68.4%, p=0.023) (Figure 1). All patients carrying the G*01:01:03 allele remained in TFR.

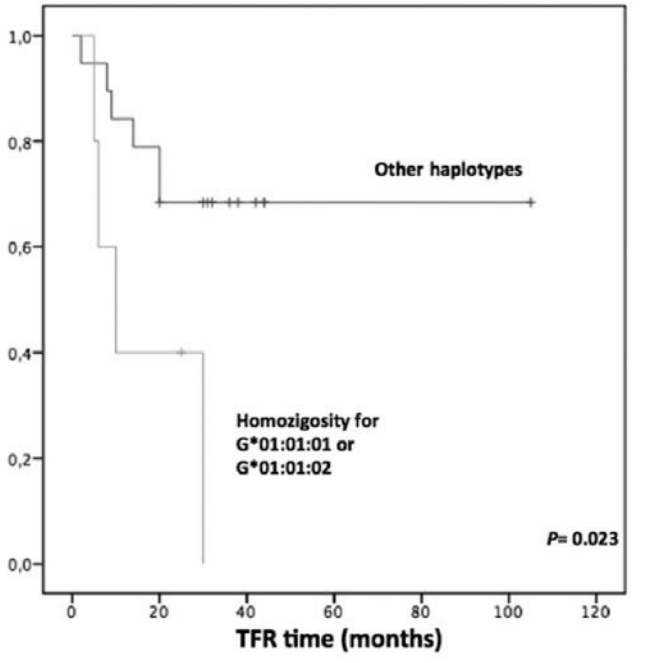

Figure 1.

Summary/Conclusions: HLA-G alleles with higher secretion of soluble HLA-

G would seem to be associated with lower EFS and TFR, possibly because of a stronger inhibitory effect on the immune system in favor of tumor escape mechanisms. Conversely, the allele associated to lower levels of sHLA-G promoted achievement of $MR^{4.5}$ and TFR, suggesting increased cooperation of the host immune system in CML cell clearance.

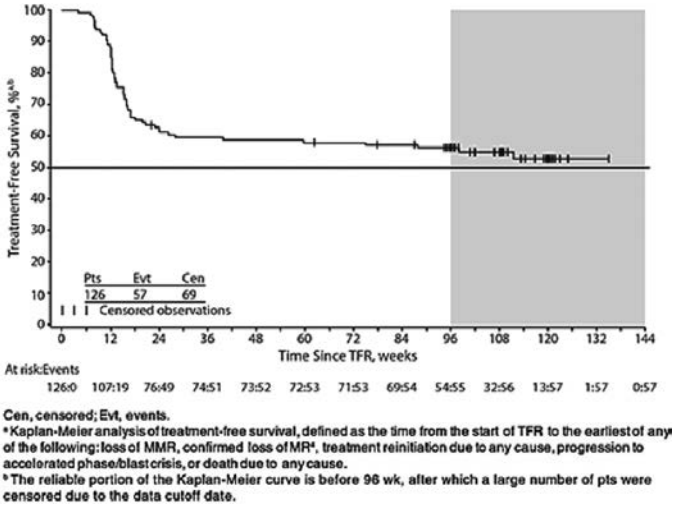
Background: ENESTop (NCT01698905) is evaluating the ability to stop treatment and remain in TFR in pts with CML-CP who achieved a sustained deep molecular response (MR) after switching from imatinib (IM) to NIL. In the primary analysis, 57.9% of pts (73/126) who stopped treatment remained in TFR (no loss of major MR [MMR; *BCR-ABL1* ≤0.1% on the International Scale (IS)], no confirmed loss of MR^4 [*BCR-ABL1*^{IS} ≤0.01%], and no treatment reinitiation) at 48 wk.

Aims: To evaluate the proportion of pts remaining in TFR at 96 wk after stopping second-line NIL in ENESTop.

Methods: Eligible pts had ≥3 y of prior tyrosine kinase inhibitor treatment (>4 wk IM, then ≥2 y NIL) and achieved $MR^{4.5}$ (*BCR-ABL1*^{IS} ≤0.0032%) after switching to NIL. All pts provided informed consent. Enrolled pts continued NIL for 1 y in the consolidation phase (MR assessed every 12 wk). Pts without confirmed loss of $MR^{4.5}$ during consolidation were eligible to enter the TFR phase (MR assessed every 4 wk for the first 48 wk, every 6 wk for the second 48 wk, then every 12 wk). Pts with loss of MMR or confirmed loss of MR^4 reinitiated NIL. This analysis was conducted when all pts who entered the TFR phase had completed 96 wk of TFR, reinitiated treatment, or discontinued from the study (data cutoff, 7 Nov 2016).

Results: At 96 wk of the TFR phase, 67 of the 126 pts (53.2% [95% CI, 44.1% - 62.1%]) who entered the TFR phase remained in TFR. Four pts who were in TFR at 48 wk reinitiated NIL due to confirmed loss of MR^4 at 60, 72, 90, and 96 wk, respectively. Two other pts discontinued from the study between 48 and 96 wk due to pregnancy (last *BCR-ABL1*^{IS} of 0.0035% at 60 wk) and pt decision (maintained $MR^{4.5}$ through 90 wk), respectively. Based on Kaplan-Meier analysis, the median duration of treatment-free survival has not been reached and the curve appeared to plateau (Figure 1). Of 56 pts who reinitiated NIL by the data cutoff, 52 (92.9%) regained MR^4 and $MR^{4.5}$, and the time by which 50% regained MR^4 and $MR^{4.5}$ was 12.0 and 13.1 wk, respectively. The time by which 50% of pts regained $MR^{4.5}$ was shorter for pts who reinitiated NIL due to confirmed loss of MR^4 (n=22; 11.0 wk) *vs* loss of MMR (n=34; 16.0 wk). Two of the 4 re-treated pts who did not regain MR^4 were ongoing in the treatment reinitiation phase (duration, 87.9 and 6.9 wk, respectively); the other 2 discontinued from the study before 48 wk, 1 due to not regaining MMR (retreatment duration, 20 wk) and 1 due to an adverse event (AE) after regaining MMR. Two deaths occurred after the first 48 wk of TFR, both in post-treatment follow-up: 1 due to cardiopulmonary failure 111 days after pt discontinued retreatment due to an AE, and 1 due to adenocarcinoma 77 days after pt discontinued retreatment due to initiation of chemotherapy for secondary malignancy. Among pts who remained in TFR for >48 wk (n=73), rates of all-grade AEs were 82.2% and 63.0% during the first and second 48 wk of TFR, respectively, *vs* 79.5% during the consolidation phase. Rates of musculoskeletal pain-related AEs were 47.9% and 15.1% during the first and second 48 wk of TFR, respectively, *vs* 13.7% during the consolidation phase.

Summary/Conclusions: Updated 96-wk analyses from ENESTop showed stability of the TFR rate, with few pts reinitiating treatment between 48 and 96 wk after stopping second-line NIL. Rates of overall and musculoskeletal pain-related AEs decreased in the second 48 wk of TFR *vs* the first 48 wk. Overall, these results demonstrate the durability of TFR after stopping NIL in pts who achieved a sustained deep MR after switching from IM to NIL.



Cen, censored; Evt, events.
[a]Kaplan-Meier analysis of treatment-free survival, defined as the time from the start of TFR to the earliest of any of the following: loss of MMR, confirmed loss of MR^4, treatment reinitiation due to any cause, progression to accelerated phase/blast crisis, or death due to any cause.
[b]The reliable portion of the Kaplan-Meier curve is before 96 wk, after which a large number of pts were censored due to the data cutoff date.

NILOTINIB-INDUCED METABOLIC DYSFUNCTION: INSIGHTS FROM A TRANSLATIONAL PILOT STUDY USING *IN VITRO* ADIPOCYTE MODELS AND PATIENT COHORTS

S. Sadiq[1], E. Owen[1], T. Foster[1], K. Knight[2], L. Wang[2], M. Pirmohamed[1], R. Clark[3], S. Pushpakom[1,*]

[1]Molecular and Clinical Pharmacology, University of Liverpool, [2]Royal Liverpool and Broadgreen University Hospitals NHS Trust, [3]Institute of Translational Medicine, University of Liverpool, Liverpool , United Kingdom

Background: Impaired glucose and lipid metabolism is an adverse effect associated with nilotinib (NILO), a tyrosine kinase inhibitor (TKI) used in the treatment of chronic myeloid leukaemia (CML). Indeed the 5-year safety analysis of the ENESTnd trial observed elevations in blood glucose and lipid levels in the NILO arms; importantly NILO-treated patients also showed an increased incidence of arterial occlusive events. Adipose tissue is a key regulator of lipid and glucose homeostasis; dysregulation of adipogenesis, altered adipocyte lipid accumulation and reduced insulin sensitivity are implicated in the pathogenesis of metabolic disease. We investigated the effect of NILO on adipose tissue to explain the mechanisms behind NILO-associated metabolic adverse effects.

Aims: i) To study the effect of NILO and imatinib (IMA) on adipocyte function and adipokine secretion using an *in vitro* adipocyte model; ii) To utilise the *in vitro* model to explore potential therapeutic strategies to reverse NILO-mediated effects, and iii) To validate the *in vitro* results in a pilot patient cohort.

Methods: Differentiating 3T3-F442A murine adipocytes were incubated with clinically relevant concentrations of NILO (1-20μM) and IMA (5μM), in the presence or absence of telmisartan (1-10μM), an angiotensin receptor blocker with potential beneficial effects on insulin sensitivity and lipid homeostasis. Cytotoxicity and adipogenesis were assessed by MTT assay and Oil Red O staining, respectively. Expression of adipogenic genes, peroxisome proliferator-activated receptor gamma (*PPARγ*), lipin1 (*LPIN1*), sterol regulatory element-binding protein 1 (*SREBP1*) and glucose transporter 4 (*GLUT4*) were investigated by quantitative PCR and secreted adiponectin was measured by ELISA. Plasma samples were collected from 30 CML patients on either NILO (first line, n=6; second line, n=9) or IMA (first line, n=15) at baseline and at 3 and 12 months of therapy, and adiponectin was measured by ELISA. Data are presented as mean ± SD for 20μM incubations but full concentration response relationships were measured.

Results: Neither NILO nor IMA were cytotoxic to the adipocytes at clinically relevant concentrations. A dose dependent reduction in lipid accumulation was observed for NILO (for 20μM, 0.76 ± 0.005 absorbance units; $p<0.01$) but not IMA (0.98± 0.007), compared to vehicle control. NILO, but not IMA, dose dependently downregulated the mRNA expression of *PPARγ* (52% downregulation), *LPIN1* (28% downregulation) and *SREBP1* (54% downregulation). Both NILO and IMA resulted in significant downregulation of GLUT4 mRNA (NILO, 93%; IMA, 79%; $p<0.01$) and of secreted adiponectin (NILO, 5.99ng/ml; IMA, 31ng/ml; both $p<0.01$ in comparison to vehicle control, 79.2ng/ml). Co-incubation with telmisartan resulted in significant reversal of NILO-mediated effects on lipid accumulation, adipogenic gene expression and adiponectin secretion. In the patient cohort, IMA resulted in a significant increase in adiponectin levels at 3 (38.4±7.1mg/l; $p<0.01$) and 12 (36.7±7.2mg/l; $p<0.01$) month time points compared to baseline (27.3±5.7mg/l). In contrast, second line NILO showed a trend for *reduction* in adiponectin at both 3 (15.2±1.8mg/l; p=NS) and 12

(14.6±1.7mg/l; p=NS) months compared to baseline (21.3±3.4); however this was not evident in the first line NILO-treated group.
Summary/Conclusions: NILO-induced detrimental effects on adipocyte lipid accumulation and adiponectin secretion could be the mechanistic basis for NILO-mediated metabolic dysfunction. This was reversed by telmisartan, a PPARg partial agonist. A larger sample size is required to fully characterise the effect of TKIs on metabolic parameters in the patient population.

P259

EARLY PREDICTION OF THE MOLECULAR RESPONSE TO BCR-ABL1 TYROSINE KINASE INHIBITORS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

Background: A *BCR-ABL1* transcript level at 3 months after the initiation of imatinib therapy has shown to predict the long-term clinical outcomes in patients with chronic myeloid leukemia in chronic phase (CP-CML). The levels obtained earlier than 3 months may also have a similar prognostic significance.
Aims: To assess the prognostic value of the *BCR-ABL1* transcript levels at baseline, and 1 and 3 months after the initiation of a tyrosine kinase inhibitor (TKI) in predicting the major molecular response (MMR) achievement by 12 months, and to compare the patterns of molecular response (MR) to a TKI therapy between good and poor responders using a nonlinear model.
Methods: The clinical data were collected from the 178 patients with newly diagnosed CP-CML who were treated with a TKI at Seoul St. Mary's Hospital. *BCR-ABL1* transcript levels were obtained at baseline, and 1, 3, 6 and 12 months after the initiation of a TKI. The levels were reported as the percent ratio relative to the control gene *ABL1* in accordance with the International Scale (*BCR-ABL1/ABL1*^{IS}[%]). A confirmed MMR was defined as a *BCR-ABL1/ABL1*^{IS}≤0.1% on two consecutive occasions. The predictability of the levels at baseline, and 1 and 3 months post TKI therapy for the achievement of a confirmed MMR by 12 months was evaluated using a logistic regression method with a receiver operating characteristic (ROC) analysis. The areas under the ROC curve (AUCs) were calculated to quantify the predictability. In addition, the patterns of molecular responses over time were described by a nonlinear model to compare the model-derived parameters between the patients who achieved a confirmed MMR by 12 months ("good responders") and who did not achieve the MMR ("poor responders").
Results: Of 178 patients, 67 achieved a confirmed MMR by 12 months but 111 did not. At baseline, the transcript level was not useful to predict the achievement of a confirmed MMR by 12 months. At 1 month post therapy, the levels measured at 1 month significantly (p <0.0001) predicted the MMR with an AUC of 0.77. The patients with the level of 38% or less at 1 month had a better chance to achieve the MMR. By 3 months post therapy, the transcript level measured at 3 months (p <0.0001) accurately predicted the MMR with the AUC of 0.87. The patients with the level of 0.48% or less at 3 months had a better chance to achieve the MMR. A nonlinear sigmoid model was used to fit the transcript data from 149 patients as follows: $MR=MR0\ [1 - t^{\gamma} / (t_{50}{}^{\gamma}+t^{\gamma})]$; where MR0 is the predicted molecular response at baseline; t, time post TKI initiation; γ, slope factor; t_{50}, time required to achieve 50% reduction in MR. Statistically significant differences were observed between the good and poor responders in the median values for the model-derived parameters of MR0 (73.3% *vs* 82.2%; p=0.003), γ (4.98 *vs* 3.32; p <0.0001) and t_{50} (0.95 month *vs* 1.12 month; p=0.002).
Summary/Conclusions: A *BCR-ABL1* transcript level measured at 1 month after the initiation of a TKI may be used as an early indicator to reliably predict the MMR achievement by 12 months in patients with CP-CML. The level obtained at 3 months appears to accurately predict the MMR. Further studies are needed to evaluate the association between the transcript level at 1 month and long-term clinical outcomes.

A HIGH SENSITIVITY HIGH SPECIFICITY DIGITAL PCR ASSAY FOR BCR-ABL

G.-N. Franke[1,*], J. Maier[1], M. Cross[1], S. Tzonev[2], D. Shelton[2], K. Wildenberger[1], D. Niederwieser[1], T. Lange[3]
[1]Abt. Hämatologie und internistische Onkologie, Universitätsklinikum Leipzig AöR, Leipzig, Germany, [2]Digital Biology Center, Bio-Rad Laboratories, Pleasanton, United States, [3]Askepios Klinikum Weißenfels, Weißenfels, Germany

Background: Digital PCR (dPCR) generates an absolute read out that is largely robust to variations in PCR efficiency and should reduce the requirement for standardisation by laboratory-specific conversion factors. DPCR is an appealing technology for quantitative detection of specific mutations with simultaneous measurement of the reference gene and is particularly suitable for minimal residual disease (MRD) diagnostics in chronic myeloid leukaemia (CML). However, a limitation of the dPCR assays compared to standard quantitative PCR (qPCR) is the background (termed lower limit of blank, LoB) of 1 or 2 positive droplets for BCR-ABL (Franke *et al.*, ASH 2015, Cross *et al.*, Leukemia 2016). The resulting false positive rate (FPR) limits the sensitivity and the ability to detect deep molecular remissions. This has hindered the definition of the lower limit of detection (LoD). We report here on the LoB and and the LoD of a newly developed assay.
Aims: Determination of LoB, LoD, linearity and precision of an optimized BCR-ABL digital PCR assay.
Methods: The assay was developed by Bio-Rad laboratories and consisted of a reverse transcriptase reaction followed by a duplex PCR detecting ABL and both the b2/a2 and b3/a2 transcripts of BCR-ABL. Digital droplet PCR was performed using the Bio-Rad QX200 system.
LoB and cross-hybridisation were assessed in non-template controls (NTC), BCR-ABL negative cell lines and healthy wild-type donor samples. LoD, precision and linearity were measured in serial dilutions of patient's cDNA in healthy donor's cDNA to simulate MMR, MR^4, $MR^{4.5}$, MR^5 and $MR^{5.5}$. Finally, the assay was tested on a certified CAP $MR^{4.7}$ sample.
Results: The specificity was >95% for both BCR-ABL and ABL in NTC and wild type samples. Extensive NTC analysis yielded no false positives for BCR-ABL PCR (n=0/176; LoB=0) and 1% false positives in ABL PCR (n=2/176; 1-2 positive droplets, LoB=0). The BCR-ABL assays of healthy donors were positive in 2% (n=5/234) with 1 positive droplet/positive sample. For 2 wells analysis, the detection rate for BCR-ABL for $MR^{4.5}$ and MR^5 was 100 and 88%, resulting in a LoD between 6 and 3 BCR-ABL copies/2 wells. Although the ABL copy number was only 200000 for 2 wells, the $MR^{5.5}$detection rate was 42%. However, in a merged 4 wells analysis, the detection rate was 100% for MR5 and 67% for $MR^{5.5}$ with an average of 6 and 2 BCR-ABL copies/4 wells (see Table 1). The $MR^{4.7}$sample was analyzed repeatedly, with 59 of 60 replicates evaluable. A total of 89 BCR-ABL copies (1.51/replicate) and 4,329,846 ABL copies (73387/replicate) were detected, resulting in a ratio of 0.0021 ($MR^{4.69}$). The false negative rate was below 3% when combining any pair of replicates, indicating an LoD of $MR^{4.7}$ for assays carried out in duplicate.

Table 1.

	2-well Analysis			4 well analysis		
Theoretical value	BCR-ABL Copies	ABL Copies	Detection rate	BCR-ABL Copies	ABL Copies	Detection rate
MR3	285	200750	24/24 (100%)	571	401500	12/12 (100%)
MR4	26	200375	24/24 (100%)	52	400750	12/12 (100%)
MR4.5	6	198992	24/24 (100%)	11	397983	12/12 (100%)
MR5	3	200558	21/24 (88%)	6	401117	12/12 (100%)
MR5.5	1	199350	10/24 (42%)	2	398700	8/12 (67%)

Summary/Conclusions: We report here on an optimized digital PCR assay with a LoB of zero and a LoD of 3 copies/2 wells. This highly sensitive and specific assay allows accurate detection of MRD in BCR-ABL positive diseases with a detection rate of 100% for MR5 and 67% for MR5.5 in a 4 wells analysis.

P262

VALIDATION OF THE EUTOS LONG TERM SURVIVAL SCORE IN DUTCH CML-PATIENTS

I. Geelen[1,*], N. Thielen[2,3], J. Janssen[2], M. Hoogendoorn[4], O. Visser[5], J. Cornelissen[6], P. Westerweel[1]
[1]Albert Schweitzer Hospital, Dordrecht, [2]Department of Hematology, VU Med-

ical Center, Amsterdam, [3]Diakonessenhuis, Utrecht, [4]Department of Hematology, Medical Center Leeuwarden, Leeuwarden, [5]Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [6]Department of Hematology, Erasmus Medical Center, Rotterdam, Netherlands

Background: Risk scores in chronic myeloid leukemia (CML) use baseline characteristics of CML patients in chronic phase to predict outcome and can be used to make decisions regarding first line TKI choice and monitoring frequencies. Until recently, risk stratification of CML patients was used based on scores developed in the pre-imatinib era (Sokal and Hasford risk score) with overall survival as the end point of interest. After the introduction of imatinib, the EUTOS score was established to predict the chance of achieving CCyR at 18 months, as a proxy for survival. However, since the major causes of death of CML patients are no longer CML-related, the need for baseline risk prediction has shifted from overall survival towards disease specific mortality. Therefore, recently the EUTOS long-term survival (ELTS) score was introduced to predict the risk of dying of CML in patients treated with first line imatinib.
Aims: The primary objective of this study was to perform a validation of the ELTS score in an independent cohort of "real-world" population-based CML patients.
Methods: Data from chronic phase CML patients were derived from the PHAROS-CML population based registry and Hemobase. Patients were stratified into a low, intermediate and high risk group according to the ELTS score. Data on "death due to CML" were provided by the Netherlands comprehensive cancer organization (IKNL) in combination with details from the patient records and a competing risk analysis was performed, to take death due to other causes into account.
Results: In total 349 patients were eligible for analysis; 273 patients (78%) were treated with first line imatinib and 76 patients (22%) were treated with a first line second generation TKI (2GTKI). Sokal, Hasford and EUTOS risk scores all did not predict differences in risk of "death due to CML". The ELTS score identified 163 patients as low risk (47%), 127 patients as intermediate risk (36%) and 59 patients as high risk (17%) at diagnosis. The 5 year cumulative incidence of "death due to CML" was indeed significantly higher in the high risk group (11%) compared to both the intermediate risk group (2%, p=0.02) and the low risk group (1%, p=<0.001). Between the intermediate and low risk group no statistically significant difference in risk of dying from CML was observed. A subgroup analysis of only imatinib treated patients showed similar results.
Summary/Conclusions: In the current study based on a "real-world" population-based CML patient cohort, we were able to validate the predictive value of ELTS high risk stratification for "death due to CML" in the current TKI era. Therefore, the ELTS score should be preferred over Sokal, Hasford and EUTOS scores in clinical practice.

Background: A second-generation tyrosine kinase inhibitor (TKI), dasatinib, is more potent in inhibiting BCR-ABLkinase activity than imatinib. We had previously reported an interim analysis of 63 patients with CML-CP who had discontinued dasatinib treatment after maintaining a deep molecular response (DMR) for more than a year (Lancet Haematology, 2015; 2 (12):e528-35) and demonstrated that dasatinib could be safely discontinued in patients with a DMR of at least 12 months. However, longer follow-up results would clinically be more critical in the treatment of CML.
Aims: In this trial, the total follow-up duration was set as 36 months after the discontinuation. The aim of the current follow-up study was to investigate whether those patients were able to discontinue dasatinib treatment for a longer follow-up period without relapse.
Methods: The eligibility criteria for pre-registration included CML-CP patients, 15 years or older, receiving dasatinib treatment as the second-line or subsequent therapy after imatinib. All participants gave written informed consent.
In this trial, DMR was defined as "no detectable BCR-ABL1 transcript determined using the international scale-based RQ-PCR at a single central laboratory (BML Inc., Tokyo, Japan; the cutoff corresponded to BCR-ABL1 0.0069% IS or molecular response (MR) 4.0)." Patients who showed a sustained DMR for 1 year (1-year consolidation phase) were subsequently included in the dasatinib-discontinuation stage. RQ-PCR was performed monthly for the first 12 months, and then every 3 months for the second year, and every 6 months for the third year, after discontinuing dasatinib. Relapse was defined as any positivity of BCR-ABL1 transcript by RQ-PCR even at one analysis point. In the present study, we assessed the estimated overall treatment-free remission (TFR) after discontinuing dasatinib, with 3 years of follow-up.
In addition, we also evaluated the impact of immunological profiles, including the cell counts of T and NK cell subsets in the peripheral blood throughout the 1-year consolidation phase, on TFR.
Results: Sixty-three patients were included in the dasatinib-discontinuation stage. The median follow-up was 44.0 months (IQR 40.5–48.0). After the 1-year-data cutoff, two additional molecular relapses were detected at 18 and 21 months after dasatinib discontinuation. After molecular relapse, 1 patient showed fluctuating BCR-ABL1 transcript values below MR 4.0 without restarting dasatinib therapy. A total of 35 out of 63 patients showed molecular relapse. No patient showed disease progression. The estimated overall TFR rate was 44.4% (95% confidence interval [CI], 32.0-56.2) at 36 months. A high count of two NK-cell phenotypes (CD3-CD56+ cells ≥539 cells/μl and CD16+CD56+ cells ≥506 cells/μl) and a low count of gd+ T-cells (<120 cells/μl) were detected to be significant factors affecting molecular relapse in the interim analysis; these showed sustained significance as predictors of a favorable TFR (P=0.0475, 0.0202, and 0.0093, respectively).
Summary/Conclusions: As the overall provability of TFR was relatively stable even for a longer follow-up period, our findings provided more compelling evidence supporting dasatinib discontinuation after a DMR for more than 1 year; this is feasible especially in patients with imatinib intolerance. We also reconfirmed that the counts of NK cells and functionally specific T-cells in the peripheral blood during dasatinib treatment might affect the TFR following dasatinib discontinuation.

ACUTE MYELOID LEUKEMIA ALTERS THE PERMEABILITY OF THE BONE MARROW VASCULAR MICROENVIRONMENT, FOSTERING DISEASE PROGRESSION AND DRUG RESISTANCE

D. Passaro[1,*], A. Di Tullio[1], A. Abarrategi[1], K. Rouault-Pierre[1], K. Foster[1], L. Ariza-McNaughton[1], P. Chakravarty[2], L. Bhaw[3], G. Diana[4], F. Lassailly[5], J. Gribben[6], D. Bonnet[7]
[1]Hematopoietic Stem Cell Laboratory, [2]Bioinformatics Unit, [3]Advanced Sequencing Unit, The Francis Crick Institute, [4]MRC Centre for Developmental Neurobiology, King's College, [5]Hematopoietic Stem Cell Lab, The Francis Crick Institute, [6]Department of Haemato-Oncology, Barts Cancer Institute - Queen Mary University of London, [7]Haematopoietic Stem Cell Laboratory , The Francis Crick Institute, London, United Kingdom

Background: The biological and clinical behavior of hematological malignancies is not only determined by the properties of the leukemic cells themselves, but it is also highly affected by the interaction with the microenvironment, pointing to the existence of an active crosstalk between the two compartments. Previous studies showed that acute myeloid leukemia (AML) actively modify endothelial cells *ex vivo* via several pathways, mainly mediated by VEGF. However, anti-VEGF therapies haven't produced successful results in clinical trials.
Aims: Our aim is to perform an extensive study of the vascular niche in the bone marrow (BM) of AML xenografts to provide a global picture of the vasculature in AML disease and design new therapeutic strategies.
Methods: We combined the use of mouse models of AML, human AML derived xenografts (PDX) and direct analysis of patients derived samples to study the vascular niche in AML disease. We used two-photon confocal microscopy as a powerful tool to functionally image the BM vasculature *in vivo*. We used RNA-sequencing to study the AML-associated transcriptomic profile in vascular endothelial cells.
Results: We found several abnormalities in the vascular architecture and function in PDX, such as increased number of endothelial cells, increased microvascular density (MVD), loss of normal sinusoidal architecture and increased hypoxia. Moreover, vascular permeability was increased as measured via two-photon imaging. Interestingly, induction chemotherapy failed to normalize the vascular permeability in the BM, although it significantly reduced the AML engraftment. Via high-throughput transcriptomic analysis, we showed that AML-induced hypoxic environment altered the molecular signature of vascular endothelial cells, activating pro-angiogenic pathways and positively regulating the response to hypoxia. We identified increased nitric oxide (NO) as a major mediator of the AML-induced vascular leakiness in the BM. Notably, increased NO levels were found also in BM aspirates of patients at diagnosis compared to healthy donors, and failure in reducing NO levels after chemotherapy appeared to be associated with a higher incidence of unsuccessful treatment. Strikingly, inhibition of NO production in mouse models of AML and in AML-derived PDX reduced vascular permeability, preserved normal HSC function and significantly improved treatment response (Figure 1).

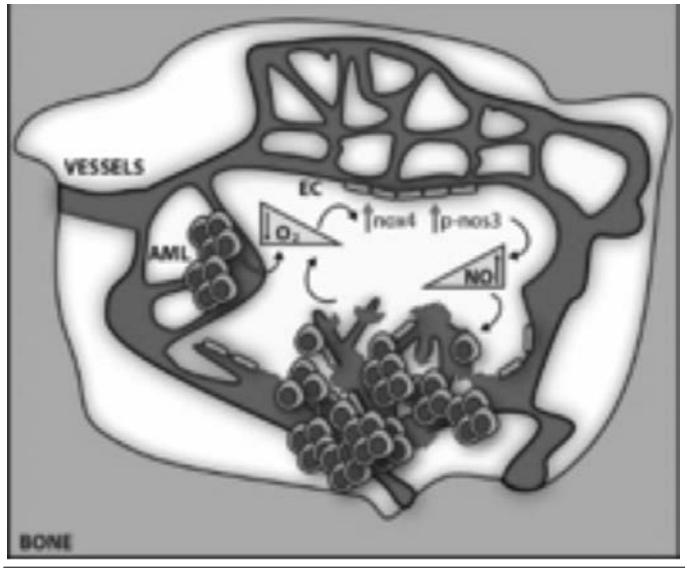

Figure 1.

Summary/Conclusions: We have shown an altered highly permeable vascular niche in the BM of AML PDX, mainly caused by increased NO production by the endothelial niche, contributing to disease progression and treatment failure. Our data call for clinical trials incorporating NOS inhibitors during the remission phase, to target the abnormal vascular niche and improve AML treatment response.

P265

BUILDING HUMAN BONE MARROW-LIKE MODELS TO STUDY NICHE INTERACTIONS

H.-J. Prins[1], T. Csikos[1], R. de Jong-Korlaar[1], R. Ruiter[1], S. van Veen[1], H. Yuan[2], J. de Bruijn[2], G. Ossenkoppele[1], R. Groen[1,*]
[1]Hematology, VU University Medical Center, Amsterdam, [2]Xpand Biotechnology BV, BIlthoven, Netherlands

Background: Previously, we have reported that our human bone marrow-like scaffold (huBM-sc) xenograft model allows the engraftment and outgrowth of normal and malignant hematopoiesis (*e.g.* multiple myeloma (MM) and acute lymphoblastic leukemia (ALL) (Groen *et al.* Blood 2012; Gutierrez *et al.* JCI 2014) and more recently acute myeloid leukemia (AML; Antonelli *et al.* Blood 2016). These studies show that i) engraftment is not correlated with prognostic risk-groups, ii) there is preferential outgrowth in humanized scaffolds compared to the murine BM, iii) the huBM-sc environment results in better maintenance of self-renewal potential and less clonal drift of the leukemic cells. Although the presence of human osteoblasts and bone mimics a human BM niche more closely than the murine BM in standard xenotransplant models (*e.g.* NOD-SCID/NSG mice), still some essential components of the human BM niche, *i.e.* human blood vessels, are missing.
Aims: To implement human vasculature in the huBM-sc xenograft model in order to create a multi-tissue compartment that "maximally humanizes" the BM-like niche of our scaffolds.
Methods: Towards successful implementation of a human vascular system we compared: i) scaffold material composition (biphasic calcium phosphate (BCP) *vs* tricalcium phosphate (TCP)); ii) scaffold shape (particles *vs* tubes); iii) different types of matrigel for cord blood-derived endothelial progenitor cells (CB-EPCs) embedding.
Results: Histological analysis of these fully humanized scaffolds showed a large number of functional human CD31-positive blood vessels, and additional CD44, CD146, LEPR and nestin-positive stromal niche cells. Comparison of the composition and the shapes of the scaffolds indicated superiority of TCP and tube-shaped scaffolds in supporting the formation of vessels. Engraftment of BM-derived CD34+ cells in the CB-EPC embedded huBM-sc resulted in increased multilineage hematopoietic engraftment, as compared to huBM-sc without CB-EPCs. Moreover, we observed that incorporation of CB-EPCs provides faster kinetics of engraftment of both patient-derived MM and AML cells, and proved to be essential for the engraftment of blast cells from myelofibrosis patients.
Summary/Conclusions: Thus, with the addition of human CB-EPCs and BM stromal cells, our scaffold systems now simulate both endosteal and vascular niches of the BM, thereby more closely recapitulating the human hematopoietic microenvironment.

P266

MULTISCALE IMAGE-BASED QUANTITATIVE ANALYSIS OF BONE MARROW STROMAL NETWORK TOPOLOGY REVEALS STRICT SPATIAL CONSTRAINTS FOR HEMATOPOIETIC-STROMAL CELLULAR INTERACTIONS

Á. Gomáriz[1], P. Helbling[1], S. Isringhausen[1], U. Suessbier[1], A. Becker[2], A. Boss[3], T. Nagasawa[4], G. Paul[5], O. Göksel[5], G. Zkékely[5], S. Stoma[6], S. Nørrelykke[6], M. Manz[1], C. Nombela Arrieta[1,*]
[1]Hematology, University and Universit Hospital Zurich, [2]Radiology, University Hospital Zurich, [3]Radiology, University Hospital Zurich, Zurich, Switzerland, [4]Frontier Biosciences, Osaka University, Osaka, Japan, [5]Computer Vision, [6]SCOPE M, ETH, Zurich, Switzerland

Background: Adult bone marrow (BM) cavities host continuous, demand adapted and high throughput blood cell production, which is maintained by a rare population of self-renewing, multipotent hematopoietic stem cells (HSCs). Aside from its diverse hematopoietic content, the BM is populated by a heterogeneous fraction of mesenchymal, endothelial and neural stromal cells, which provide the necessary tissue infrastructure for hematopoiesis to unfold while playing fundamental regulatory roles in hematopoietic development. Recent evidence suggests that tissue regions around BM venous microvessels (termed sinusoids), which are enriched for mesenchymal CXCL12-abundant reticular cells (CARc), serve as the principal regulatory niches for HSCs as well as other hematopoietic progenitor populations. Despite this proposed role as putative specific niche-restricted components, comprehensive data on the frequency, global spatial distribution and topology of sinusoidal endothelial and CAR cell networks is largely lacking to date.
Aims: The principal aim of our work is to employ state of the art imaging techniques to perform a detailed 3D quantitative and structural analysis of the BM stromal infrastructure, with a special focus on sinusoidal microvasculature and the CAR cell mesenchymal component, both of which are essential regulators of HSC maintenance.

Methods: We have developed i) advanced microscopy techniques allowing multiscale 3D visualization of entire bone marrow cavities with cellular and subcellular detail ii) customized computational tools enabling the detection and quantification of discrete cell subsets/structures in 3D images of the BM in an unbiased fashion, as well as a rigorous spatial statistical analysis of cellular interactions.
Results: Using 3D-quantitative microscopy (3D-QM) we uncover that BM stromal cells are in fact 15-20 fold more abundant than previously reported. The massive underestimation of these relevant cell subsets results from the highly inefficient isolation of these cellular types with currently employed flow cytometry protocols. Our image-based analyses further reveals that sinusoidal and CAR cell stromal networks occupy a disproportionately large fraction of the BM space, consequently constraining the tissue volume available for hematopoietic cell distribution. In fact, the vast majority of BM resident hematopoietic cells are unavoidably in direct contact with the CAR cellular projections and in close proximity (<25µm) to the extraluminal surface of sinusoidal endothelium.
Summary/Conclusions: Collectively, our quantitative description of stromal microarchitecture, challenges current models of cell type-specific niche interactions in the BM, which are based in largely inaccurate estimations of cell frequency and spatial confinement of stromal cells in this organ.

P267

TEMPLATED V(D)J INSERTIONS ARE A NOVEL BIOLOGIC MECHANISM FOR B-CELL RECEPTOR REPERTOIRE DIVERSIFICATION

M.T. Koning[1,*], I. Trollmann[1], R. Rademaker[2], R. Toes[3], H. Veelken[1]
[1]Department of Hematology, Leiden University Medical Center, Leiden, [2]GenMab, Utrecht, [3]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands

Background: Recently, large LAIR1 insertions at the V-D junction were described as a novel mechanism to generate antibodies against *P. falciparum* RIFIN antigens on infected erythrocytes (Tan *et al.*, Nature 2016). These templated insertions potentially add a novel biological mechanism used by the immune system to generate B-cell receptor repertoire diversity.
Aims: We investigated whether templated insertions occur in the B-cell repertoire of healthy donors and whether such insertions could be functionally expressed to explore their biological function.
Methods: We obtained >52,000 unique full-length VDJ sequences of IgM, IgG, IgA, and IgE isotypes by unbiased ARTISAN PCR (Koning *et al.*, BJH 2016) from 6 healthy donors. Abnormally long sequences and junctions were searched for templated insertions by BLAST. Identified VDJ carrying templated insertions were co-expressed with a panel of 172 light chains on multiple myeloma cell lines and assessed for surface expression of transgenic immunoglobulin. The VDJ described by Tan *et al.* were included as controls.
Results: Six unique VDJ sequences, all from the same donor, carried a templated insertion in-frame ($E=10^{-37}$ – 0). These sequences represented all VDJ sequences with a CDR3 region >150 bp. Exonic sequences from RPLP0, ZNF316, and an inverted IGHV-IGHD sequence were identified as insertions in unmutated IgM VDJ transcripts. The LAIR1 exon described by Tan *et al.* and an intergenic region adjacent to IGHD3-22 were identified as insertions in IgG VDJ transcripts. One IgA VDJ contained two intergenic sequences positioned closely together on chromosome 22. Somatic hypermutation burden correlated strongly between the the IGHV segment and the templated insertions ($r=0.9944$; $p<0.001$). All templated insertions harboured cryptic RSS sites at their termini. All three IgM VDJ carrying templated insertions and the IgG rearrangement with the IGHD locus templated insertion gave rise to detectable surface immunoglobulin after coexpression with at least one light chain in the panel. The IgG VDJ carrying the LAIR1 templated insertion produced no detectable surface immunoglobulin. In contrast, the VDJ sequences carrying LAIR1 templated insertions as described by Tan *et al.* could be expressed with the majority of the light chains. The IgA rearrangement remains to be tested in this system.
Summary/Conclusions: Templated insertions represent a novel antibody diversification mechanism. Their presence in naïve B-cells, their exclusive positioning in VDJ junctions, and the universal presence of cryptic RSS sites point to primary VDJ recombination or secondary V gene editing as the generating mechanism. Certain loci (*e.g.* LAIR1) and certain individuals appear to have increased susceptibility. The available data suggest RAG to be involved in these insertions. We propose that templated insertions represent inserted signal sequences from aberrantly rearranged chromosomal sequences with cryptic RSS sites.

P268

TARGETING THE CASPASE / NOX2 AXIS TO MODULATE MACROPHAGE POLARIZATION

S. Solier[1,*], L. Meziani[2], M. Mondini[2], C. Lacout[1], P. M.-C. Dang[3], J.-C. Martinou[4], P. Vandenabeele[5], E. Deutsch[2], O. Hermine[6], N. Droin[1], C. Dupuy[7], J. El-Benna[3], E. Solary[1]
[1]INSERM UMR1170, [2]INSERM UMR1030, Gustave Roussy, VILLEJUIF, [3]INSERM UMR773, Université Paris 7 Denis Diderot, Paris, France, [4]Department of Cell Biology, University of Geneva, Genève, Switzerland, [5]Molecular and Cell Death Unit, VIB, Inflammation Research Center, Ghent, Belgium, [6]Clinical Hematology Department, Faculty of Medicine and AP-HP Necker-Enfants Malades, Paris, [7]CNRS UMR8200, Gustave Roussy, VILLEJUIF, France

Background: Caspases, which are key effectors of apoptosis, have demonstrated non-apoptotic functions. One of these functions is the differentiation into macrophages of peripheral blood monocytes exposed to Colony-Stimulating Factor-1 (CSF1). Conversely, GM-CSF induces the differentiation of monocytes into macrophages in a caspase-independent manner. Macrophages generated by CSF1 and GM-CSF have distinct polarity.
Aims: Macrophage polarization plays an important role in the pathogenesis of diverse human diseases as cancer, leading us to explore if caspase inhibition would affect macrophage polarization.
Methods: To explore the role of caspases in CSF1 differentiation, we used human monocytes sorted from buffy coats or from blood of NOX2-deficient patients treated by cytokines, and we generated monocyte-restricted caspase-8 knockout and caspase-3/caspases-7 double knockout mice, which were treated with bleomycin to induce pulmonary fibrosis.
Results: Caspase activation is involved in the generation of M2 polarized macrophages. Caspase inhibition delays the *ex vivo* differentiation of peripheral blood monocytes exposed to CSF1 and modifies the phenotype of generated macrophages, *e.g.* cell shape, surface markers and cytokine secretion. In mice, caspase knock-out also modified the phenotype of monocytes induced to differentiate into macrophages. Caspase activation appeared to be prominent at the mitochondria level and responsible for the NOX2-dependent generation of cytosolic radical oxygen species (ROS). Activation of the NOX2 complex is associated with p47phox cleavage by caspases. Mice treated with bleomycin typically develop a pulmonary fibrosis. Bleomycin-induced lung fibrosis was delayed in monocyte-restricted caspase-8 knockout mice and prevented by treatment with a caspase inhibitory molecule, including zVAD-fmk and the clinically developed IDN6556. This effect was associated with a change in the polarization of lung-infiltrating macrophages.
Summary/Conclusions: Caspase inhibition in monocytes prevent the development of bleomycin-induced lung fibrosis by modifying macrophage polarization, suggesting that caspase inhibitory molecules may be an exciting therapeutic strategy to modulate macrophage polarization with diverse applications including cancer treatment.

MULTIPLE MYELOMA-POLARIZED M2C MACROPHAGES PROMOTE A TUMOR-SUPPORTIVE OSTEOLYTIC MICROENVIRONMENT VIA CXCL13

K. Beider[1,*], V. Voevoda[1], H. Bitner[1], E. Rosenberg[1], H. Magen[2], O. Ostrovsky[1], E. Ribakovsky[1], A. Shimoni[1], L. Weiss[3], M. Abraham[3], A. Peled[3], A. Nagler[1]
[1]Hematology Division, Bone Marrow Transplantation, SHEBA MEDICAL CENTER, Ramat-Gan, [2]Institute of Hematology, Davidoff Cancer Center, Rabin Medical Center, Petach-Tikva, [3]Institute of Gene Therapy, Hadassah Hebrew University Hospital, Jerusalem, Israel

Background: Previous studies including our work revealed a role of MM-educated M2-like macrophages (MΦ) in MM survival and drug resistance. However, the mechanism by which neoplastic plasma cells shape BM microenvironment and affect MΦ polarization is still poorly defined.
Aims: To investigate tumor-promoting changes in the myeloid compartment of the BM niche that are initiated by MM cells.
Methods: We utilized our *in vivo* xenograft model of BM-disseminated human myeloma. The CRISPR/Cas9 technology was used to knockdown CXCL13 expression in MM cell lines.
Results: BM analysis of mice inoculated with human CXCR4-expressing RPMI8226 cells revealed a significant increase in M2 MΦ in comparison to non-injected controls ($p<0.01$). Characterization of MM-associated changes in the BM milieu revealed murine chemoattractant CXCL13 being one of the most profoundly increased factors upon MM development. Elevated CXCL13 was also detected in blood of MM-bearing animals comparing to healthy controls. IHC staining identified myeloid cells as the main source of increased murine CXCL13 detected in MM-occupied BM. Murine BM CXCL13 mRNA expression strongly correlated with human β2-microgllobulin mRNA levels ($p<0.0001$ $R^2=0.64$), indicating the interrelation between tumor burden and CXCL13 induction. Reduction of MM load upon the treatment with anti-myeloma agents bortezomib and panobinostat resulted in corresponding correlated decrease in murine CXCL13, both in BM and blood, suggesting the possible utilization of CXCL13 levels as surrogate marker of anti-MM treatments response.
CXCL13 expression by MΦ is known to represent specific anti-inflammatory M2c phenotype acquisition. Indeed, we observed a significant up-regulation of additional M2c markers, such as MERTK and MRC1 in the BM occupied with MM in strong correlation with CXCL13 expression ($p<0.001$ $R^2=0.65$). In vitro studies confirmed the ability of MM cell lines (n=6) to induce CXCL13 and concurrent expression of M2c markers (MERTK, CD206, CD163) in co-cultured human monocytes and MΦ. Interaction with MΦ reciprocally induced CXCL13 expression in MM cell lines and primary human CD138+ cells. Mechanistically, TGFβ signaling was involved in CXCL13 induction in both MM cells and MΦ, as TGFβ receptor inhibitor SB431542 interfered with CXCL13 induction. Osteo-

clastogenic assays were used to elucidate the down-stream effects of the elevated CXCL13. Recombinant CXCL13 as well as medium produced by co-cultured MM-MΦ increased RANKL expression and induced TRAP+ osteoclast (OC) formation *in vitro*, while CXCL13 neutralization blocked these activities. We next abrogated CXCL13 expression in MM cell lines using the CRISPR/Cas9 technology. The loss of CXCL13 had no effect on MM *in vitro* growth or drug sensitivity. However, mice inoculated with CXCL13-silenced MM cells developed significantly weaker BM disease compared to mice receiving the non-manipulated cells. Reduced tumor load correlated with decreased numbers of M2c MΦ in BM, decreased bone disease, and lower expression of OC-associated genes. Finally, the presence of CXCL13 in primary MM samples was evaluated. Elevated levels of CXCL13 transcript and protein were detected in BM aspirates from MM patients (n=24) in comparison to normal BM (n=5) and were in correlation with gene expression signature associated with OC activation and M2c MΦ phenotype (Figure 1).

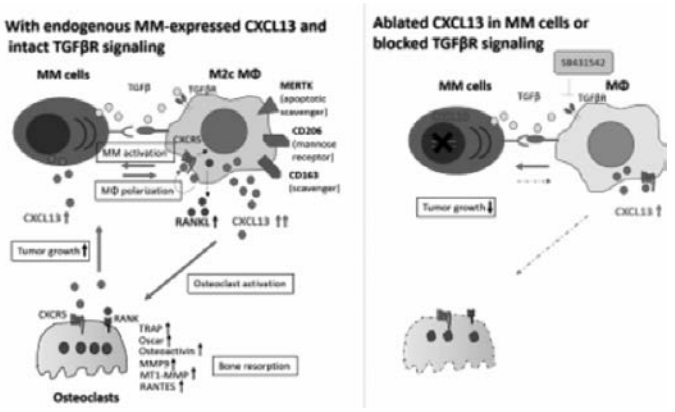

Figure 1.

Summary/Conclusions: Our findings suggest that bidirectional interactions of MΦ with MM tumor cells result in M2c MΦ polarization, CXCL13 induction and subsequent OC activation, enhancing their ability to support bone resorption and MM progression. CXCL13 may thus serve as potential novel target for the diagnosis and treatment of MM.

P270

RE-ORDERING THE B CELL DEVELOPMENT HIERARCHY IN HUMAN FETAL BONE MARROW: CHARACTERISATION OF A NOVEL HUMAN FETAL B PROGENITOR

S. O'Byrne[1,*], N. Elliott[1], G. Buck[1], B. Liu[1], B. Povinelli [2], N. Fordham[2], E. Louka[2], K. Bartolovic[2], A. Karadimitris[3], A. Mead[2], I. Roberts[12], A. Roy[1]
[1]Paediatrics, University of Oxford, [2]MHU, Weatherall Institute of Molecular Medicine, Oxford, [3]Centre for Haematology, Imperial College London, London, United Kingdom

Background: The cellular hierarchy of normal human fetal B-lymphopoiesis remains poorly defined. We have previously identified a novel population of PreProB progenitors (CD34+CD19+CD10-) in fetal liver (FL)[1] that is further expanded in fetal bone marrow (FBM)[2], and co-exists with adult-type CD34+CD19+CD10+ ProB progenitors. Increasing evidence indicates that infant ALL and many cases of childhood ALL arise in fetal life, suggesting that ontogeny-related changes in B-cell development may be important for *in utero* leukaemia initiation. Therefore, understanding the human fetal B cell hierarchy, especially the differences between PreProB and ProB progenitors may be key to understanding the origins of infant and childhood leukaemia.
Aims: To determine B cell developmental pathways in human second trimester FBM, with a view to establishing the fetal B cell hierarchy.
Methods: The characteristics of the haematopoietic stem cell (HSC), lymphomyeloid multipotent progenitor (LMPP), early lymphoid progenitor (ELP) and committed B-progenitor compartments of FBM samples were analysed by multiparameter flow cytometry, differentiation and clonogenic assays, transcriptome analysis and single cell RQ-PCR.
Results: All stages of B cell development were demonstrable in human FBM up to transitional B cells with a rapid expansion of B progenitor numbers from the LMPP stage. FBM HSC, progenitors (MPP, LMPP, ELP, PreProB and ProB-progenitors) and B-cells were FACS-sorted for functional/ molecular assays. *Functional assays*: B cell differentiation assays demonstrated expected multilineage output from HSC, MPP and LMPP, but a pure B cell output from PreProB and ProB progenitors. While PreProB progenitors gave rise to ProB progenitor cells *in vitro*, the converse was not true; thereby placing PreProB upstream of ProB in the B cell hierarchy. Myeloid colony assays gave expected multilineage output from HSC/MPP; and GM colonies from LMPP; while ELP, PreProB and ProB progenitors generated no colonies, confirming their lymphoid commitment. *Transcriptome analysis and single cell RQ-PCR*: Fetal HSPC populations were flow sorted and analysed by RNASeq of bulk populations as well as single cell RQ-PCR using a customised 96-gene panel. Stem cell populations (HSC, MPP and LMPP) showed good spatial segregation from lymphoid progenitors (ELP, PreProB and ProB) by principal component analysis both at bulk and single cell level. Single cell analysis demonstrated a differentiation trajectory from HSC to mature B cells with PreProB progenitors clustering between LMPP and ProB. There was sequential upregulation of B lymphoid specific genes from HSC to ProB progenitors and the level of expression was always lower in PreProB compared to ProB, suggesting they are upstream of ProB. PreProB progenitors demonstrated a distinct gene expression profile compared to ProB progenitors. 739 genes were significantly differentially expressed (FDR<0.1) between these two populations with 538 of these being upregulated in PreProB, including some myeloid and leukaemia-associated genes. Genes overexpressed in ProB included B cell specific genes.
Summary/Conclusions: Detailed immunophenotypic, functional and molecular studies allow us to propose a human fetal B cell developmental hierarchy for the first time in which the unique PreProB progenitors are distinct from and lie upstream of the ProB progenitors. These results may have important implications in understanding the pathogenesis of infant and childhood leukaemias.

HUNDREDS OF EMBRYONIC HEMATOPOIETIC PRECURSORS CONTRIBUTE TO LIFE-LONG HEMATOPOIESIS

M. Ganuza Fernandez[1,*], T. Hall[1], D. Finkelstein[2], A. Chabot[1], G. Kang[3], S. McKinney-Freeman[1]
[1]Experimental Hematology, [2]Department of Computational Biology, [3]Department of Biostatistics, St. Jude Children's Research Hospital, Memphis, United States

Background: Prior studies of the frequency of emerging hematopoietic stem cells (HSCs) and their precursors during mammalian ontogeny have all required embryo disruption, transplantation assays and concluded that very few HSC emerge from endothelial precursors during embryogenesis to establish life-long hematopoiesis. An alternative approach independent of embryo disruption or transplantation would more accurately reflect the true dynamics of HSC emergence during mammalian development.
Aims: To determine the frequency of emerging HSCs and their precursors throughout mammalian ontogeny.
Methods: Here, we employed the *Confetti* allele, in which a cassette targeted to the *ROSA26* locus randomly and permanently marks cellular progeny with GFP, YFP, RFP or CFP when exposed to *Cre recombinase*. We determined empirically that sample-to-sample variance in the distribution of *Confetti* colors in the blood of the following adult mice inversely correlated with the number of hematopoietic precursors specified during the indicated window of *Cre recombinase* activity: *ROSA26(Confetti/+) Flk1(+/*Cre*)* (mesodermal precursors, E7), *ROSA26(Confetti/+) VE-cadherin(+/*Cre*)* (mid-gestation endothelial precursors, E8.5-E10.5), and *ROSA26(Confetti/+) Vav1(+/*Cre*)* (hematopoietic progenitors E11.5-E14.5). This correlation was used to estimate the number of hematopoietic precursors emerging during each stage of development.
Results: An inverse correlation of sample-to-sample variance in the distribution of *Confetti* colors and numbers of labeled initiating events was established *in vitro* by plating limiting dilution replicates of immortalized *Confetti+* fibroblasts and assessing the resulting sample-to-sample *Confetti* variance of each cell dose plated. We thus derived a linear formula to estimate numbers of initiating events using the sample-to-sample Confetti color variance in a particular tissue (*e.g.* peripheral blood (PB)). We tested this formula *in vivo* via limiting dilution transplantation with *Confetti+* bone marrow. Classic limiting dilution analysis of transplanted mice revealed about 1/12,000 repopulating units in the transplanted BM. The sample-to-sample variance in the distribution of *Confetti* colors in the PB of recipients yielded a similar estimate of the frequency of repopulating events, validating our empirically-derived formula. We further validated our approach *in vivo* by calculating 222 repopulating units in transplant recipients of dissociated cultured E11.5 aorta-gonad-mesonephros (AGMs) explants. This finding correlates very well with previous reports that E11.5 cultured AGM explants contain about 150 transplantable HSCs. Analyses of the sample-to-sample variance of the *Confetti* colors in the blood of cohorts of *ROSA26(Confetti/+) Flk1(+/*Cre*)*, *ROSA26(Confetti/+) VE-cadherin(+/*Cre*)* and *ROSA26 (Confetti/+) Vav1(+/*Cre*)* mice revealed that about 719 mesodermal precursors, 633 endothelial precursors and 545 fetal liver hematopoietic precursors contribute to the emerging hematopoietic system. Our findings are in sharp contrast to previous reports that very few precursors and emerging hematopoietic progenitors establish the hematopoietic system. Our data further suggest that a "developmental bottleneck" exists after the fetal liver stage of hematopoietic ontogeny that restricts the numbers of precursors that ultimately contribute to life-long hematopoiesis.
Summary/Conclusions: We report here a novel approach to examine the complexity of the emerging hematopoietic system without perturbing the developing embryo. This represents a new platform to identify biologically relevant processes that govern the dynamics of different populations during embryonic

development. We thereby report for the first time that the clonal origin of blood is much more complex than previously thought, with hundreds of precursors contributing to the establishment of the mammalian blood system at multiple stages of ontogeny.

A20 RESTRAINS THYMIC REGULATORY T CELL DEVELOPMENT

T. Haas[1,*], J.C. Fischer[1], V. Otten[1], S. Spoerl[1], H. Poeck[1]
[1]Klinik und Poliklinik für Innere Medizin III, Klinikum rechts der Isar, TU München, München, Germany

Background: Maintaining immune tolerance requires the production of Foxp3 expressing T regulatory (Treg) cells in the thymus. Activation of NF-κB transcription factors is critically required for Treg cell development, partly via initiating Foxp3 expression. NF-κB activation is controlled by a negative feedback regulation through the ubiquitin editing enzyme A20, which reduces pro-inflammatory signaling in myeloid cells and B cells. In naive $CD4^+$ T cells, A20 prevents necroptosis and promotes inflammation.
Aims: This study is aimed at analyzing the role of the NF-κB regulator A20 in Treg cell development and function.
Methods: We used $A20^{F/F}$ CD4Cre mice, which specifically lack A20 in T cells, to analyze the Treg cell compartment *in vivo.* We characterized expansion and differentiation of A20-deficient Treg cells *in vitro*. We performed competitive bone marrow engraftment between WT and A20-deficient bonemarrow *in vivo* to analyze whether one bone marrow compartment would outperform another or would favor development of certain T cell or other immune cell subsets. We performed alloegeneic hematopoietic stem cell transplantation with WT BM+T cells ± WT *vs* A20-deficient Treg cells to analyze whether A20-deficient T reg cells would reduce GVHD to the same extent as WT Treg cells.
Results: Using mice deficient for A20 in T lineage cells, we show that thymic and peripheral Treg cell compartments are quantitatively enlarged due to a cell-intrinsic developmental advantage of A20-deficient Treg cells. $A20^{-/-}$ Treg cells efficiently suppressed effector T cell mediated graft-*versus*-host disease after allogeneic hematopoietic stem cell transplantation, demonstrating normal suppressive functionality. Holding thymic production of natural Treg cells in check, A20 thus integrates reduced regulatory T cell activity and increased effector T cell survival into an efficient $CD4^+$ T cell response.
Summary/Conclusions: In light of the largely anti-inflammatory effects that have been attributed to A20 in many cell types, this proinflammatory aspect of A20 physiology in effector and regulatory $CD4^+$ T cells is particularly important since it may contribute to a change of perception of the functions of A20 as a negative regulator of NF-κB in the context of inflammation. Whether targeted modulation of A20 activity allows the induction of Treg cell mediated immune tolerance or, alternatively, boosting of favorable T cell immunity is a question of translational relevance that needs to be addressed in the future. .

P273

THE TRANSCRIPTION FACTOR C/EBPG REGULATES MAST CELL DEVELOPMENT AND FUNCTION

M. Kardosova[1,*], L. Potuckova[2], I. Halova[2], P. Zjablovskaja[1], L. Draberova[2], P. Draber[2], M. Alberich-Jorda[1]
[1]Hematooncology, [2]Laboratory of Signal Transduction, Institute of Molecular Genetics, Academy of Sciences of the Czech Republic, Prague, Czech Republic

Background: Mast cells are key effector cells involved in protection against infection and allergic responses. Defects in mast cells are related to immunological disorders, and therefore it is critical to fully understand the transcriptional network that controls their generation and activity. Differentiation of progenitors to mature mast cells is promoted by several transcription factors, such as GATA1, GATA2, STAT5, and MITF, and requires downregulation of C/EBPα. Recently, we identified another member of the C/EBP family of transcription factors, C/EBPγ, as a direct C/EBPα target gene. However, the role of C/EBPγ in mast cells remains so far elusive.
Aims: In this study we aim to determine the role of the transcription factor C/EBPγ in mast cell development and function. Next, we investigate the mechanisms by which C/EBPγ is controlling these processes.
Methods: In order to determine the role of C/EBPγ in murine mast cells, we generated *Cebpg* conditional knockout mice, which allow excision of *Cebpg* in the hematopoietic system from the early embryogenesis. We employed $Cebpg^{flox/flox}$ Vav-1Cre- and $Cebpg^{flox/flox}$ Vav-1Cre$^+$ mice, referred here as WT and *Cebpg* KO, respectively. Excision of *Cebpg* was assessed by RT-PCR and western blot analysis in bone marrow and spleen cells. Using flow cytometry, we enumerated mast cell counts in the peritoneal cavity of healthy WT and *Cebpg* KO mice. To elucidate whether C/EBPγ plays role in mast cell response to bacterial infection, we challenged these mice intraperitoneally with lipopolysaccharide (LPS). Finally, we used intraperitoneal injection of distilled water to eradicate peritoneal mast cells and then monitored repopulation of peritoneum over time. To further explore the role of C/EBPg in mast cells *in vitro*, we established bone marrow derived mast cells (BMMCs) and determined their growth (cell numbers), morphology (toluidine blue staining), and transcription factors expression (RT-PCR) at different time points. Degranulation potential of BMMCs was specified by measuring the percentage of b-glucuronidase released to the supernatant upon anti-TNP IgE sensitization and TNP-BSA activation. To investigate the effects of absence of *Cebpg* during mast cell migration, we employed transwell migration assays.
Results: We verified efficient ablation of *Cebpg* on mRNA and protein level in bone marrow and spleen of *Cebpg* KO mice. Analysis of peritoneal cavity of WT and *Cebpg* KO mice showed similar frequency and numbers of mast cells in steady state conditions. However, *Cebpg* deficient mice exhibit increased number of peritoneal mast cells after LPS stimulation in comparison to WT control littermates. Surprisingly, mice lacking *Cebpg* presented defective peritoneal mast cell repopulation. Since mast cells are scarce and difficult to isolate from *in vivo* models, we employed BMMCs to investigate the effects of *Cebpg* ablation in mast cell development and function. We observed that bone marrow from *Cebpg* KO mice generated reduced number of BMMCs in comparison to WT controls. Functionally, we demonstrated that deletion of *Cebpg* reduced mast cell migration towards antigen, SCF or PGE, and impaired degranulation upon FcεRI-mediated activation. Further, BMMCs exhibit increased expression of C/EBPα in the absence of C/EBPγ.
Summary/Conclusions: In summary, we revealed C/EBPγ as important transcription factor which suppresses C/EBPα expression, thereby favoring mast cell development and function. Our data identifies a new component of the mast cell transcriptional network and provides a better understanding of mast cells in normal physiological conditions and disease.

P274

TRANSCRIPTIONAL DIVERSITY AND DEVELOPMENTAL POTENTIAL OF EARLY HEMATOPOIETIC PROGENITORS REVEALED BY CELLULAR BARCODING AND TRANSCRIPTOME-WIDE PROFILING

D. Tronik-Le Roux[1,*], A. Legrand[2], V. Michaels[2], J. Renard[1], S. Chalabi[3], R. Olaso[3], J.-F. Deleuze[3], C. Battail[3], S. Ezine[2]
[1]CEA, [2]INSERM, Paris, [3]CEA, Evry, France

Background: One of the main complications of anti-cancer therapies or bone marrow transplantation protocols is their deleterious effect on the blood system, leading to prolonged neutropenia and increased risk for infections. Manipulating hematopoietic stem cells differentiation pathways to favor production of specific lineage-committed progenitors might optimize blood recovery.
Aims: In this study we aimed 1) to determine and quantify the contribution of medullary progenitor populations (MPP) to the repopulation of the T cell pathway using the barcode cellular labelling strategy that we have previously developed and 2) to decipher the heterogeneity of these MPP at the transcriptional level.
Methods: Three different MPP subsets, of the following phenotype: VCAM1+Flt3 (MPP1); VCAM1-Flt3+ (MPP2) and VCAM-1Flt3+ILR7 (CLP), were tagged with different barcodes carried by a collection of lentivirus and transplanted in mice. Barcoded cells in recipient mice were analyzed by flow cytometry. For whole transcriptome strand-specific sequencing, three biological replicates, per cell population, were sequenced at high depth of coverage (2 x 120 million reads).
Results: The results allowed the *in vivo* dynamic tracking of the progeny of the barcoded progenitors in transplanted recipients. Moreover, transcriptome-wide profiling allowed to identify, by cluster analysis of RNAseq profiles together with gene ontology annotation, unique co-expressed markers for the prospective isolation of these populations. Unsupervised classification correctly classified reference surface markers, currently used to purify progenitors, which validate our bioinformatic methodology. Transcriptional regulation of these cell surface markers was further assess by searching for co-expressed transcription factors and enriched binding sites in their promoters. Their grouping enabled to establish undescribed regulatory networks, specific to each progenitor cell.
Summary/Conclusions: Collectively, the cellular barcoding tool and the molecular changes observed at RNA and functional levels as they occur *in vivo* in the context of physiologic commitment processes, highlighted data that contribute to a deeper understanding of the dynamic of T-lineage differentiation and the lineage restriction process.

Hodgkin lymphoma

P275

LONG-TERM OUTCOME OF PATIENTS WITH NODULAR LYMPHOCYTE-PREDOMINANT HODGKIN LYMPHOMA TREATED WITHIN THE RANDOMIZED HD7-HD15 TRIALS: AN ANALYSIS FROM THE GERMAN HODGKIN STUDY GROUP

D.A. Eichenauer[1,*], A. Plütschow[1], M. Fuchs[1], B. von Tresckow[1], V. Diehl[2], P. Borchmann[1], A. Engert[1]
[1]First Department of Internal Medicine, [2]German Hodgkin Study Group, University Hospital Cologne, Cologne, Germany

Background: Nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL) is a rare entity accounting for approximately 5% of all Hodgkin lymphoma (HL) cases. Pathological and clinical features differ from classical HL (cHL). Pathologically, the malignant lymphocyte predominant (LP) cells stain consistently positive for CD20 and are negative for CD30. Clinically, NLPHL often has a rather indolent course. Despite of these differences, the first-line treatment of NLPHL is mostly very similar to cHL. However, analyses on the long-term course of patients with NLPHL who were treated identically to cHL are scarce.
Aims: To shed more light on characteristics and outcome of NLPHL patients treated identically to cHL, we performed an analysis using the database of the German Hodgkin Study Group (GHSG).
Methods: A total of 471 patients with NLPHL who had received first-line treatment within the randomized GHSG HD7-HD15 trials for newly diagnosed HL were identified. The studies were conducted between 1993 and 2009. Patients at all stages (early favorable: HD7, HD10, HD13; early unfavorable: HD8, HD11, HD14; advanced: HD9, HD12, HD15) were included.
Results: Among the 471 NLPHL patients, the median age was 39 years; 76% of patients were male; 53% of patients had early favorable, 16% had early unfavorable and 31% had advanced-stage disease. Study treatment consisted of ABVD- or BEACOPP-based chemotherapy alone, radiotherapy (RT) alone or combined-modality treatment (CMT). After a median observation of 9.2 years, the 8-year progression-free survival (PFS) rate for the whole patient group was 81.3% (83.2% for early favorable, 85.2% for early unfavorable, 76.2 for advanced stages). 80 of 471 patients (17%) had refractory disease or relapsed during the course of follow-up (primary disease progression: 8 patients; early relapse: 6 patients; late relapse: 66 patients). Second malignancies including histological transformation into aggressive B-cell non-Hodgkin lymphoma (NHL) occurred in 48/471 patients (10%) (solid tumor: 25 patients; leukemia: 7 patients; NHL: 13 patients; unspecified malignancy: 4 patients). For all 471 patients included in the present analysis, the 8-year overall survival (OS) rate was 93.3% (95.1% for early favorable, 98.6% for early unfavorable, 87.4% for advanced stages). A total of 43 deaths were observed during follow-up resulting in a death rate of 9%. However, only a minority of these deaths was NLPHL-related (n=10). In contrast, most patients died from second malignancies (n=20) or due to other causes (n=13) such as heart failure and lung disease.
Summary/Conclusions: Taken together, the results from this large analysis on NLPHL patients prospectively treated and followed within randomized clinical studies for newly diagnosed HL indicate an excellent lymphoma-specific outcome. Nonetheless, further treatment optimization is necessary as the majority of the observed deaths were not NLPHL-related but due to second malignancies or other treatment-related late effects. Thus, future clinical trials including NLPHL patients should evaluate whether it is possible to reduce the treatment intensity without compromising efficacy. This goal may be achieved by the partial replacement of conventional chemotherapy by targeted drugs such as anti-CD20 antibodies as well as the reduction of RT fields and doses.

P276

ADVANCED HODGKIN LYMPHOMA IN THE EAST OF ENGLAND CANCER NETWORK: A 10-YEAR COMPARATIVE ANALYSIS OF OUTCOMES FOR ABVD AND ESCALATED-BEACOPP TREATED PATIENTS AGED 16–59

J. Russell[1,*], A. Collins[2], A. Fowler[3], M. Karanth[4], C. Saha[2], V. Shyamsundar[1], S. Docherty[1], K. Maw[5], J. Padayatty[6], A. Hodson[7], J. Wimperis[2], S. Sadullah[5], N. Grigoropoulos[1], B. Uttenthal[1], G. Follows[1]
[1]Cambridge University Hospitals NHS Foundation Trust, Cambridge, [2]Norfolk and Norwich University Hospital, Norwich, [3]Peterborough City Hospital, Peterborough, [4]West Suffolk Hospital, Bury Saint Edmunds, [5]James Paget University Hospital, Great Yarmouth, [6]Queen Elizabeth Hospital, King's Lynn, [7]Ipswich Hospital, Ipswich, United Kingdom

Background: The majority of young patients with advanced-stage Hodgkin lymphoma (HL) in the UK are managed with ABVD. However, following publication of the HD9 trial results in 2009, escalated-BEACOPP (escB) was introduced by some UK centres to improve disease control in poor-risk patients.
Aims: We present a 10-year retrospective multicentre analysis for advanced-stage HL patients, aged 16–59, diagnosed between 2004–2014 in the East of England Cancer Network and treated predominantly outside of clinical trials. Our study period includes the 5 years before, and after, the introduction of escB. We estimated the 5-year progression-free survival (PFS) and overall survival (OS) rates for the whole cohort, and treatment subgroups, to assess the impact of escB on survival outcomes.
Methods: We collected data retrospectively from 8 hospitals in the East of England using electronic medical records and cancer registry data. Only patients with a minimum follow-up of 18 months from diagnosis were included. The 5-year PFS and OS were estimated using the Kaplan-Meier method, and subgroups were compared using the standard log-rank test.
Results: We identified 250 patients (stage IIA bulk–IVB) treated in the East of England Cancer Network over a 10-year period from a referral population of 2.64 million (incidence: 0.95 cases per 100,000). Six of the 8 centres introduced escB for poor-risk patients, as determined by physician and patient choice; 44 patients were treated with escB, 202 with ABVD, 3 with alternative regimens, and 1 died pre-treatment. The median age at diagnosis was 35 years (16–59) and the median follow-up was 72 months (19–139). The 5-year PFS for all patients was 82% and 5-year OS was 92%. There was evidence of a physician–patient preference to treat poor-risk patients with escB, as a greater proportion of escB patients had a high international prognostic score (IPS 3+) than in ABVD patients (escB 75% *vs* ABVD 38%, p<0.0001). For the whole cohort, PFS was better for patients treated with escB compared with ABVD (5-year PFS 95% *vs* 80%; HR 4.3 (95% CI:1.97–9.7), p=0.0261), but there was no difference in OS (5-year OS 97% *vs* 92%; HR 2.6 (95% CI:0.69–10.4), p=0.312). However, patients with IPS 3+ had both a PFS and OS advantage when treated with escB compared with ABVD (5-year PFS 96% *vs* 74%; HR 9.24 (95% CI:3.43–24.89), p=0.012: 5-year OS 100% *vs* 84%; p=0.0325). Twenty-nine ABVD patients and 3 escB patients had at least 1 subsequent stem cell transplant (including 6 allografts post-ABVD and 3 allografts post-escB), and there was equal use of consolidation radiotherapy between regimens (11% of both ABVD and escB patients). Treatment-related infertility is an important consideration for escB patients. In our patient population, of the 20 pre-menopausal women treated with escB, 11 of the 14 (78.6%) aged <30 years at diagnosis regained menstrual periods during follow-up, 5 (45.5%) of whom subsequently conceived (including 6 live births, 1 miscarriage, and 1 termination). Only 1 of the 6 (16.7%) pre-menopausal women aged >30 years at diagnosis regained menstrual periods, which were not sustained beyond 3 years' follow-up.
Summary/Conclusions: Our data reflect clinical trials results which indicate a first-remission PFS but not OS advantage for unselected young advanced-stage HL patients treated with escB compared with ABVD. However, our data strongly suggest that patients with a poor IPS score derive a PFS and OS benefit from treatment with escB compared with ABVD.

P277

IMPACT ON SURVIVAL OF EARLY DETECTION OF RECURRENCE IN THE FOLLOW-UP OF HIGH RISK HODGKIN LYMPHOMA IN FIRST COMPLETE REMISSION

N. Pugliese[1,*], L. Simeone[1], R. Della Pepa[1], C. Giordano[1], I. Cappuccio[1], I. Zacheo[1], G. Campagna[1], C. Cerchione[1], P. Zeppa[2], C. Salvatore[3], F. Pane[1], M. Picardi[1]
[1]Hematology, University of Naples Federico II, Naples, [2]Department of Medicine and Surgery, University Medical School, Salerno, Salerno, [3]Department of Economics, University of Molise, Campobasso, Italy

Background: Despite the high complete response (CR) rate to anthracycline-including first-line therapy, approximately one-third of patients with advanced-stage Hodgkin lymphoma (HL) relapses. Many relapses (30–50%) are clinically asymptomatic, without any physical and/or laboratory signs. For patients at high-risk of relapse, a close monitoring, based on imaging procedures is justified if an early detection of recurrence would allow a timely administration of salvage therapy and a survival improvement.
Aims: The purpose of this study was to evaluate the response rate to salvage therapy of relapsed HL by comparing patients who received surveillance with conventional clinical assessments *versus* patients who received surveillance with imaging procedures. The primary end-point was to assess the rate of CR to salvage therapy at first relapse (confirmed by FDG PET/TC performed before ASCT). Secondary endpoints were: the overall rate of recurrence after first CR, the stage and extranodal involvement at relapse, and the disease-free survival (DFS), from the end of salvage treatment.
Methods: Between June 2001 and December 2009, we analyzed 306 patients with high-risk HL in CR after anthracycline-including induction treatment. In this case-control study, the first cases (n=156) consisted of patients who received a conventional follow-up program including symptom assessment, blood tests and physical examination; in these patients imaging procedures were performed only in case of suspected relapse (Historical group). Subsequent patients (n=150) received routine imaging procedures comprising ultrasonography (US) for the evaluation of superficial, anterosuperior mediastinal, abdominal, and pelvic lymph nodes (SMAP US), and chest radiography (CXR), as integrated part of the follow-up strategy (Imaging group). Follow-up procedures were performed at 4, 8, 12, 16, 20, 24, 30, 36, 48, 60, 84, and 108

months after treatment discontinuation in both groups. Relapses were documented by histologic examination in both groups. When relapse was documented all patients received salvage therapy with high dose chemotherapy (DHAP), for at least two courses, followed, in case of CR, by ASCT.
Results: After a median 62-months observation (range, 4–108), 83 patients, evenly distributed in the two groups, had a relapse of disease. Of these, 29 of 43 patients (67.4%) of the historical cohort *vs* 17 of 40 patients (42.5%) of the imaging cohort, showed a larger spread of disease at restaging, *i.e.* stage superior to IIB, and a more frequent extranodal involvement, 10/43 (23.3%) patients in the historical group *vs* 3/40 (7.5%) patients in the imaging group (p=0.01). Furthermore, if we considered only asymptomatic patients, one recurrence was detected in 26 of 43 patients in the imaging group and 17 of 40 patients in the historical group, p=0.02. CR rate with second line therapy were higher in the imaging group (27, 67.5%) compared with the historical group (19, 44.2%; p=0.032). The 3-years DFS was 75% in the imaging group and 36% in the historical group, p=0.02.
Summary/Conclusions: This is the first prospective case-control study using SMAP-US plus CXR to monitor patients with advanced stage HL. We show that SMAP-US plus CXR is a valuable tool to improve follow-up in patients with a high risk of recurrence. Our data indicate that the early detection of HL recurrence allows to begin rescue therapy in patients with a more limited disease and, consequently, increase its effectiveness in terms of probability to response and DFS.

P278

LATER LINE DRUG TREATMENT PATTERNS OF CLASSICAL HODGKIN'S LYMPHOMA PATIENTS IN CANADA, FRANCE, GERMANY AND THE UNITED KINGDOM

K. Byrne[1,*], A. Juarez Garcia[2], P. Hallworth[1], S. Blackburn[1], M. Lees[3]
[1]Adelphi Real World, Bollington, United Kingdom, [2]WW HEOR, Bristol-Myers Squibb, Mexico City, Mexico, [3]WW HEOR, Bristol-Myers Squibb, Paris, France

Background: Whilst cHL is seeing increasing 'cure' rates, a cohort of patients remain who, due to multiple relapses, require 3rd (3L) or 4th (4L) lines of drug treatment. Real world treatment patterns for RRHL patients are currently less understood.
Aims: To understand the drug treatment patterns of cHL patients in 3rd or later lines.
Methods: Real-world data were collected through a cross-sectional survey administered to physicians in Canada (Ca), France (Fr), Germany (Ge), and the UK between May and Sep 2016. Physicians provided data on the last 8 cHL patients receiving 3rd or 4th line drug treatment. Data captured included demographics, disease history and treatment patterns. Auto/allo stem cell transplants (auto/alloSCT) were not classified as a treatment line and limited data was available to determine when a SCT was received. Summary statistics were reported and differences between sub-groups assessed using chi-square tests.
Results: In total 116 physicians (Ca, 16; Fr, 31; Ge, 44; and UK, 25) provided information on 959 cHL patients (Ca, 128; Fr, 243; Ge, 351; and UK, 237) on 3rd or later lines of drug treatment. Data for 954 cHL patients on 3rd line drug treatment was captured. Patients had a mean age of 54.0 years (SD: 16.79) at the point of data capture. 57% were male, 43% female. 30% had bulky disease. 84% of patients had been tested for the Epstein Barr virus (EBV), 36% confirmed as positive. The most commonly prescribed 3rd line drug treatment was a brentuximab-vedotin (BV) based regimen (35%). BV use was significantly different across the markets; Canada (34%), France (35%), Germany (30%) and the UK (44%) (p=0.010). The next most commonly prescribed 3rd line treatments were DHAP (8%), BEAM (7%) and bendamustine (7%). 4% of 3rd line patients received a PD-1 inhibitor. Of 3rd line BV patients the majority received ABVD (69%) or BEACOPP (19%) at 1st line. Their most common 2nd line drug treatments were DHAP (21%), ICE (10%), ESHAP (9%) and BEACOPP (9%). 59% of all 3rd line BV patients had undergone an auto/alloSCT at some point during their treatment history. Of 3rd line patients receiving non BV-based regimens 6% had been treated with BV previously (1st / 2nd line). Of 3rd line patients treated with a PD-1 inhibitor 7% had been previously treated with BV. Data for 453 cHL patients on 4th line drug treatment was captured. 4th line patients had a mean age of 55.5 years (SD: 16.79) at the point of data capture. 56% were male, 44% female. 83% had been tested for EBV, 38% confirmed positive. 30% of 4th line patients received a BV based regimen – BV use across markets was significantly different; Canada (20%), France (38%), Germany (23%) and the UK (36%) (p=0.007). At 3rd line this cohort had most commonly received DHAP (16%), BEAM (15%) or ICE (11%). 5% of 4th line BV patients also received a BV based regimen at 3rd line. 129 4th line patients had received a BV regimen at 3rd line. At 4th line 38% of this cohort received a PD-1 inhibitor, 19% bendamustine and 9% gemcitabine.
Summary/Conclusions: Real-world data indicates an unmet medical need for cHL patients with multiple relapses, reinforced by the use of PD-1 inhibitors in those relapsing post BV based regimen at 3rd line. There also appears to be no clear standard of care at 3rd line, again highlighted by use of a range of regimens and PD-1's.
This study was sponsored by Bristol-Myers Squibb.

P279

CHEMOTHERAPY AND RADIATION IMPROVE SURVIVAL IN EARLY STAGE CLASSICAL HODGKIN LYMPHOMA, A STATEWIDE CANCER REGISTRY ANALYSIS.

H. Saeed[1,*], R. Shrestha[1], J. Nee[2], E. Durbin[2], M. Zia[1], R. Ramlal[1], G. Monohan[1], R. Herzig[1], R. Fleischman[1], G. Hildebrandt[1]
[1]Internal Medicine-Division of Hematology and BMT, [2]Kentucky Cancer Registry, University of Kentucky- Markey Cancer Center, Lexington, United States

Background: Early stage classical Hodgkin Lymphoma (cHL) has been shown to have an excellent outcome. Recent studies have therefore focused on decreasing the toxicity that results from the addition of radiation therapy to chemotherapy. However, it remains unclear whether omitting radiation as part of the initial therapy of cHL is associated with a similar survival
Aims: The primary aim of this study is thus to investigate the outcomes observed in a statewide cancer registry for cHL patients treated with chemotherapy alone *vs* patients treated with both chemotherapy and radiation.
Methods: All adult patients (older than 18) diagnosed with cHL in Kentucky Cancer Registry (KCR) from 2005-2014 were retrospectively reviewed. Baseline characteristics including age at diagnosis, gender, histology, stage, B symptoms, extranodal involvement, and the site involved were collected. First line treatment modalities as well as overall survival outcomes were reviewed. Stage I and II patients without B symptoms were considered favorable, while those with B symptoms were considered unfavorable. Patients with stage III and IV disease were given an advanced stage designation. To adjust for selection bias, patient deaths during the first 6 months of diagnosis were censored for overall survival analysis.
Results: A total of 961 patients were identified. Median age was 41 (range 18-91) and 60.9% (n=585) were younger than 50. The group included a mild predominance of males (55.5%). Only 1.7% (n=16) had extranodal involvement at presentation. Of those with known histology (78.6%), the most common was nodular sclerosis (71.2%), followed by mixed cellularity (22.8%), lymphocyte rich (3.8%) and lymphocyte depleted (1.9%). Median follow up time was 45 months (range 0-136). The 10-year overall survival for the favorable group (n=329) was 77% (95% CI: 71.1-88.8) *versus* 68% for the unfavorable group (n=144) and 42% for the advanced group (372) (p<0.001). There was no statistical difference in survival between stage I (n=170), and stage II (n=385) disease (p=0.99). Treatment modalities were then compared for the favorable risk group alone. Those who received chemotherapy alone (n=145) were compared to those who received combined chemotherapy and radiation (n=148) as their primary therapy. The 10-year overall survival for the cohort receiving chemotherapy and radiation was 87% compared to 75% for those receiving only chemotherapy (p<0.001) (Figure 1). When adjusted by multivariate analysis for risk factors affecting 10 year survival of the favorable cohort, only age <50 and the treatment modality were independently associated with a statistically significant difference in overall survival (HR of 0.11 (p<0.001) and 3.94 (p=0.001), respectively).

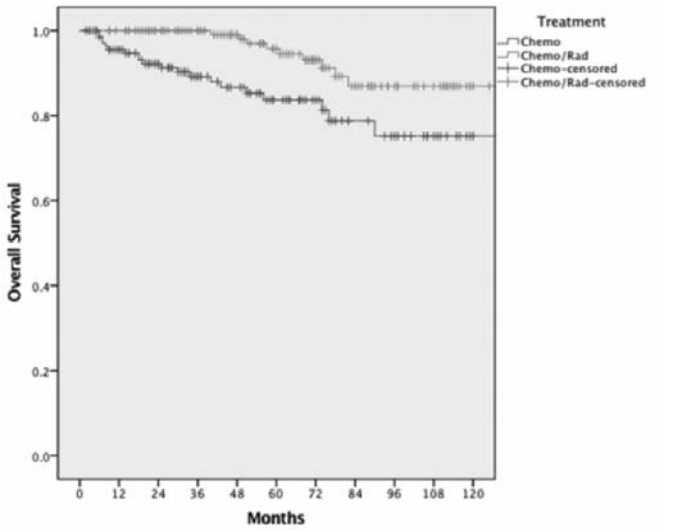

Figure 1.

Summary/Conclusions: Our large data cohort shows the presence of B symptoms was more prognostic than the number of nodal regions involved for early stage disease. Although the use of radiation as part of initial therapy for early stage disease might have increase long term toxicity, it continued to provide superior survival at 10 years.

P280

THE IMPACT OF TREATMENT WITH BRENTUXIMAB VEDOTIN ON OVERALL SURVIVAL OF PATIENTS WITH HODGKIN LYMPHOMA RELAPSED AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION. A NATIONWIDE POPULATION BASED ANALYSIS

Background: Patients with Hodgkin Lymphoma (HL) who relapse after autologous Stem Cell Transplantation (auto-SCT) have a dismal prognosis. Advanced disease stage, presence of B-symptoms, extranodal involvement at the time of relapse and duration of remission of less than 12 months are parameters associated with decreased overall survival (OS). Brentuximab Vedotin (BV), an anti-CD30 monoclonal antibody conjugated to a microtubule-disrupting agent, has shown clinical efficacy in HL. Although in the setting of post-auto-SCT relapse, BV produces an overall response rate of approximately 75% with a median progression free survival (PFS) of 9 months, the impact of BV on OS has not been addressed in previously published studies

Aims: To examine the impact of treatment with BV on OS of patients with HL relapsed after auto-SCT.

Methods: Data for patients with HL who underwent auto-SCT in Greece during the last 20 years were collected. Study group consisted of 214 patients who experienced post auto-SCT relapse. In order to examine the impact of BV on OS, patients were divided in 2 cohorts depending of the date of BV availability in Greece (January/2013). Cohort 1 consisted of 178 patients who relapsed before January/2013, while Cohort 2 consisted of 36 patients relapsed after BV became available. Patient's characteristics are shown in Table 1.

Table 1. Patients characteristics.

Parameter	Cohort 1 Before BV (no=178)	Cohort 2 After BV (no=36)	Significance
Age, median	29, (18-65)	32, (19-68)	n.s
Sex, M/F	106/72	22/14	n.s
B-symptoms, (yes v.s no)	60/118	10/26	n.s
Stage (I-II v.s III-IV)	71/107	14/22	n.s
Extranodal (yes v.s no)	76/102	15/21	n.s
Time from SCT to relapse (≤12 v.s >12 months)	137/41	27/9	n.s
Response to 1st salvage (yes v.s no)	105/73	18/18	n.s
Allo-SCT after relapse	28/178 (16%)	8/36 (22%)	n.s
BV after relapse	32/178 (18%)	36/36 (100%)	p<0.001
BV as 1st salvage after relapse	4/32 (12%)	20/36 (56%)	p<0.001

The following variables were included in a multivariate Cox proportional hazard regression analysis model: 1) age of patient, 2) Sex, 3) B-symptoms (yes *vs* no), 4) Stage of disease (I-II *vs* III-IV), 5) extranodal disease, 6) time from auto-SCT to relapse (≤12 *vs* >12 months), 7) Relapse before or after BV availability (Cohort 1 *vs* Cohort 2). In order to exclude any confounding effect of subsequent treatments, analysis was performed by censoring patients at the time of allogeneic SCT or treatment with immune checkpoint inhibitors (IC-inhibitors).

Results: In multivariate analysis the following variables were statistically associated with OS: 1) The presence of B-symptoms [HR=2.07, (95% CI, 1.39-3.07), p<0.001] and 2) Relapse in less than 12 months after auto-SCT [HR=2.02, (95% CI, 1.22- 3.35), p= 0.005] were associated with decreased OS, while 3) Response after 1st salvage [HR=0.46, (955 CI, 0.31- 0.68), p<0.001], and 4) BV availability [HR=0.36, (95% CI, 0.16-0.79), p= 0.011] were associated with increased OS (Figure 1). Similar results were obtained when analysis was performed without censoring patients at the time of allo-SCT or treatment with IC-inhibitors (data not shown).

Summary/Conclusions: Patients in Cohort 2 survived longer even when censored for allo-SCT or treatment with IC-inhibitors. All patients in Cohort 2 treated with BV while only 18% of patients in Cohort 1 received treatment with BV. The results of our study strongly suggest that BV improves OS in patients with HL relapsed after auto-SCT. To our knowledge this is the first study showing an OS advantage of treatment with BV.

Background: The programmed death-1 (PD-1) inhibitors have been approved by FDA for patients who relapse following autologous stem cell transplantation and brentuximab vedotin (BV) therapy.

Aims: This retrospective multicenter study aimed to provide information about the efficacy and safety of nivolumab in the "real-life" setting in Turkey.

Methods: 23 centers from Turkey participated in this study. Eligible patients were required those treated with at least 1 course of nivolumab and with available radiological response evaluation. The decision about inclusion of patients with organ dysfunction was made by the attending physician. Patients received nivolumab via a named-patient program, and there was no restriction for BV- and/or transplantation-naïve cases. Nivolumab was adminstered at a dose of 3 mg/kg iv infusion over 60 min q2wk in outpatient setting until death of any cause, unacceptable toxicity, withdrawal of consent, or primary physician's decision. The study was approved by the local ethical commitee. The primary endpoint was the overall response rate (ORR); secondary endpoints were overall survival (OS), PFS, and safety. The response was assessed by positron-emission tomography/computed tomography or CT. Early radiological evalua-

tion was defined as imaging at or before week 12 of treatment, whereas late radiological evaluation was performed at or after week 16. Response evaluation was performed according to the Lugano Classification and its update regarding immunomodulatory therapy.

Results: Between 06/2015-11/2016, 87 patients were enrolled in a name-based program in Turkey. Two, 19, and 3 patients who had not yet received nivolumab, had not reach the time for early radiological evaluation, and who died before any radiological evaluation were excluded from the analysis. Thus, 63 patients from 23 centers were retrospectively analyzed. Median follow-up was 6 months, median age was 29 (18-75) and patients had a median 5 (2-11) previous lines of therapy. 44 patients (70%) had been treated by stem cell transplantation (SCT) and 48 (76%) patients had been treated by BV. The ORR was 68% with 15 CR (95%CI 0.020-0.28; CR 26%, PR 42%, SD 12%, PD 20%) among 59 patients evaluated in 12 weeks of nivolumab treatment. The ORR was 67% with 9 (24%) patients with CR after 16 weeks of treatment (95%CI 0.004-0.26; CR 24%,PR 43%, SD 6%,PD 27%). Estimated OS was 95% (95%CI 0.80-0.98) and estimated PFS was 71% (95%CI 0.55-0.82) at 12-months. Median OS was not reached, while, according to the late response rates, the median PFS was 14 months. However, it was only 3 months in patients with PD at the late radiological evaluation. Regarding responses to last treatment prior to nivolumab, we detected that 28 (67%) of 42 PD cases had objective early responses and 70% of PD cases had ORR in the late response evaluation (CR in 4, PR in 12 pts). 8 patients underwent transplantation following nivolumab. Among 5 patients who had been treated by allo-SCT, 4 had CR at the time of transplantation and they are alive with ongoing response. Safety profile was acceptable and only two patients required cessation of nivolumab due to serious adverse events: one due to autoimmune encephalitis and one due to aggravation of graft *versus* host disease. At the time of analysis, 40 cases were still on nivolumab treatment (64%). Among the 40 cases with early objective responses to nivolumab, 35 (88%) showed ongoing objective responses. All 24 cases with objective responses in the late evaluation had ongoing responses at the time of analysis (Figure 1).

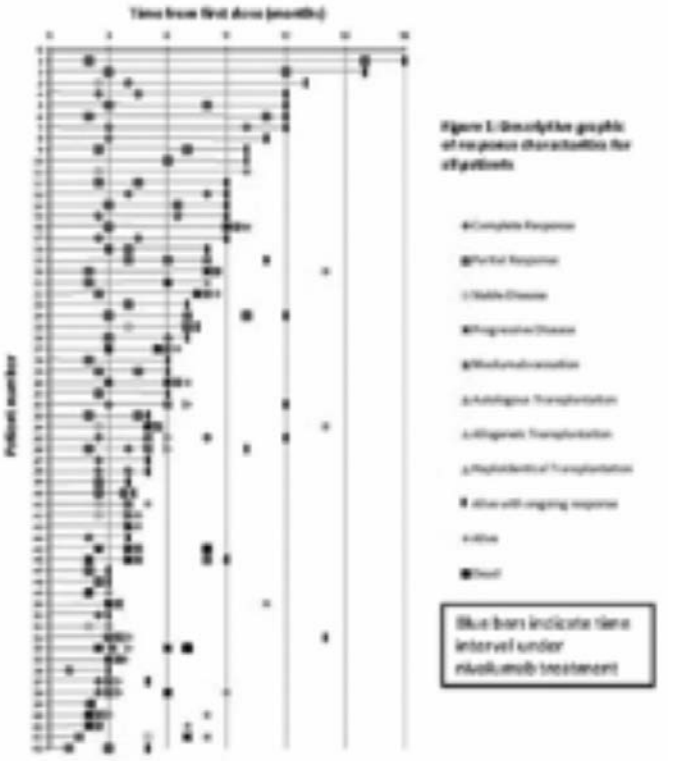

Figure 1.

Summary/Conclusions: In conclusion PD-1 blockers are new options to meet the unmet need in patients with cHL refractory to BV treatment, and possibly a bridge for these patients before transplantation.

Background: In classical Hodgkin lymphoma (cHL) the low representation (1-5%) of Reed-Sternberg cells (RS) challenged tumor genotyping on the diagnostic tissue biopsy. Consistently, the mutational profile of newly diagnosed cHL is poorly characterized, and the genetics of refractory disease is completely unknown. Cell free DNA (cfDNA) is shed into the blood by tumor cells undergoing apoptosis and can be used as source of tumor DNA for the identification of somatic mutations. In addition cfDNA is representative of the entire tumor heterogeneity, thus allowing the identification of mutations from tumor cells residing in non-biopsied sites.

Aims: This study aims: i) at providing the evidence that the mutational profile of cHL can be tracked by using plasma cfDNA; and ii) at characterizing the genetics of newly diagnosed cHL and, for comparative purposes, of refractory cHL.

Methods: The study incudes 28 newly diagnosed cHL and 9 chemorefractory cHL. All cases were provided with cfDNA from plasma collected at baseline, before treatment start, and paired DNA from granulocytes as source of germline DNA to filter out polymorphisms and sequencing noise. Paired genomic DNA from formalin fixed paraffin embedded (FFPE) tumor tissue biopsies was available for 17 patients, including 3 cases for which RS enriched areas were macrodissected. A targeted resequencing panel optimized to include the coding exons and splice sites of 77 genes (192Kb) that are recurrently mutated in B-cell lymphomas was used for genotyping. Libraries were prepared from plasma cfDNA, germline gDNA and tumor gDNA according to the CAPP-seq targeted enrichment strategy (Nimblegen) and subjected to ultra-deep-next generation sequencing (NGS) on the MiSeq platform (Illumina). The sequencing was tailored to obtain a depth of coverage >2000x in >80% of the target region in all samples, which allowed a sensitivity of $3x10^{-3}$. The somatic function of VarScan2 was used to call non-synonymous somatic mutations, and a stringent bioinformatic pipeline was applied to suppress tha background noise and to filter out sequencing errors.

Results: In newly diagnosed cHL patients, genotyping of plasma cfDNA identified non-synonymous somatic mutations in *STAT6* (43%), *TNFAIP3* (43%), *ITPKB* (32%) *B2M* (21%), *GNA13* (14%), *CIITA* (7%), *XPO1* (7%) and *CD58* (4%) among the most recurrently affected genes (Figure 1A-B). In refractory cHL patients, genotyping of plasma cfDNA identified non-synonymous somatic mutations in *ITPKB* (44%), *TNFAIP3* (33%), *KMT2D* (33%), *B2M* (33%), *GNA13* (33%), *XPO1* (22%), *TET2* (22%), *IKBKB* (22%), *BIRC3* (22%) and *STAT6* (22%) among the most recurrently affected genes. Mutations of *KMT2D* (33%) and *TET2* (22%) were enriched in refractory cHL patients compared to newly diagnosed cases, suggesting that they contributed to the chemorefractory phenotype (Figure 1C-D). By using highly sensitivity techniques, most of the mutations discovered in cfDNA were also identified in pair tumor DNA from the tissue biopsy and/or macrodissected RS cells, thus confirming their tumor origin (Figure 1F). By pathway analysis, the mutational profile pointed to the involvement of PI3K/AKT signaling, cytokines signaling, NF-kB signaling and the immune escape in cHL. *ITPKB* (a negative regulator of the PI3K/AKT signaling pathway) was specifically mutated in cHL across aggressive B cell lymphomas.

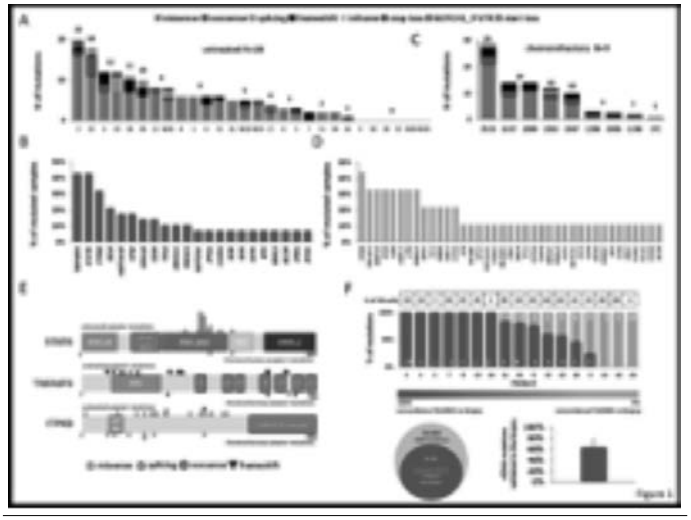

Figure 1.

Summary/Conclusions: This study provides the evidence that cHL can be genotyped using plasma cfDNA as source of tumor DNA, pointed to a non overlapping genotype between newly diagnosed and refractory cases, and identified *ITPKB* as a new gene specifically involved in ~30-50% of cHL patients.

P283

FDG PET-CT MAYBE A USEFUL TOOL TO IDENTIFY DOXORUBICIN INDUCED CARDIOTOXICITY IN HODGKIN LYMPHOMA

G. Sambuceti[1,*], E. Arboscello[1], P. Spallarossa[1], M. Miglino[1], M. Bauckneht[1], F. Fiz[1], S. Morbelli[1], G. Ferrarazzo[1], A. Bellodi[1], A. Da Col[1], D. Avenoso[1], F. Ballerini[1], M. Bergamaschi[1], L. Mitscheunig [1], M. Sarocchi[1], C. Brunelli[1], M. Gobbi[1], R. Lemoli[1]
[1]IRCCS San Martino - IST, Genova, Italy

Background: Doxorubicin (DXR) induced cardiotoxicity is related to several mechanisms, including interference of mitochondrial respiratory chain and acceleration of glycolysis.We previously reported that this treatment may enhance myocardial FDG uptake.
Aims: The present study aimed to verify whether this metabolic response on serial PET/CT imaging can predict myocardial function, non-invasively evaluated by follow-up echocardiography (ECHO).
Methods: 18F-FDG PET/CT of 25 patients affected by Hodgkin Disease (HD), treated following ABVD scheme were analyzed. Inclusion criteria were: 1) availability of 4 consecutive PET/CT scan for staging (PET1), interim (PET2), post-therapy (PET3) and six months follow-up evaluation (PET4); 2) full remission after two ABVD cycles; 3) normal baseline EKG and ECHO findings and 4) no concurrent treatment with external thoracic radiotherapy. A volume of interest was manually drawn on the left ventricular myocardium. Average standardized uptake value within this region was normalized for the corresponding blood pool index measured in the inferior vena cava to obtain LV-SUV. All patients underwent a 12 months cardiological follow-up assessment encompassing clinical evaluation, EKG and ECHO. A cardiologist unaware of PET findings performed this procedure
Results: LV-SUV progressively increased from PET1 to PET4 in 6 patients (24%, 2 females, mean age 39±17, termed "increasers") being 1.34±0.9, 3.34±2.6, 4.32±2.8 and 4.43±1.5 respectively. In the remaining 19 patients (76%, 7 females, 36±14), FDG uptake showed a largely variable response without any progressive increase. Accordingly, the ratio between PET4 and PET1 LV-SUV in the two subgroups was 3.85±0.8 and 1.06±0.4, respectively ($p<0.001$). Up to six months after therapy discontinuation, none of the 25 patients showed signs or symptoms potentially related to DXR cardiotoxicity. However, late follow-up ECHO detected the appearance of first-degree diastolic impairment with respect to baseline in 9 of the 25 examined patients (36%, 4 females, mean age 36 ±18). This finding occurred in 5/6 "increasers" (83%) and in only 4/19 non-increasers (21%) ($p<0.001$).
Summary/Conclusions: The present data indicate that DXR related myocardial damage can be preceded by an enhanced glucose uptake. 18F-FDG PET/CT imaging might represent a useful tool to identify high-risk patients and to implement personalized program to monitor and prevent DXR-induced cardiotoxicity.

Iron metabolism, deficiency and overload

ELEVATED SYSTEMIC HEME AND IRON LEVELS AS RISK FACTORS FOR VASCULAR DYSFUNCTION AND ATHEROSCLEROSIS: EVIDENCE FROM B-THALASSEMIA AND HEMOCHROMATOSIS COHORT STUDIES

F. Vinchi[1,*], G. Porto[2], A. Silva[2], R. Sparla[1], G.M. Vercellotti[3], J.D. Belcher[3], E. Fibach[4], H. Zreid[5], R. Rasras[6], M.W. Hentze[7], H. Ghoti[8], M.U. Muckenthaler[1], E.A. Rachmilewitz[9]
[1]Molecular Medicine Partnership Unit (MMPU), University of Heidelberg & EMBL, Heidelberg, Germany, [2]University of Porto, Porto, Portugal, [3]Vascular Biology Center, University of Minnesota, Minneapolis, United States, [4]Department of Hematology, The Hebrew University Hadassah Medical Center, Jerusalem, Israel, [5]Department of internal Medicine, AlShifa hospital, [6]Laboratory department, European Hospital of Gaza, Gaza, Palestinian Territory, Occupied, [7]European Molecular Biology Laboratory (EMBL), Heidelberg, Germany, [8]Department of Hematology, Assuta Medical Center, Tel Aviv, [9]The Edith Wolfson Medical Center, Holon, Israel

Background: Increasing evidence from animal studies suggests that free heme exerts vasculotoxic, pro-inflammatory and pro-atherogenic effects due to its ability to trigger endothelial and immune cells activation. Moreover, we recently demonstrated a role for iron in the pathogenesis of atherosclerosis, analyzing a mouse model of type IV hereditary hemochromatosis, hallmarked by severe iron overload. We also showed that iron-deficient diet and chelation therapy prevent atherosclerosis progression in those mice.
Aims: Here we aimed at evaluating the clinical relevance of these findings and whether parameters of vascular status correlate with iron levels and suggest a predisposition to vascular dysfunction and atherogenesis in iron-overloaded individuals.
Methods: To this purpose we examined serum samples from a cohort of patients with β-thalassemia major and intermedia, who received recurrent blood transfusions but inconsistent chelation therapy, and a cohort of patients with hereditary hemochromatosis (HFE ^{C282Y} homozygous mutation), treated with phlebotomy.
Results: β-thalassemia patients show high systemic heme and iron levels, which correlate with a severe drop in the plasma scavengers for hemoglobin and heme, Haptoglobin and Hemopexin, respectively. Hemochromatotic patients show high systemic iron levels and reduced hepcidin levels. Consistently, in the two cohorts, transferrin saturation, non-transferrin bound iron (NTBI) and serum ferritin are elevated. Interestingly, both thalassemic and hemochromatotic patients present with high systemic levels of soluble adhesion molecules (sVCAM-1, sICAM-1, sE-Selectin, sP-Selectin) and reduced nitrotyrosine levels, hallmarks of endothelial activation and vascular dysfunction. In addition, they show increased serum lipid peroxidation, elevated circulating oxidized LDLs and high pro-inflammatory cytokines, which are known to promote atherosclerosis. All parameters significantly correlate with increased systemic heme and iron indices, including NTBI, as well as decreased scavenger levels.
Summary/Conclusions: These results emphasize the involvement of serum hemoglobin, heme and iron in the pathogenesis of vascular dysfunction in β-thalassemia and hemochromatosis and suggest a pro-atherosclerotic role for these molecules. These findings are relevant, on one side, for cardiovascular diseases and vasculopathy, when iron parameters are altered, and on the other, for iron overload disorders, where premature atherosclerosis might develop. Finally, our data highlight the key protective role of heme/iron scavengers and support the potential therapeutic benefit of chelation therapy to counteract heme-/iron-driven vascular toxicity and atherosclerosis in hemolytic and iron-overload conditions.

P285

REAL-WORLD ADHERENCE TO IRON CHELATION THERAPY: COMPARING A FILM-COATED TABLET VERSUS DISPERSIBLE TABLET OF DEFERASIROX

W. Cheng[1], Y. Xiao[2], P. Bobbili[1], A. Coe[3], Y. Hao[3], C. Paley[3], Q. Said[3,*], V. Huang[3], M.S. Duh[1], M. Blinder[4]
[1]Analysis Group, Inc., Boston, United States, [2]Groupe d'analyse, Ltée, Montreal, Canada, [3]Novartis Pharmaceuticals, East Hanover, [4]Washington University School of Medicine, St. Louis, United States

Background: Iron chelation therapy (ICT) is effective in removing excess iron and preventing iron overload-related complications in patients (pts) with transfusion-related iron overload. However, adherence to ICT has historically been suboptimal. While deferasirox (DFX) dispersible tablet (DT) has shown better adherence than other oral and non-oral ICT agents, adherence could be further improved. The recently approved DFX film-coated tablet (FCT) provides a simpler method of oral ICT administration, and was found to have improved patient adherence as compared to DFX DT in the recent ECLIPSE clinical trial (NCT02125877). Real-world evidence outside of a trial is lacking.
Aims: To assess and compare real-world adherence and persistence to ICT in pts switching from DFX DT to DFX FCT.

Methods: A retrospective pre-post cohort study was conducted in pts switching from DFX DT to FCT using pharmacy and medical claims (06/2014 - 05/2016) from the Symphony Health Solutions' Integrated Dataverse (IDV®) database. Eligible pts were ≥2 years old, had a diagnosis of an inherited or acquired hematological disorder requiring transfusions (*e.g.*, sickle cell disease, myelodysplastic syndrome), ≥2 DFX FCT claims (1st claim=index date), ≥2 DFX DT claims pre-index, and ≥6 months of continuous clinical activity (baseline period) pre-index. Medication possession ratio (MPR) (percentage of time with access to medication) was computed for DFX DT during the "DFX DT period" (from earliest DFX DT claim to index date) and for DFX FCT during the "DFX FCT period" (from index date to end of data availability/ICT switch). Proportion of days covered (PDC) and persistence (without a gap ≥30 or 60 days between claims) were assessed in the DFX DT and DFX FCT periods over fixed intervals of 3 and 6 months, which started from the index date in the DFX FCT period, or dispensing date of the most recent DFX DT claim prior to the beginning of a 3- or 6- month interval in the DFX DT period. Comparisons between the two periods were made using the Wilcoxon sign-rank test for continuous data and McNemar's test for dichotomized data.
Results: Of the 606 eligible pts, 56% were female, 64% were <35 years old, and 42% had transfusions during the baseline period. The median durations of the DFX DT and DFX FCT periods were 356.5 days and 290.0 days, respectively. Compared with adherence to DFX DT, adherence to DFX FCT was significantly improved across all measures. Mean MPR of DFX FCT *vs* DFX DT was 0.80 *vs* 0.76 (p<0.001); 60.9% pts had a mean MPR ≥0.8 during the DFX FCT period compared to 54.3% during the DFX DT period (p<0.01). Mean 3-month PDC of DFX FCT *vs* DT was 0.83 *vs* 0.71 (p<0.001); 50.0% pts had mean 3-month PDC ≥0.8 during the DFX FCT period compared to 34.5% during the DFX DT period (p<0.001). The proportion of pts with 3-month persistence to DFX FCT *vs* DFX DT (without a gap ≥30 days) was 87.2% *vs* 63.4% (p<0.01). Similarly consistent and significant results for PDC and persistence were observed using a 6-month time interval and/or a 60-day gap between claims.
Summary/Conclusions: Adherence and persistence to ICT was significantly improved in pts who switched from DFX DT to DFX FCT. Reasons for switching, which may contribute to improved adherence, were not examined in this study. Nevertheless, since the majority of pts were already adherent to DFX DT, the improvement with DFX-FCT suggests that ICT can be further augmented with this formulation. This real-world study complements the ECLIPSE trial results and supports previous evidence of improved adherence to DFX FCT.

P286

MEDIATION BY PATIENT-REPORTED OUTCOMES ON THE ASSOCIATION BETWEEN FILM-COATED VERSUS DISPERSIBLE FORMULATIONS OF DEFERASIROX AND SERUM FERRITIN REDUCTION: A POST HOC ANALYSIS OF THE ECLIPSE TRIAL

A.T. Taher[1,*], R. Origa[2], S. Perrotta[3], A. Kouraklis[4], K. Belhoul[5], V. Huang[6], J. Han[6], A. Bruederle[7], P. Bobbili[8], M.S. Duh[8], J.B. Porter[9]
[1]American University of Beirut Medical Center, Beirut, Lebanon, [2]Ospedale Pediatrico Microcitemico 'A.Cao', University of Cagliari, Cagliari, [3]Second University of Naples, Naples, Italy, [4]Hematology Division, Department of Internal Medicine, University of Patras Medical School, Patras, Greece, [5]Dubai Health Authority Thalassemia Center, Dubai, United Arab Emirates, [6]Novartis Pharmaceuticals Corporation, East Hanover, United States, [7]Novartis Pharma AG, Basel, Switzerland, [8]Analysis Group, Boston, United States, [9]University College London, London, United Kingdom

Background: The ECLIPSE clinical trial (NCT02125877) demonstrated that a new film-coated tablet (FCT) formulation of deferasirox (DFX) had a similar safety profile, with fewer patients (pts) experiencing severe gastrointestinal (GI)-related adverse events (AEs), and more favorable patient-reported outcomes (PROs) compared to the dispersible tablet (DT). PROs of FCT pts showed better adherence, satisfaction, palatability and fewer concerns about iron chelation therapy (ICT). FCT pts had a higher median absolute reduction in serum ferritin (SF) from baseline to the end of treatment (tx) (-350.0 *vs* -85.5 ng/mL), despite tx groups receiving similar mean actual ICT doses, suggesting better efficacy of FCT (Taher AT, *et al.* Am J Hematol. 2017). Since DFX FCT has the same active ingredient as DT and was developed to enhance pt adherence, it is hypothesized that the observed difference in efficacy may be due to differences in adherence. PROs may be a useful surrogate marker of actual pt adherence to ICT.
Aims: To estimate the proportion of the association between tx with DFX FCT *versus* DT and SF reduction from baseline that is mediated through PROs, in a *post hoc* analysis.
Methods: The ECLIPSE trial was a phase II, randomized open-label study in which 173 pts with transfusion-dependent thalassemia or myelodysplastic syndrome were randomized to receive DFX FCT (N=87) or DT (N=86) at average planned doses of 21.5 mg/kg/day (DT equivalent dose=30.7 mg/kg/day due to differing bioavailability) and 28.7 mg/kg/day, respectively. PROs were assessed at weeks 2, 3, 13, and 24 (end of tx) using the Palatability and modified Satisfaction with Iron Chelation Therapy (mSICT) questionnaires, the latter assessing 3 domain scores: adherence, satisfaction, and concerns. Frequency of GI-related AEs was assessed during the tx period. Mediation analysis, *i.e.*, comparing a model adjusted for hypothesized mediators to an unadjusted model (Lin DY, *et al.* Stat Med. 1997), was used to compute proportion mediated (PM). PM quantifies how much of the association between tx with DFX FCT *versus* DT and SF reduction from baseline is operationalized through pt-reported adherence score, other PRO scores, and frequency of GI-related AEs during tx. The analysis was adjusted for confounders including age, sex, race, underlying hematological disease, prior use of DFX DT, baseline level of iron overload severity, average planned dose, and number of blood transfusions on tx. Sensitivity analyses were conducted in subgroups of pts who had prior use of DFX DT (DT non-naïve), had thalassemia, and were DT non-naïve pts with thalassemia.
Results: The association between tx with DFX FCT *versus* DT and SF reduction was substantially mediated by pt-reported adherence (PM=66.6%, p=0.01). Pt-reported adherence, along with pt-reported satisfaction, concerns, and palatability scores, and frequency of GI-related AEs together mediated 76.7% of the association (p=0.02). The proportion mediated was increased in the DT non-naïve subgroup (PM=92.7%, p=0.03). Similarly, an increased PM was seen in the subgroup of DT non-naïve pts with thalassemia compared to all thalassemia pts (PM=70.1%, p=0.08 *vs* PM=56.5%, p=0.12, respectively).
Summary/Conclusions: Better PROs, especially increased pt-reported adherence, due to improved attributes associated with DFX FCT are significant intermediates of the association between tx with DFX FCT *versus* DT and SF reduction from baseline. The proportion mediated was increased in pts with prior DT exposure, suggesting their enhanced appreciation for DFX FCT over DT.

P287

ASSESSMENT OF THE PERFORMANCE OF A WIDELY AVAILABLE T2*/R2* LIVER IRON CONCENTRATION METHOD USED IN CLINICAL PRACTICE IN A POPULATION OF THALASSEMIA PATIENTS

N. Ngoc Trang[1], N.T. Thu Ha[2], D. Thai Ton[1], N. Khoi Viet[2], P. Minh Thong[1], N. Anh Tri[2], B. Quoc Khanh[2], M. House[3,4], W. Pang[4], S. Boulos[4], T. St Pierre[3,*]
[1]Radiology Department, Bach Mai Hospital, [2]National Institute of Hematology and Blood Transfusion, Hanoi, Viet Nam, [3]School of Physics, The University of Western Australia, Crawley, [4]Resonance Health, Claremont, Australia

Background: Measurements of liver iron concentration (LIC) by magnetic resonance imaging (MRI) have become established and validated in several research intensive centers. While the validity of spin density projection assisted (SDPA) R2-MRI together with a core laboratory service has been validated in routine clinical practice settings, methods relying on in-house establishment of data acquisition protocols and data analysis have not yet been validated in this way.
Aims: To determine the limits of agreement between measurements of LIC by a widely available T2*/R2* MRI method and a reference standard SDPA R2-MRI method in a routine clinical practice setting.
Methods: Thalassemia patients (N=100) referred by the National Institute of Haematology and Blood Transfusion, Hanoi, Vietnam for routine LIC measurement by MRI were prospectively recruited with informed consent. Patients were randomised to be scanned in either a Philips Ingenia or a Siemens Avanto 1.5T scanner. The LIC of each patient was measured twice, once by a T2*/R2* technique using freely available software and protocols (Iron Health Calculator: http://www.ironcalculator.com) and once by SDPA R2-MRI using a quality controlled core laboratory data analysis service (FerriScan®). Analysts using the T2*/R2* data analysis method were blinded from the SDPA R2-MRI results and vice versa. Reported data were analysed using the statistical methods of Bland and Altman.
Results: A plot of the T2*/R2* LIC against the SDPA R2-MRI LIC (Figure 1) shows the vast majority of the data falling below the line of equivalence indicating that the T2*/R2* method is underestimating the LIC relative to the SDPA R2-MRI validated reference standard. The geometric mean ratio of T2*/R2* LIC to SDPA R2-MRI LIC was 0.44 (95% CI 0.36 –0.55) indicating severe underestimation of LIC by the T2*/R2* method. The geometric mean ratios of the two LIC measurements were significantly different for the two scanners (0.28 for Philips and 0.68 for Siemens, p <0.0001) indicating that the bias of the T2*/R2* method against the reference standard is not universal but is dependent on both/either scanner type and/or data acquisition method. Bland Altman analysis indicates that 95% of pairs of measurements are predicted to have ratios between 3.73 and 0.05 indicating a very large random variability between the T2*/R2* method and the reference standard. The performance of the T2*/R2* method in predicting SDPA R2-MRI LIC values above the clinically relevant thresholds of 7 and 15 mg Fe/g dw is characterized in the Table 1 showing positive predictive values (PPVs) and negative predictive values (NPVs) together with their 95% CIs.

Table 1.

LIC Threshold	Positive Predictive Value	Negative Predictive Value
>7 mg Fe/g dw	1.00 (0.95 – 1.00)	0.23 (0.09 – 0.44)
>15 mg Fe/g dw	0.98 (0.89 – 1.00)	0.40 (0.26 – 0.54)

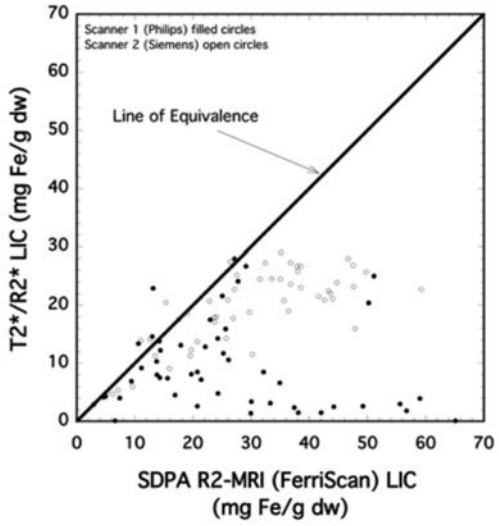

Figure 1.

Summary/Conclusions: The data indicate that the T2*/R2* method of measurement of LIC is not safe for routine clinical measurement of LIC because of the extremely poor NPVs which could result in inappropriate clinical decision making. The severe discrepancies of the T2*/R2* method from the reference standard are likely caused by several factors including non-optimal curve fitting algorithms, lack of a method to identify non-analysable data, and the use of a calibration curve from the literature generated from data acquisition and analysis methods different from those used locally. These or similar pitfalls are likely to be encountered in many MR centres using non-regulated MR methods of LIC measurement.

P288

SIMILAR TRENDS IN RENAL FUNCTION AS MEASURED BY SERUM CREATININE DURING LONG-TERM IRON CHELATION TREATMENT WITH OR WITHOUT DEFERASIROX IN PATIENTS WITH TRANSFUSIONAL HEMOSIDEROSIS

R. Origa[1,*], A. Piga[2], I. Tartagliona[3], G. Della Corte[4], A. Bruederle[5], J. Han[6], C. Castiglioni[7], G.L. Forni for Renal Chart Review Study Investigators[8]
[1]Ospedale Pediatrico Microcitemico 'A Cao', University of Cagliari, Cagliari, [2]University of Turin, Orbassano, Turin, [3]Università della Campania "Luigi Vanvitelli", Naples, [4]Università di Milano, Ca Granda Foundation IRCCS, Milan, Italy, [5]Novartis Pharma AG, Basel, Switzerland, [6]Novartis Pharmaceuticals Corporation, East Hanover, United States, [7]Novartis Farma SpA, Origgio, [8]Ospedale Galliera, Genoa, Italy

Background: Regular transfusion and iron chelation therapy (ICT) are often indicated for patients with β thalassemia, sickle cell disease (SCD) and other anemias, and can be lifelong requirements. As most patients now survive into adulthood and many experience prolonged exposure to ICT, there is increased risk of age-, disease- or drug-related complications, including changes in renal function. Evidence suggests that some patients receiving ICT experience changes in markers of renal function, mostly within normal limits, non-progressive and reversible with dose reduction and/or interruption. Recently, we reported a retrospective analysis of patients with transfusion-dependent anemias during a decade of deferasirox treatment indicating stable and a lack of any progressive worsening of renal function (Origa R *et al. Blood* 2016).
Aims: To assess serum creatinine (SCr) during long-term deferasirox treatment in subgroups of Italian patients with transfusional hemosiderosis who participated in the deferasirox registration studies and were then followed retrospectively.
Methods: Italian patients with β thalassemia, SCD, myelodysplastic syndromes or other anemias who received ≥1 deferasirox dose in the registration studies (studies 105, 106, 107, 108 or 109), had ≥1 post-baseline (BL) SCr measurement, and had medical records available were included. SCr values were collected retrospectively in 3-month periods from registration trial end until the latest patient assessment. Primary endpoint was SCr over time. SCr values during the retrospective period were evaluated by subgroups: here we report those who received only deferasirox and those who received no deferasirox but other ICT during the retrospective period.
Results: 282 patients were included in the retrospective study who received ≥1 deferasirox dose in registration studies; of these, during the retrospective period, 98 (35%) received only deferasirox (group A) and 62 (22%) received no deferasirox but other ICT (group B). In group A, mean (SD) age at first quarter was 25.9 (12.1) years and 36 (37%) were male; in group B, mean (SD) age at first quarter was 27.0 (10.9) years and 25 (40%) were male. The proportion of pediatric patients was 28% (n=27) in group A and 19% (n=12) in group B. Mean (SD) duration of deferasirox exposure in group A was 7.5 (1.7) years; mean daily deferasirox dose was 1440.0 (423.6) mg.
In both subgroups analyzed, mean SCr was within normal limits and remained stable over time during the retrospective period (Figure 1). Analysis in adults showed mean SCr values were stable over time. As expected in growing children who are gaining height and weight, pediatric mean SCr absolute values increased from baseline in proportion with an almost linear increase in muscle mass over time.

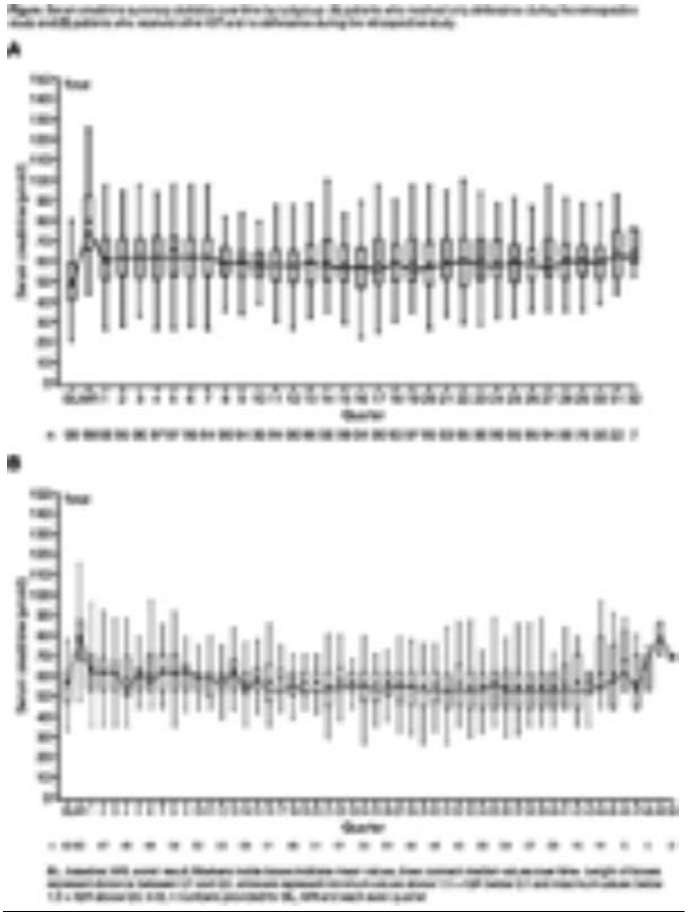

Figure 1.

Summary/Conclusions: This retrospective study of long-term renal safety in patients receiving iron chelation for transfusional iron overload suggests that long-term deferasirox treatment, or administration of ≥1 deferasirox dose followed by other chelators, did not have an overall detrimental long-term effect on renal function as monitored by SCr. This analysis provides no evidence of progressive renal function worsening over time, which is consistent with previous results demonstrating deferasirox has a mild, generally reversible renal hemodynamic effect.

P289

WHEN IRON LEADS TO RED CELLS (AND *VICE VERSA*): A COMPREHENSIVE PHENOTYPE -TOWARDS NGS/WES PATHWAY FOR THE DIAGNOSIS OF RED CELL AND IRON DISORDERS

M. Giansily Blaizot[1], S. Cunat[1], O. Guillot[1], G. Moulis[1], P. Aguilar Martinez[1,*]
[1]Hematology, Hopital Saint Eloi, Montpellier Cedex 5, France

Background: Despite thorough clinical and biological phenotypic investigations, a number of red cell disorders remain uncharacterized. In addition, some of them are accompanied by overt iron overload and can be initially misdiagnosed as disorders of genes involved in iron metabolism. Next Generation Sequencing (NGS) has become an attractive technique to decipher constitutional disorders as it allows analyzing a large number of disease-causing genes. However an initial complete clinical, biological and morphological assessment is mandatory to correctly orientate towards the correct gene panel and to interpret the various molecular variations identified. We have set up in our center, a specialized outpatient consultation for both iron and red cell disorders. Specialized phenotypic investigations including biological and morphological tests followed by standard or second level genotyping can be prescribed.
Aims: The aims of this study was to characterize the molecular background of patients with iron or red cell disorders, or with a possible combination of both, and to propose key steps towards this genetic diagnosis.

Methods: A cohort of 25 well characterized patients was analyzed. Eighteen were initially referred to our center for unexplained hyperferritinemia (HF), two for proven iron overload (IO) by MRI, 2 for chronic hemolysis and 3 for aregenerative anemia. A set of phenotypic tests was systematically assessed, including CBC, reticulocyte count, serum haptoglobin and measure of the Liver Iron Content (LIC) by MRI. For all patients with HF, causes linked to hepatic disease, inflammation and cancers were ruled out and standard HFE genotyping was performed. Phenotypic investigations failed to clearly identify the cause of the disorder. Therefore, each patient was tested for a panel of 32 genes involved either in iron homeostasis or hereditary anemias, using NGS. Libraries were obtained using the Custom SureSelectQXT Target Enrichment system (Agilent, Santa Clara Ca USA) and sequenced on a MiSeq platform (Illumina, San Diego, Ca, USA). Each deleterious variation was independently checked using conventional Sanger sequencing. Written informed consent was obtained from all the patients for NGS genetic analyses.
Results: Initial phenotypic reassessment allowed classifying the patients into 5 different groups: 1/ isolated hyperferritinemia (n=1) 2/ HF and IO (MRI ≥90 µmole/g dry weight) (n=17); 3/ hemolytic anemia (HA) without IO (n=2) ; 4/ HA and IO (n=2); 5/ aregenerative anemia with IO (n=3). Among patients with an initial diagnosis of iron disorder, the reticulocyte count identified 2 undiagnosed chronic fully compensated hemolysis. Systematic screening using the gene panel identified a total of 14 sequence variations of clinical significance in 9 different genes and 9 patients. An isolated mutation was found in 7 and 2 patients with an initial diagnosis of iron or of red cell disorder respectively. A combined anomaly of red cell and iron genes was identified in 3 patients who displayed IO and compensated hemolysis or anemia. Digenism involving an HFE C282Y/wt or C282Y/H63D genotype and another "iron gene" was also shown in 3 patients with IO (without anemia or hemolysis). No sequence variation of clinical significance was found in the sequenced genes of eleven of the studied patients.
Summary/Conclusions: On the phenotypic point of view, the present study highlights the importance to check for hematological data (CBC and reticulocytes) in patients with HF, because this can allow discovering fully compensated hemolysis and bringing towards a red cell disorder. On the other hand, it also underlines the importance to systematically check for IO all patients with a red cell disorder, who may display high LIC. Our present genotypic data (and previous ones) suggest a relative frequency of combined inherited disorders of iron and red cells, making the combined search for both disorders quite relevant in clinical practice. This is now possible with the use of NGS analysis, which allows sequencing large numbers of genes. For those patients with no identified mutation, approaches using whole exome or genome can be proposed as the next step.

P290

CHANGES IN LIVER IRON CONCENTRATION R2 MRI MEASUREMENT ACROSS DIFFERENT CHELATION REGIMENS IN PATIENTS WITH HEMATOLOGICAL DISORDERS: REAL-LIFE EXPERIENCE FROM LICNET

A. Vitrano[1], R. Rosso[2], A. Quota[3], D. Fiorino[4], E. Oliva[5], C. Gerardi[6], G. Roccamo[7], V. Spadola[8], A. Filosa[9], L. Tesé[10], G. Calvaruso[1], L. Pitrolo[1], L. Mistretta[1], F. Cassarà[1], A. Maggio[1,*]

Malattie Rare del Globulo Rosso, A.O.R.N. "A. Cardarelli", Napoli, [10]UOC Radiologia , AOOR Villa Sofia-Cervello, Palermo, Italy

Background: The liver plays a central role in iron regulation and remains the primary site of iron storage, with liver iron concentration (LIC) being a strong surrogate of total body iron. Both R2 and T2* can accurately measure LIC. R2 MRI is a robust and validated technique (FerriScan® Resonance Health Limited, Claremont, WA, Australia) approved by the FDA. The LICNET (Liver Iron Cutino NETwork) was established by Foundation Franco e Piera Cutino of Palermo and is addressed to diagnostics of liver iron overload by R2 MRI in subjects with hemochromatosis in haematological disorders. The LICNET protocol was approved on December 4, 2012 by our Ethics Committee. Baseline data from LICNET were, recently, published (Vitrano *et al.*, 2016, EJH).
Aims: The aim of this study was to evaluate longitudinal changes in LIC measurements across different iron chelation regimens in a real-life cohort of patients with transfusional iron overload included in LICNET.
Methods: This was retrospective cohort study of patients with haematological disorders attending 9 Italian centres participating in the LICNET who had two R2 MRI scans recorded in the database and receiving the same iron chelation in between. Bivariate comparisons were made using the chi-squared and Fisher's exact tests for categorical variables and the Wilcoxon or Mann–Whitney test for continuous variables.
Results: A total of 130 patients were evaluated in this analysis, with a median (range) age years of 35 (range: 6–78) and including 60 (46.2%) men. The underlying diagnoses were regularly transfused thalassemia major (n=86, 66.2%), thalassemia Intermedia (n=33, 25.4%), sickle cell disease (n=6, 4.6%), myelodysplastic syndrome (n=3, 2.3%), and Diamond-Blackfan anemia (n=2, 1,5%). The median duration (range) between the first and second MRI was 483 days (184-1076) and was comparable between iron chelation regimens. Median pre-transfusion hemoglobin level and blood requirement were similar at both MRIs.The median change in LIC (range) in mg Fe/g dw was not significant in patients receiving DFP (n=29, median change -1.9, p=0.55), DFX (n=52, median change -0.5, p= 0.515), DFO+DFP (n=10, median change -2.2, p=0.074), or other combinations (n=7, median change -1.3, p=1.000), while it decreased significantly on DFO monotherapy (n=32, median change -1.4,p=0.002). Among oral chelators, DFX showed to be more effective, during the period of the study, in stabilizing iron body burden in 65.4% patients, even if they had baseline LIC values <7mg Fe/g dw (median 4.0 mg Fe/g dw) and with similar response as combined treatment DFO+DFP (Figure 1).

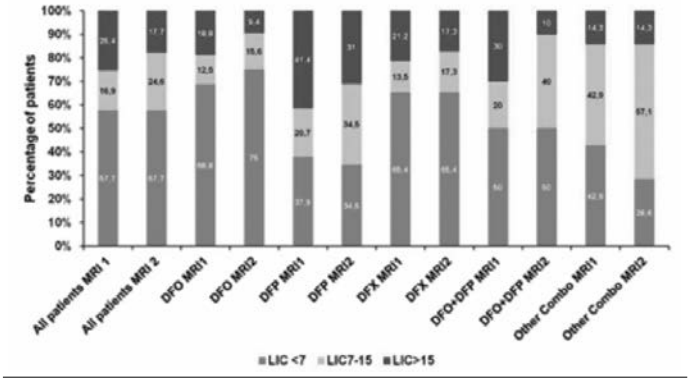

Figure 1.

Summary/Conclusions: This cohort study suggests that stabilization of LIC is achievable, during a median of 483 days, with different iron chelation regimens in real life experience, with considerable proportions of patients shifting to more favourable LIC categories. Therefore, the periodic determination of LIC by MRI has to be strongly recommended for management and prevention of iron overload and subsequent complications in haematological disorders.

P291

IN UTERO IRON STATUS AND AUDITORY NEURAL MATURATION IN FULL TERM INFANTS BORN TO MOTHERS WITH IRON DEFICIENCY ANEMIA

M. Elalfy[1], R. El-Farrash[1,*], H. Taha[2], E. Ismail[3], N. Mokhtar[4]
[1]Pediatrics Department, [2]Audiology Department, [3]Clinical Pathology Department, Faculty of Medicine-Ain Shams University, [4]Ministry of Health, Cairo, Egypt

Background: Iron deficiency is the most important cause of nutritional anemia and is the most common micronutrient deficiency worldwide, especially in developing countries. Iron is crucial for fetal brain development; hence, there is a paramount need for diagnostic neurofunctional screening that could identify low CNS iron stores. However, there are insufficient data regarding the effects of maternal iron deficiency anemia (IDA) on auditory neural maturation.
Aims: We aimed to evaluate the effect of maternal IDA on auditory neural myelination in full term neonates using the auditory brainstem evoked response (ABR) as noninvasive neurophysiological assessment tool.
Methods: This prospective case-control study was conducted at Ain Shams University Hospitals and included 100 neonates. Out of 223 pregnant women, 50 were diagnosed as having IDA anemia and 50 healthy mothers were enrolled as a control group. Neonates were studied focusing on anthropometric measures, hematologic profiles and iron status. Auditory brainstem response (ABR) test was done for the studied neonates within 48 hours after birth and at 3 months.
Results: Hemoglobin and iron profile were lower in neonates born to anemic mothers compared with controls. Of 100 neonates screened for ABR, 25 failed the test (all of them were born to anemic mothers). Neonatal birth weight, crown-heel length, BMI, occipitofrontal circumference (OFC) and mid arm circumference were significantly lower in neonates who failed the ABR test than those who passed it ($p<0.05$). Moreover, maternal and neonatal hemoglobin, red blood cells indices, serum iron, ferritin and transferrin saturation were significantly lower in neonates who failed the ABR test than those who passed it ($p<0.05$). Most neonates (88%) who failed the screening ABR test had latent iron deficiency (cord blood ferritin 11-75 µg/L). After 3 months, 85 underwent diagnostic ABR test which revealed significantly prolonged interpeak latencies I-III, III-V, and I-V among neonates of anemic mothers compared with the non-anemic group. All interpeak latencies were more prolonged in neonates with latent iron deficiency and those born to mothers with serum ferritin <15 µg/L. Logistic regression analysis showed that maternal hemoglobin and mean corpuscular volume were the significant independent variables that could predict neonatal ABR results.

Summary/Conclusions: IDA during late pregnancy adversely affects cord blood iron and hearing status. ABR results are closely related to the severity of maternal and neonatal iron status. Antenatal screening of pregnant mothers is needed to improve fetal iron status and prevent abnormal auditory maturation.

P292

THE RELATIONSHIP BETWEEN SERUM FERRITIN AND LIVER IRON CONCENTRATION IN PEDIATRIC CANCER SURVIVORS

M. House[1,2], K. Sadak[3], J. Lee[3], A. Smith[3], T. St. Pierre[1,2,*]
[1]Resonance Health, Claremont, [2]School of Physics, The University of Western Australia, Crawley, Australia, [3]Dept. of Pediatrics, University of Minnesota, Minneapolis, United States

Background: There is increasing recognition that pediatric cancer survivors are at risk of transfusion-related iron overload related to intensive treatment regimes and improved survival rates. Current screening approaches rely on serum ferritin (SF). However, little is known about the SF to liver iron concentration (LIC) relationship in pediatric cancer survivors and whether SF thresholds derived from other iron overload disorders or age groups are appropriate.
Aims: The aim of this study was to investigate the relationship between SF and LIC in pediatric cancer survivors and to determine SF thresholds for predicting clinically significant LICs in this patient group.
Methods: In this retrospective study, patient data were extracted on survivors with elevated ferritin or iron overload from the University of Minnesota Childhood Cancer Survivor Program research database. All patients were enrolled into the database via an informed consent process according to the guidelines of the University of Minnesota Institutional Review Board. Survivors were re-consented once they reached 18 years of age. Seventeen individual survivors were identified where both SF and LIC data were available and the time between the SF and LIC measurement was less than 30 days. Eleven of the 17 survivors had multiple SF measurements producing a final dataset with 34 pairs of SF and LIC measurements. Blood for serum ferritin was collected during clinic visits and analyzed by the University of Minnesota Medical Center, Fairview CLIA-certified clinical laboratory. Liver iron concentration measurements were made using spin density projection-assisted R2-MRI (FerriScan®). Linear regression was used to determine the relationship between SF and LIC. Receiver operating characteristic (ROC) curve analysis was used to assess the sensitivity and specificity of SF concentrations for predicting LIC.
Results: The average age of the cohort (6 females and 11 males) at their first SF/LIC measurement was 18.3 years (range 9 to 30.3 years). Acute lymphoblastic leukemia (N=5) and acute myeloid leukemia (N=4) were the most common diseases and 15 of the 17 survivors had received a haematopoietic stem cell transplant (HSCT). The average length of time between the final treatment and the first SF/LIC measurement was 5.4 years (range 0 to 12.5 years). A linear fit to all 34 LIC-SF measurement pairs (Figure 1) produced a gradient of 63 ± 15 (mg ferritin). (g dry liver tissue)/(mg Fe)/(L serum) and an intercept of 509 ± 157 mg ferritin/L (r^2=0.36). The ROC curve analysis (Table 1) indicated that, in this cohort, a SF cut-off of 1270 mg /L potentially has good sensitivity and specificity for predicting a LIC above 15 mg Fe/g and a SF cut-off of 1076 mg /L has poor diagnostic performance for predicting a LIC above 7 mg Fe/g.

Table 1. ROC Curve Analysis.

LIC threshold (mg Fe/g dw)	SF (mg /L)	Sensitivity (95% CI)	Specificity (95% CI)	AUC (SE)
> 7	1076	0.68 (0.43 – 0.87)	0.93 (0.68 -1.00)	0.82 (0.07)
> 15	1270	1.00 (0.48 – 1.00)	0.90 (0.73 – 0.98)	0.92 (0.05)

AUC, area under the receiver operating characteristic curve.

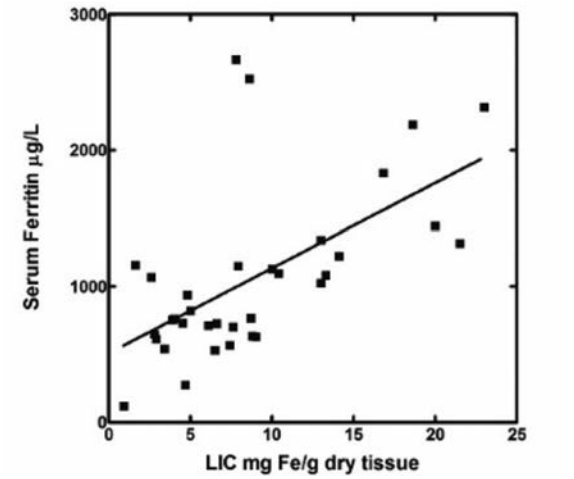

Figure 1.

Summary/Conclusions: In this study of pediatric cancer survivors, the gradient between SF and LIC and the SF cutoffs identified for predicting clinically important LIC values are considerably lower than observed for thalassemia or adult HSCT patients. This difference in the relationship between SF and LIC for different patient and age groups highlights the difficulty in relying on SF to screen for and define iron overload.

P293

DECREASED MCP-1 LEVELS IN PATIENTS WITH HEREDITARY HEMORRHAGIC TELANGIECTASIA: A CYTOKINE SIGNATURE OF IRON DEFICIENCY

G. Porto[1,*], M. Coutinho[2], L. Costa[2], C. Moreira[2], J. Coutinho[2], R. van Swelm[3], D. Swinkles[3], M. Muckenthaller[4], M. Lawless[5]
[1]Basic & Clinical research on Iron Biology, I3S, Instituto de Investigação e Inovação em Saúde, [2]Clinical Hematology, Centro Hospitalar do Porto - Hospital santo António, Porto, Portugal, [3]Laboratory Medicine, Radboud University Medical Center, Nijmegen, Netherlands, [4]Molecular Medicine Partnership Unit, European Molecular Biology Laboratory and University of Heidelberg, Heidelberg, Germany, [5]Experimental Medicine, UCD School of Medicine, Mater Misericordiae University Hospital, Dublin, Ireland

Background: Sustained iron deficiency is a major determinant of erythropoietin (Epo) resistance and consequent persistence of anemia in severely affected Hereditary Hemorrhagic Telangiectasia (HHT) patients with uncontrolled chronic bleeding. The mechanisms underlying erythroid suppression in these cases are still not fully understood.
Aims: We sought to investigate the potential impact of pro-inflammatory cytokines on the erythroid suppression associated with extreme iron deficient in HHT patients, focusing on MCP-1, recently described as a negative regulator of cellular iron uptake.
Methods: the study includes 18 HHT patients, 9 males and 9 females, aged 32-79 years , followed at the Hematology Service of CHP-HAS from 2013 to 2017. They all had history of persistent epistaxis (with variable frequency and severity) with or without gastrointestinal bleeding. The most severe cases (n=6) were resistant to iron treatment being transfusion dependent. Blood samples were collected in all cases for determination of erythroid parameters (including reticulocyte counts, Epo and soluble transferrin receptors (sTfR) levels) iron parameters (transferrin saturation, serum ferritin and hepcidin) and a cytokine profile (GM-CSF, IFN-γ, IL-10, Il-15, IL-1β, IL6, TNF-α, IP-10 and MCP1). The same parameters were determined in a group of 16 patients (5 males and 11 females aged 31-81 years) with iron deficiency (ID) due to chronic gastrointestinal bleeding under intravenous iron treatment and in a control group of 21 apparently healthy blood donors (9 males and 12 females aged 39-62 years). Magnetic Resonance Imaging (MRI) was used to assess tissue iron stores in liver, spleen and bone marrow.
Results: Severe anemia with absolute iron deficient (confirmed by appropriate hepcidin downregulation and absence of bone marrow iron stores by MRI) was evident in transfusion dependent HHT patients (TDHHT). Epo resistance in these cases was evidenced by an exponential increase of Epo levels correlated with parameters of severe anemia and ID with highly increased sTfR but inappropriate reticulocyte counts. Significantly decreased MCP-1 levels were observed in TDHHT patients but also in the other iron deficient groups. No significant alterations were observed in other cytokines except for IP-10 which was also decreased in TDHHT patients. In general, there is a linear decrease of MCP-1 with decreasing Hgb and increasing Epo levels. This effect, however, seems to be "blunted" in severely anemic TDHHT patients with Epo levels above 200 UI/L.
Summary/Conclusions: What is the sensing pathway downregulating MCP-1, and whether an insufficient MCP-1 downregulation contributes to Epo resistance and persistence of severe anemia in TDHHT patients, these are pending questions deserving further investigation.

P294

FERRIC CARBOXYMALTOSE VERSUS IRON SUCROSE COMPLEX IN WOMEN WITH IRON DEFICIENCY ANEMIA – A RANDOMISED CONTROLLED TRIAL

G. Chaudhry[1,*]
[1]Obstetrics & Gynaecology, SBAMI, New Delhi, India

Background: Anemia is a condition in which the number of red blood cells or their oxygen-carrying capacity is insufficient to meet physiologic needs, which vary by age, sex, altitude, smoking, and pregnancy status. The WHO Global Database on Anaemia for 1993–2005, covering almost half the world's population, estimated the prevalence of anaemia worldwide at 25 percent. India falls in 'severe' category of public health significance. Ferric carboxymaltose (FCM) comprises of a macromolecular iron hydroxide complex of polynuclear Fe^{3+} hydroxide tightly bound in a carbohydrate shell. The molecular structure of ferric carboxymaltose ensures controlled delivery of iron within cells of reticuloendothelial system and subsequent delivery to the iron binding proteins fer-

ritin and transferrin, with minimal risk of release of large amounts of ionic iron in the serum.
Aims: To compare safety and efficacy of Ferric Carboxymaltose (FCM) with Iron Sucrose complex (ISC) regarding improvement in haematological parameters and side effects in women with iron deficiency anemia (IDA).
Methods: Prospective randomized controlled study conducted in department of Obstetrics & Gynecology, in a tertiary care hospital in Delhi, India. 60 women having Iron deficiency Anaemia with Hb 6-8 g% were randomized 1:1 into two groups and were given 1000mg parenteral iron. One group received intravenous 500mg Ferric Carboxymaltose on day 0 and 8. 200mg Iron Sucrose complex was given in second group on alternate days for 5 doses. Haematological parameters - Hb. Reticulocyte count, RBC indices, S. ferritin; clinical parameters - fatigue, dyspnoea on exertion and adverse effects were studied on day 0, 7, 14 & 28.
Results: Two FCM infusions *vs* five ISC infusions were required. On day 28 Hb increment ≥3g%seen in 63,33% and MCV>80FL seen in 100% of FCM group *vs* 0%and 43.33% in ISC group. FCM group had 3.17 g/dl increment in Hb *vs* 1.9 g/dl in ISC group. S. Ferritin increased to 147ng/ml in FCM group *vs* 98 ng/ml in ISC group. Significant improvement in RBC indices & rectic count was seen in FCM group. Earlier and significant improvement in fatigability & dyspnoea on exertion was observed in FCM group. Both groups had similar safety profile except for thrombophlebitis was observed in 6.67% FCM group *vs* 50.00% ISC group.
Summary/Conclusions: Intravenous Ferric Carboxymaltose is more effective and safer than Iron Sucrose complex in treatment of Iron deficiency anaemia.

Background: Several susceptibility loci for Hodgkin lymphoma (HL) have been reported, however much of the heritable risk and biological relevance remains unknown.
Aims: To identify novel risk loci for HL and histological subtypes and to further our understanding of how genetic risk loci influence disease susceptibility.
Methods: To our knoweldge, we have performed the largest genome-wide association study of HL totalling 5,156 cases and 16,763 controls across 10 million single nucleotide polymorphisms. We have integrated gene expression, chromatin state, transcription factor (TF) binding and capture Hi-C in model B-cells to functionally annotate new and existing risk loci.
Results: We identified risk loci for all HL at 6q22 (rs9482849, *PTPRK*, P=1.52 × 10^{-8}) and for nodular sclerosis HL (NSHL) at 3q28 (rs4459895, *LPP*, P=9.43 × 10^{-17}), 6q23 (rs6928977, *AHI1*, P=4.62 × 10^{-11}), 10p14 (rs3781093, *GATA3*, P=9.49 × 10^{-13}), 13q34 (rs112998813, *UPF3A*, P=4.58 × 10^{-8}) and 16p13 (rs34972832, *CLEC16A*, P=1.29 × 10^{-8}). Additionally, independent loci within the HLA region were observed for NSHL (rs9269081, HLA-DPB1*03:01, Val86 in HLA-DRB1) and mixed cellularity HL (rs1633096, rs13196329, Val86 in HLA-DRB1). Expression quantitative trait loci were observed in lymphoblastoid cells from 825 individuals at 6q23 (*AHI*, P_{SMR}=8.63x10^{-6}) and10p14(*GATA3*, P_{SMR}=4.70x10^{-8}). Across new and established risk loci we confirmed a significant enrichment of DNase hypersensitivity in GM12878 cells (P=1.20 × 10^{-5}), as well as regulatory elements in primary B-cells (P=6.0 × 10^{-6}) and GM12878 cells (P=6.85 × 10^{-3}). Analysis of ChIP-seq data on 82 transcription factors (TFs) in GM12878 cells, showed an over-representation of the binding of TFs that play a central role in B-cell signalling-networks such as RELA (nuclear factor NF-kappa-B p65), EBF1 (early B-cell factor 1), RUNX3 (runt-related transcription factor 3) and BATF (basic leucine zipper transcription factor, ATF-like).
Summary/Conclusions: These observations support the assertion that risk loci for HL mediate their effects through B-cell developmental networks, and are involved in transcriptional initiation and enhancement. Furthermore, our findings emphasise the differences between the major subtypes, which are likely reflective of differences in disease aetiology.

SOX11 PROMOTES TUMOR PROTECTIVE MICROENVIRONMENT INTERACTIONS IN MANTLE CELL LYMPHOMA

P. Balsas[1,*], J. Palomero[1], Á. Eguileor[1], M.L. Rodriguez[2], M.C. Vegliante[1], E. Planas-Rigol[3], M.C. Cid[3], E. Campo[4], V. Amador[1]
[1]Human and experimental functional oncomorphology, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), [2]Human and experimental functional oncomorphology, IDIBAPS, [3]Vasculitis Research Unit, Department of Autoimmune Diseases, IDIBAPS, Hospital Clínic, University of Barcelona, [4]Human and experimental functional oncomorphology, Department of Anatomic Pathology, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Hospital Clinic, University of Barcelona, Barcelona, Spain
Background: Mantle Cell lymphoma (MCL) is one of the most aggressive lym-

phoid neoplasms characterized by highly infiltrated tumor cells in lymphoid tissues and extra nodal sites. The patients have short responses to current therapies and frequent relapses. However, recent studies have identified a subset of MCL with indolent clinical behavior that tends to present with leukemic disease instead of extensive nodal infiltration, and that is characterized by the absence of the transcription factor SOX11 [SRY (*Sex determining region-Y)-box11*]. However, SOX11 oncogenic pathways driven MCL tumor progression are poorly known.
Aims: The goal of our study was to identify the spectrum of genes regulated by SOX11 in malignant lymphoid cells and provide insights on how the constitutive overexpression of SOX11 may contribute to the oncogenic development of MCL.
Methods: We first generated a stable transduced SOX11-silenced MCL cell line with reduced SOX11 protein levels by infecting MCL cell lines with lentiviral particles carrying shRNA plasmids specifically targeting SOX11. SOX11-positive MCL cell line was infected with the empty vector and used as a control. These two MCL cell lines were injected in two different mice models to analyze *in vivo* the tumorigenic potential of SOX11, subcutaneous (sc) and intravenous (iv) xenograft tumor models. To analyze the crosstalk between MCL and microenvironment, we did *in vitro* cocultures experiments using accessory cells at the tumor microenvironment, as endothelial and bone marrow mesenchymal cells.
Results: In the sc mice model, we observed that SOX11 silencing reduced tumor growth compared to SOX11-positive control tumors. We analyzed the gene expression profiling of these xenograft tumors and of SOX11-positive and negative primary cases and we observed than different microenvironment-related signatures were enriched in SOX11-positive compared with SOX11-negative cells, as angiogenesis, migration and stromal stimulation. By ChIP-chip data, we observed than SOX11 is regulating transcription of different genes involved in these signatures, between them PDGFA. This data indicated a role for SOX11 in the crosstalk of MCL with tumor microenvironment. We found that SOX11 promotes angiogenesis in MCL cells through PDGFA regulation, promoting tumor growth and vasculature. Inhibition of PDGFA on endothelial cells impaired SOX11-enforced angiogenesis in MCL, and the treatment of SCID mice with a PDGFA inhibitor reduced tumor growth and angiogenesis of SOX11-positive MCL xenograft tumors. We also observed that SOX11 promotes migration, pseudoemperipolesis (migration of tumor cells beneath stromal cells) and cell adhesion mediated-drug resistance (CAM-DR) in MCL cells, increasing their survival and proliferation, and that these mechanisms were reduced in SOX11-negative cells. In the iv mice model, we observed that SOX11-positive cells were able to migrated and infiltrated bone marrow and lymph nodes, whereas SOX11-negative cells were retained in peripheral blood.
Summary/Conclusions: In conclusion, our results show that SOX11 is regulating essential processes involved in aggressiveness of MCL tumor cells, as angiogenesis, invasion and drug resistance. Inhibition of SOX11-target genes may represent an efficient strategy for the treatment of aggressive MCL.

AICDA DRIVES EPIGENETIC HETEROGENEITY IN GERMINAL CENTER-DERIVED LYMPHOMAS AND ACCELERATES LYMPHOMAGENESIS

P.M. Dominguez [1,*], M. Teater[2], D. Redmond[2], Z. Chen[2], D. Ennishi[3], D.W. Scott[3], L. Cimmino[4], P. Ghione[2], J. Chaudhuri[5], R.D. Gascoyne[3], I. Aifantis[4], G. Inghirami[2], O. Elemento[2], A. Melnick[2], R. Shaknovich[6]
[1]Department of Medicine, [2]Weill Cornell Medicine, New York, United States, [3]British Columbia Cancer Agency, Vancouver, Canada, [4]NYU School of Medicine, [5]Memorial Sloan-Kettering Cancer Center, New York, [6]Cancer Genetics, Inc, New Jersey, United States

Background: Diffuse large B-cell lymphomas (DLBCLs) are aggressive tumors derived from germinal center (GC) or post-GC B cells. Previous work from our group established that inferior outcome in DLBCL is associated with higher degrees of intra-tumor and inter-tumor cytosine methylation heterogeneity, although the molecules driving this epigenetic perturbation remain unknown.
Aims: We investigated the contribution of activation-induced cytidine deaminase (AICDA) to cytosine methylation heterogeneity in DLBCLs. AICDA is highly expressed in GC B cells where it drives somatic hypermutation (SHM) and also mediates DNA hypomethylation and epigenetic heterogeneity. AICDA is also expressed in a subset of DLBCLs and high level of AICDA in CHOP-treated DLBCL patients is associated with unfavorable prognosis. Thus, we hypothesized that AICDA could contribute to a more aggressive behavior of DLBCLs by facilitating epigenetic plasticity through the redistribution of cytosine methylation. We propose: AIM1. To characterize the effects of AICDA on the methylome and transcriptome of neoplastic B cells. AIM2. To determine the contribution of AICDA-mediated epigenetic modifications to DLBCL pathogenesis.
Methods: We overexpressed AICDA in bone marrow cells from VavP-*Bcl2* transgenic mice, which develop B cell lymphomas of GC origin. We transplanted AICDA-overexpressing (VavP-*Bcl2*+*Aicda*) or control (VavP-*Bcl2*) cells into lethally irradiated recipients. We studied survival, characterized disease biology and analyzed epigenome, genome and transcriptome of lymphomas. In addition, we studied GC B-cells from WT and *Aicda*$^{-/-}$ mice and analyzed the epigenome of primary DLBCLs samples, classified as AICDA^{high} and AICDA^{low} cases according to their AICDA expression.
Results: We observed more aggressive lymphoma phenotype in VavP-*Bcl2*+*Aicda* mice (n=7) compared to VavP-*Bcl2* mice (n=6), based on greater disruption of the splenic architecture and higher degree of B cell infiltration in organs such as lung, liver and kidney. Notably, the overexpression of AICDA reduced significantly the lifespan of the mice (Log-rank test p=0.0289). Neoplastic B cells from VavP-*Bcl2*+*Aicda* (n=4) and VavP-*Bcl2* (n=4) mice displayed similar mutation and indel burdens, suggesting that the more aggressive phenotype of AICDA-overexpressing mice was not likely due to increased mutagenesis. We profiled then the DNA methylation landscape of neoplastic B cells from VavP-*Bcl2*+*Aicda* and VavP-*Bcl2* mice. A principal component analysis of all CpGs, represented by its mean DNA methylation and heterogeneity (interquartile range) differences across replicates, revealed methylation loss and increased intertumor heterogeneity within VavP-*Bcl2*+*Aicda* methylomes compared to VavP-*Bcl2* (49,750 AICDA-perturbed CpGs). These altered CpGs were depleted in promoters and enriched in introns and intergenic regions. We observed a remarkably similar pattern of focal heterogeneity and demethylation in primary DLBCLs with high AICDA compared to low AICDA expression (37,557 AICDA-perturbed CpGs); and a reciprocal pattern of gain of methylation and reduced methylation heterogeneity in *Aicda*$^{-/-}$ compared to *Aicda*$^{+/+}$ GC B cells (64,323 AICDA-perturbed CpGs), suggesting a conserved epigenetic function of AICDA in GC B cells and human and mouse GC-derived lymphomas. Finally, we found significant overlap between genes affected by AICDA-perturbed CpGs in human AICDA high DLBCLs and murine VavP-*Bcl2*+AICDA lymphomas (P=2.21e-23) and with the genes affected by AICDA in GC B-cells (P=8.48e-33).
Summary/Conclusions: Our results demonstrate that AICDA acts as a methylome modifier in GC-derived lymphomas, introducing epigenetic heterogeneity, which may provide tumor cells with higher capacity to adapt to an evolving environment. These findings are relevant not only for B-cell lymphomas, but also for other types of cancer expressing cytosine deaminases.

XPO1 INHIBITION SYNERGIZES WITH BCR INHIBITION, BLOCKS TUMOR GROWTH AND PROLONGS SURVIVAL IN A BIOLUMINESCENT ANIMAL MODEL OF PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA

M. Crespo[1,*], I. Jiménez[1], J. Carabia[1], S. Bobillo[2], P. Abrisqueta[2], C. Palacio[2], C.D.C. Carpio[2], J. Castellvi[3], J. Seoane[4], F. Bosch[1]
[1]Experimental Hematology, [2]Hematology, Vall d'Hebron Institute of Oncology, [3]Pathology, Vall d'Hebron Research Institute, [4] Gene Expression and Cancer Laboratory, Vall d'Hebron Institute of Oncology, Barcelona, Spain

Background: Primary central nervous system lymphoma (PCNSL) is an non-Hodgkin lymphoma localized in the CNS. Approximately 95% of PCNSL are classified as diffuse large B-cell lymphoma (DLBCL), being most of them related to activated B-cell type (ABC-DLBCL). PCNSL is associated with poor prognosis, particularly because of the difficulty for drugs to cross the blood brain barrier. High dose methotrexate is the most effective treatment, but relapse is very common and salvage treatment options are scarce. Also, in patients with systemic lymphoma, the secondary infiltration of the CNS is a fatal event, with a global overall survival of less than six months. Therefore, the development of new drugs with ability to penetrate the CNS is highly needed. Selinexor (KPT-330) is a Selective Inhibitor of Nuclear Export (SINE) that inactivates XPO-1 protein and induces anti-tumor effects mainly due to forcing nuclear retention and activation of tumor suppressors. Selinexor has shown excellent brain penetrance and promising results in pre-clinical models of glioblastoma and can inhibit both BCR and NF-kB signaling in malignant B-cells.
Aims: In order to provide a pre-clinical rationale for the design of new therapies for patients with CNS lymphoma our main aim is to assess the role of XPO-1 inhibition in intracerebral xenograft murine models.
Methods: We *in vitro* tested the sensitivity of DLBCL cell lines to selinexor and ibrutinib by MTS and AnnexinV/PI assay. We established an orthotopic xenograft model of PCNSL by stereotactic injection of OCI-Ly10 (ABC, MYD8 and CD79b mut) cells expressing luciferase into the cerebral parenchyma of nude athymic mice. We longitudinally quantified intracerebral tumoral growth by bioluminescence detection.
Results: To compare the sensitivity of DLBCL cell lines to selinexor we determined the IC50 in terms of survival and proliferation in 4 ABC and 5 GCB DLBCL cell lines. DLBCL cell lines had equivalent sensitivity to selinexor, regardless cell of origin (COO). In detail, survival by AnnexinV-PI exclusion showed that mean ID50 for ABC cell lines was 4.98 μM +/- 3.6 and 6.3 μM +/- 3.8 for GCB (p=0.9). Proliferation by MTS was also blocked by selinexor (mean ID50 for ABC-DLBCL was 1.35 μM +/- 0.7 *vs* 16.16 μM +/- 11.17 for GCB-DLBCL (p=0.41)). Since SINE compounds have been shown to inhibit the BCR, we next tested the potential synergy between ibrutinib and selinexor. In 3 out of 4 ABC-DLBCL cell lines there was a strong synergy. In contrast, none of the 3 GCB-DLBCL cell lines analyzed were sensitive to up to 100 μM ibrutinib; interestingly, however, treatment with selinexor sensitized SUDHL4 cells to ibrutinib and showed strong synergism between the two drugs. Finally, we established an orthotopic xenograft model of PCNSL by stereotactic injection of OCI-Ly10 cells expressing luciferase into the cerebral parenchyma of nude athymic mice. Eleven days after the injection of cells all animals had developed detectable tumors confined to the CNS. Tumor size

was measured and animals were randomly distributed into drug or vehicle group. At this time point mice were treated with 5mg/kg of selinexor or vehicle via oral gavage three times a week; subsequently, bioluminiscence was assessed twice a week. Treatment with selinexor significantly increased mice survival, with a median survival of 48 days in the treatment group compared to 34 days in the vehicle group ($p<0.0001$; Figure 1A). Mice in the treatment group showed a significantly slower increase in tumor size (two-way ANOVA: $p<0.0001$; Figure 1B). Specific time-point analysis showed that differences were significant as soon as 8 days after treatment. At final point, histopathological analysis showed diffuse infiltration in meninges and cerebral parenquima of highly proliferative CD20-positive B-cells. Currently, we are evaluating the synergy between ibrutinib and selinexor *in vivo*. For that we have used the same experimental setting and assigned 12 mice to each of the following groups: selinexor only (5mg/kg three times a week via oral gavage), ibrutinib only (25mg/kg daily in drinking water), combination or vehicle. Results will be available at the time of the meeting.

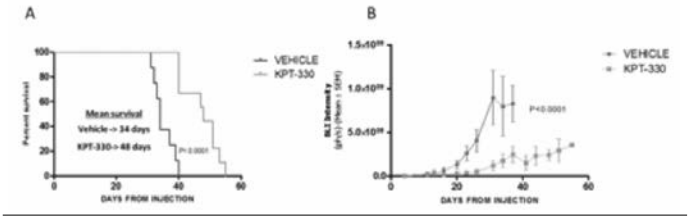

Figure 1.

Summary/Conclusions: Selinexor inhibits proliferation and survival of DLBCL cell lines regardless of COO and it can synergize with ibrutinib. Treatment of mice with CNS confined ABC-DLBCL with selinexor significantly reduces tumor growth and increases survival. Our results provide pre-clinical evidence for the development of selinexor as new therapeutic option for PCNSL or DLBCL with CNS involvement.

MOLECULAR HETEROGENEITY IN PERIPHERAL T-CELL LYMPHOMA NOT OTHERWISE SPECIFIED REVEALED BY COMPREHENSIVE MUTATIONAL PROFILING

Y. Watatani[1,*], Y. Sato[2], K. Nishida[2], H. Miyoshi[3], Y. Shiraishi[4], K. Chiba[4], H. Tanaka[4], H. Ueno[1], N. Kakiuchi[1], Y. Shiozawa[1], T. Yoshizato[1], K. Yoshida[1], M. Sanada[5], S. Miyano[4], K. Ohshima[3], T. Yoshino[2], S. Ogawa[1], K. Kataoka[1]

Background: Peripheral T-cell lymphomas (PTCLs) are a highly heterogeneous group of mature T-cell neoplasms. In particular, accounting for the majority of PTCL, PTCL-not other specified (PTCL-NOS) is a diagnosis of exclusion and as such, is expected to include many heterogeneous tumors. In fact, recent genetic studies have suggested that a subset of PTLC-NOS is closely related to angioimmunoblastic T-cell lymphoma (AITL); both lymphoma types show follicular helper T-cell (TFH) phenotypes and share mutational targets in common, such as *RHOA*, *TET2*, *DNMT3A*, and *IDH2*. However, with the lack of comprehensive genetic analyses, the molecular pathogenesis is poorly understood in the majority of PTCL-NOS cases.
Aims: The aim of this study is to clarify a landscape of somatic mutations in PTCL-NOS.
Methods: We performed whole-genome/exome and transcriptome sequencing of PTCL-NOS and other related PTCLs, followed by targeted-capture sequencing of candidate drivers in T-cell lymphomas in 100 PTCL-NOS samples.
Results: Consistent with previous reports, *TET2* (38%) was the most frequently mutated gene in PTCL-NOS, followed by *RHOA* (28%), *TP53* (18%), *KMT2C* (13%), *IDH2* (11%), and *PLCG1* (11%). Frequently altered genes included signal transduction molecules (such as *RHOA*, *PLCG1*, *STAT3* and *SOCS1*), chemokine receptors (*CCR4* and *CCR7*), epigenetic modifiers (*TET2*, *KMT2C*, *IDH2*, *DNMT3A*, *CREBBP*, and *KDM6A*), and molecules associated with immune evasion (*HLA-A*, *HLA-B*, *B2M*, and *CD58*). Novel targets of recurrent mutation were also identified, including *PDCD1*, *YTHDF2*, and *LRP1B*, which were frequently targeted by nonsense and frameshift mutations distributed throughout the entire genes. Among these, *PDCD1* encodes PD-1, which transmits an inhibitory signal from PD-L1 and PD-L2 ligands, and therefore loss of function of this gene is predicted to enable malignant T-cells to escape from the negative signaling. By contrast, recurrent mutations in *YTHDF2* and *LRP1B* mutations in T-cell lymphomagenesis is unexpected. These genes encode a reader protein of N6-methyladenosine (*YTHDF2*), and a member of the low density lipoprotein receptor family (*LRP1B*). Although the function of these genes in T-cells are unknown, our findings suggest their unresolved roles, whose dysfunction may lead to malignant T-cell proliferation.Finally, we investigated the co-occurrence between frequently mutated genes in PTCL-NOS. In accordance with previous observation, mutations characteristic of TFH lymphomas (*TET2*, *RHOA*, *IDH2*, and *DNMT3A*) tended to co-occur in a subset of PTCL-NOS cases, but were almost mutually exclusive with mutations in *TP53* and chemokine receptor genes. These observations further support the molecular distinction between TFH and non-TFH lymphomas in PTCL-NOS: the former is more-related to AITL and discriminated from the latter in terms of their mutational profiles.
Summary/Conclusions: In summary, our findings illustrate the landscape of somatic alterations in PTCL-NOS and provide a novel insight into their genetic and molecular heterogeneity, which should help to devise a novel molecular classification of PTCLs and to exploit a new therapeutic strategy to combat these intractable T-cell malignancies.

Background: In the last years, a large body of evidence has been accumulated demonstrating that DNA methylation is not only widely altered in B-cell lymphoid tumors (and cancer in general) but it is also defining cell lineage and maturation stage. However, an integrative study of the whole DNA methylome of neoplastic B cells from different maturation stages has not been performed yet.
Aims: The aim of this study was to extensively dissect the dynamics of DNA methylation in B-cell neoplasias in the light of normal B cell maturation program. The ultimate goal of this study was to generate new clinically relevant knowledge with diagnostic and prognostic value.
Methods: Our dataset included whole-genome bisulfite sequencing data (n=57) and high-density methylation arrays (n=1161) from acute lymphoblastic leukemia (ALL), mantle cell lymphoma (MCL), Burkitt lymphoma (BL), follicular lymphoma (FL), diffuse large B cell lymphoma (DLBCL), chronic lymphocytic leukemia (CLL) and multiple myeloma (MM) patients as well as from ten different normal B cell subpopulations. As DNA methylation estimates in neoplastic samples are influenced both by tumor cell content and composition of the micro environment, we developed a new method to deconvolute and *in silico* purify the methylation signal of tumors arising in different niches (bone marrow, peripheral blood an lymph node). The data were analyzed by a series of bioinformatic and biostatistical approaches and correlated with clinical variables.
Results: The initial bioinformatic approach to purify of DNA methylation signals in B cell tumors revealed that samples with less than 55% tumor cell content could not be accurately purified. This strategy reduced the initial 1,044 tumor samples to 866. An unsupervised principal component analysis of in silico purified data revealed that each type of B-cell neoplasm clusters separately. ALLs clustered closer to precursor B cells, CLL and MCL closer to mature B cells and both DLBCL and MM showed the largest deviation from normal B cells. We then performed a differential methylation analysis comparing each sample *vs* normal B cell maturation stages, and thoroughly annotated the results to biological and clinical features. From the clinical perspective, we identified that for tumor samples with similar cellular origin, the higher the epigenetic deviation from healthy B cells (number of DNA methylation changes) the worse the clinical behavior of the patients. Furthermore, for each tumor entity, we could identify from 5 to 19 epigenetic biomarkers that could classify each entity with high sensitivity and specificity.
Summary/Conclusions: In this study, we show that *in silico* purification of DNA methylation data is a powerful strategy to accurately measure DNA methylation alterations in tumor cells. Using a large dataset, we have developed a set of epigenetic biomarkers with high differential diagnostic power and identified that the epigenetic drift is a universal prognostic factor that can be applied to different B cell tumors.

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a distinct subset of peripheral T-cell lymphoma with follicular helper T-cell (TFH) features. We and others previously found mutations of *RHOA*, encoding p.Gly17Val (G17V RHOA mutation) together with those in an epigenetic regulator, tet methylcytosine dioxygenase 2 in up to 70% of AITL and other TFH lymphoma (a subgroup of peripheral T-cell lymphoma, not otherwise specified (PTCL-NOS)) samples. RHOA, a small GTPase, is converted from the GDP-bound inactive form to the active GTP-bound form by guanine nucleotide exchange factors (GEFs). The G17V RHOA mutant has been shown to be defective in RHOA signaling, because it does not bind GTP. Therefore, it has remained unknown how G17V RHOA is involved in lymphomagnesis. VAV1 serves as an important mediator of T-cell receptor (TCR) signaling pathway through its GEF-dependent and –independent function. VAV1 activation is tightly regulated by autoinhibitory mechanisms in the unstimulated state. Phosphorylation of VAV1 occurs within seconds in response to antigen stimulation of the TCRs by Syk and Src-family tyrosine kinases and initiates downstream TCR signaling.
Aims: We aim at clarifying the downstream signaling of the G17V RHOA mutant in AITL/TFH lymphoma.
Methods: Proteomic screening was performed to identify G17V RHOA-specific binding partners. Binding was validated by co-immunoprecipitation of G17V RHOA and the candidate partners. Simultaneously, RNA sequencing was performed for 9 PTCL samples, including 6 AITL and 3 PTCL-NOS. Targeted deep sequencing of *VAV1* was performed for 126 PTCL samples, including 69 AITL and 57 PTCL-NOS, 37 of which had *RHOA* mutations. The specific binding partner proteins of the G17V RHOA mutant were examined by high throughput screening in Jurkat cells. Nuclear factor of activated T cell (NFAT) activity in response to TCR stimulation was examined in Jurkat cells expressing wild-type (WT) and G17V RHOA mutant, and WT and various VAV1 mutants. Whole transcriptome was compared in Jurkat cells inducibly expressing each cDNA, in conditions with or without TCR stimulation. Expression of phospho-Vav1 was examined by immunostaining for AITL/TFH lymphoma samples.
Results: Proteomic screening identified the VAV1 protein as a G17V RHOA-binding partner. RNA sequencing identified a fusion gene involving *VAV1* and *STAP2* in an AITL sample without RHOA mutations. Moreover, targeted sequencing of *VAV1* identified 2 in-flame deletion mutations in an acidic region (c.C518_529del:p.173_177del and c.C494_520del:p.165_174del) in AITL samples and 2 missense mutations in a zinc finger and SH3-SH2-SH3 module (c.G1668C:p.Glu556Asp and c.C1844T:p.Pro615Leu) in PTCL-NOS and AITL samples, respectively. Phosphorylation of VAV1 at Tyr 174 was enhanced in Jurkat cells expressing the G17V RHOA or VAV1-STAP2 cDNA than those expressing each WT cDNA or mock. Phosphorylation was blocked by the dasatinib at 1-10 nM concentrations. The G17V RHOA, VAV1-STAP2 and various VAV1 mutants enhanced NFAT reporter activities and interleukin-2 (IL-2) mRNA levels compared to their WT or mock in Jurkat cells. Dasatinib completely blocked both of these TCR indicators at the concentration range similar to block VAV1 phosphorylation. Moreover, the aberrant reporter activity was also blocked by the dasatinib treatment. The levels of IL-2 mRNA were higher in Jurkat cells expressing either G17V RHOA or VAV1-STAP2 than those with their WT or mock. Gene set enrichment analysis showed that cytokine and chemokine-related pathways were enriched in Jurkat cells expressing the G17V RHOA compared to those with WT or mock. Finally, phospho-VAV1 was co-stained with PD-1, a TFH marker, in 7 out of 10 PTCL samples with *RHOA* or *VAV1* mutations.
Summary/Conclusions: The G17V RHOA and VAV1 mutants both intensify the TCR pathway through hyper-phosphorylation of Vav1. Our data suggest that the RHOA-VAV1 axis in AITL/TFH lymphoma may contribute to their clinical features and stand as a possible new therapeutic target.

P302

STAT3 IS CONSTITUTIVELY ACTIVATED AND CAN BE A THERAPEUTIC TARGET OF JAK INHIBITORS IN CHRONIC ACTIVE EPSTEIN-BARR VIRUS INFECTION

E. Onozawa[1,2,*], H. Shibayama[1,2], K.-I. Imadome[3], S. Aoki[2], A. Tsuzura[1], T. Koyama[2], O. Miura[1], A. Arai[1]
[1]Department of Hematology, [2]Department of Laboratory Molecular Genetics of Hematology, Tokyo Medical and Dental University, [3]Division of Advanced Medicine for Virus Infections, National Research Institute for Child Health and Development, Tokyo, Japan

Background: Chronic active Epstein-Barr virus infection (CAEBV) is a rare disorder characterized by clonal proliferation of EBV-infected T or NK cells and associated with severe systemic inflammation. Chemotherapy-resistant lymphoma or hemophagocytic lymphohistiocytosis can develop during the course of CAEBV, and the only curative treatment strategy is hematopoietic stem cell transplantation. In addition, why EBV persistently infects T or NK cells and how the disorder develops in patients have not been elucidated yet. The outcome of CAEBV remains poor, and the establishment of an effective chemotherapy based on the molecular mechanisms of CAEBV development is an urgent issue.
Aims: We designed this study to investigate STAT3 activation and its contribution to CAEBV development, because it was recently indicated that STAT3 was constitutively activated in some T- or NK-cell malignancies. We also examined the effects of JAK inhibitors on CAEBV.
Methods: The EBV-positive T- and NK-cell lines SNT8, SNT15, SNT16 and the NK-cell lines SNK1, SNK6, SNK10 were examined. EBV-positive T or NK cells were obtained from peripheral blood mononuclear cells (PBMCs) of CAEBV patients who were diagnosed according to the previously described diagnostic criteria (Blood 2012; 119:673-86). To detect and isolate EBV-infected cells, T and NK cells were separated from PBMCs using magnetic beads. Gene expression was examined using one-color microarray-based analysis (Agilent Technologies, Santa Clara, CA, USA). The direct sequencing analysis of exons 19 to 24 of STAT3, which encode the SH2 domain, was performed using primers from the previous report (N Engl J Med 2012; 366: 1905-13). EBV-negative T- and NK-cell lines and PBMCs from healthy donors were used as negative controls. Cell survival and apoptosis were examined by an XTT assay and Annexin V assay, respectively. The mRNA expression of cytokines was examined by TaqMan® Gene Expression Assays.
Results: STAT3 was constitutively phosphorylated on Y705 and S727 and was localized in the nucleus in EBV-positive T- or NK-cell lines and PBMCs from the CAEBV patients, as indicated by western blotting. The microarray analysis of EBV-positive T or NK cells derived from CAEBV patients demonstrated that the expression of STAT3-responsive genes, including interferon-γ, were upregulated in these cells compared with EBV-negative cells. No mutation was detected in the SH2 domain of STAT3 in patient-derived cells by direct sequencing. The JAK inhibitors ruxolitinib and tofacitinib suppressed STAT3 activation and cell survival by inducing apoptosis of the cell lines and PBMCs from CAEBV patients. Ruxolitinib also inhibited the mRNA expression of TNF-α and interferon-γ in CAEBV patient-derived cells.
Summary/Conclusions: STAT3 is constitutively activated in EBV-positive T or NK cells from CAEBV patients. The inhibition of STAT3 by ruxolitinib could be an attractive and effective treatment for CAEBV by suppressing not only EBV-infected cell survival but also the accompanying inflammation.

P303

RECURRENT MUTATIONS IN MICRO-RNA BINDING SITES MAY BE POTENTIALLY RELEVANT IN FOLLICULAR LYMPHOMA

E. Larrea[1,*], M. Fernandez-Mercado[1,2], I. Ceberio[3], J.A. Guerra Assunção[4], J. Okosun[5], J. Fitzgibbon[6], C. Lawrie[1,7,8]
[1]Molecular Oncology, Biodonostia, [2]Biomedical Engineering, School of Engineering, University of Navarra, [3]Hematology, Hospital Universitario Donostia, Donostia/San Sebastian, Spain, [4]University Collage London, [5]Hematology, [6]Haemato-Oncology, Barts Cancer Institute, London, [7]Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom, [8]Ikerbasque Foundation for Science, Bilbao, Spain

Background: Follicular lymphoma (FL) is the most common low grade B cell malignancy accounting for ~20% of all non-Hodgkin lymphomas. Approximately 30% of the FL cases suffer a histological transformation to a much more aggressive subtype of lymphoma drastically reducing the overall survival from 10 years to just 14 months. Despite being a critical event during disease progression it is molecularly poorly understood and no biomarkers exist to predict this phenomenon. Previous studies have suggested the possibility that deregulation of microRNA expression (miRNAs, small endogenously produced non-coding RNAs) could be implicated in the development of FL disease as well as in the transformation event. We hypothesise that mutations in miRNA binding sites may also have a role in this process.
Aims: We set ourselves to find predictive biomarkers of transformation for FL, with a special focus on sequence variants affecting miRNA binding sites.
Methods: We interrogated whole genome sequencing (WGS HiSeq, Illumina) data from sequentially obtained samples of 6 FL patients that underwent trans-

formation using a bespoke bioinformatic pipeline based on TargetScan prediction algorithm in order to identify mutations in putative miRNA binding sites. Once identified, in order to validate them and test their recurrence in an extended cohort (60 samples from 31 FL patients who underwent transformation plus 21 samples of non-transformed FL patients) we designed an Ampliseq (Ion Torrent, Life Technologies) NGS custom panel. Finally, we selected a number of variants for assessing the variant effect on the miRNA:mRNA interaction, by means of a combination of an *in silico* predictive algorithm and *in vitro* luciferase assays.

Results: 36% of somatic variants from WGS data arose in 3´UTR, and 68% of these were putative miRNA-binding sites (525 mutations in 497 genes). Interestingly, the ontogeny analysis showed that these mutations were not randomly distributed but rather there was enrichment in genes associated with haematological malignances ($P=2.18x10^{-4}$).We then validated 85% of these mutations using targeted resequencing and found a total of 103 recurrent variants located in putative miRNA binding sites. QC criteria filtering led us to prioritise 38 variants in 25 genes to be functionally tested. Crucially, ontogeny analysis showed that these genes were highly enriched for GC-like B-cell lymphoma genes ($P=4.39x10^{-5}$), strongly suggesting that these variants may have a biological significance in the disease. We then performed an *in silico* approach based on TargetScan miRNA target prediction algorithm to evaluate the effect of the mutations on the binding of the miRNAs to their target sites. Based on these results we prioritized some of these genes to perform luciferase assays. We experimentally demonstrated not only that the majority of these *loci* are *bona fide* miRNA targets sites, but also that the presence of a number of these variants cause a dysregulation of the normal miRNA regulatory activity (Figure 1).

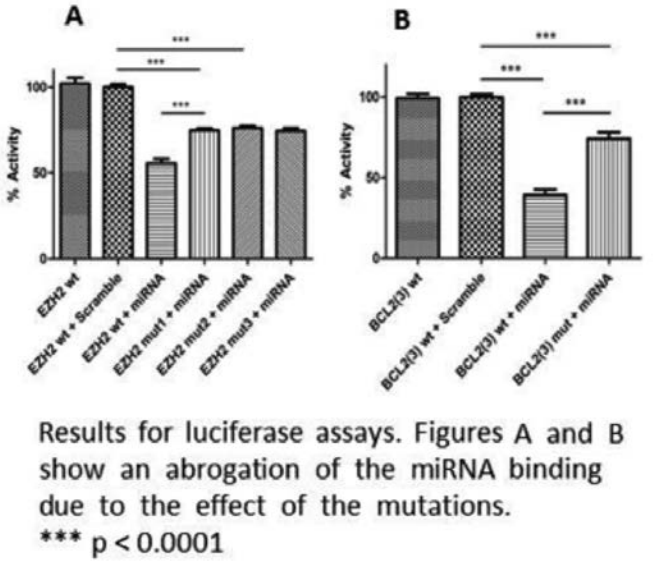

Figure 1.

Summary/Conclusions: Our data show that the identified mutations do not occur randomly, but preferentially in putative microRNA binding sites of genes related to lymphomagenesis, supporting their role in FL pathogenesis. Furthermore, the presence of some of the identified variants in miRNA binding sites indeed promotes a dysregulation of the normal miRNA regulatory activity, suggesting that they might have a biological significance in FL.

P304

CLINICAL IMPACT OF TP53 AND KMT2D MUTATIONS IN MCL RECEIVING HIGH-DOSE THERAPY AND AUTOLOGOUS TRANSPLANTATION: UPDATED RESULTS FROM THE FONDAZIONE ITALIANA LINFOMI MCL0208 PHASE III TRIAL

Background: Within the landscape of mutated genes in mantle cell lymphoma (MCL), only *TP53* disruption has been so far associated with outcome.

Aims: Here we present the clinical update of the deep sequencing MCL gene panel analysis in the prospective FIL-MCL0208 phase III trial (NCT02354313, high-dose immunochemotherapy followed by autologous transplantation for untreated, advanced stage <65 years MCL) based on the data from the second interim analysis.

Methods: A targeted resequencing gene panel, including coding exons and splice sites of the *ATM*, *BIRC3*, *CCND1*, *KMT2D*, *TP53*, *TRAF2*, *WHSC1*, and *NOTCH1* genes was analyzed in tumor DNA from baseline bone marrow CD19+ purified MCL cells and, to filter out polymorphisms, in the paired normal genomic DNA (55% of cases) using a TruSeq Custom Amplicon target enrichment system followed by deep next generation sequencing (Illumina, median depth of coverage 2356x). Variants represented in >10% of the alleles were called with VarScan2 with the somatic function when the paired germline DNA was available. For patients lacking germline DNA, a bioinformatics pipeline including a number of stringent filters was applied to protect against the misclassification of polymorphisms as somatic variants. Clinical data were updated at the time of the second interim analysis (January, 2017).

Results: Out of the 300 enrolled patients, 174 were evaluable for mutations. Median follow-up of the cohort was 36 months, and 3-years PFS and OS were 67% and 86%, respectively. Patients not included in the study, due to unavailable tumor DNA (n=126) showed superimposable clinical features and outcome. Mutations of *TP53* (8% of cases) and *KMT2D* (11% of cases) associated with an increase in the hazard of progression both in univariate analysis as well as after adjusting for MIPI, Ki67 and blastoid variant: HR 3.87 (95% CI 1.64 to 9.13), p<0.002 and HR 3.66 (95% CI 1.77 to 7.56), p<0.001, respectively. These results translated into an increase of the hazard of death in both *TP53* and *KMT2D* mutated patients both in univariate analysis as well as adjusting for MIPI, Ki67 and blastoid variant HR 4.26 (95% CI 1.34 to 13.57), p=0.014 and HR 3.09 (95% CI 1.07 to 8.86), p=0.036, respectively. On these bases, a survival model was proposed based on the *TP53* and *KMT2D* mutation status: 3-years PFS and OS were 26% and 64% for patients carrying either *TP53* or *KMT2D* mutations or both *vs* 75% and 92% for patients without any of these mutations (Figure 1).

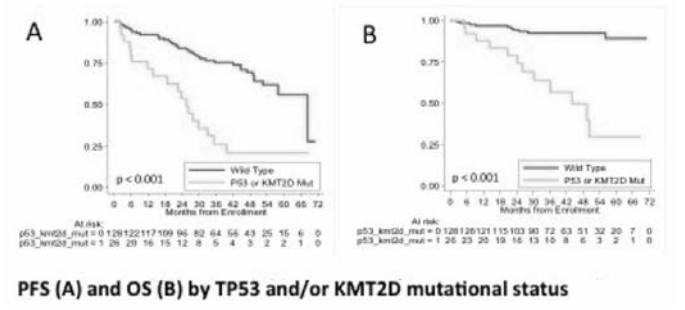

Figure 1.

Summary/Conclusions: The updated clinical results of the FIL-MCL0208 trial show that: i) both *TP53* and *KMT2D* mutations independently associate with shorter PFS and OS in younger MCL patients receiving high-dose therapy; ii) *KMT2D* mutations seem to be as detrimental as *TP53* mutations, at least in terms of PFS; iii) given the negative prognostic impact of these mutations, they might be used to select high-risk patients for novel therapeutic approaches.

Multifaced aspects of bleeding disorders

P305

A LOOKBACK AT VWD TYPE 2A AND 2M CLASSIFICATION IN A LARGE COMPREHENSIVE HAEMOPHILIA CENTRE.

S. Jaafar[1,2,*], T.T. yee[1]
[1]Haematology, Royal Free Hospital /NHS, [2]Haematology, katharine dormandy haemophilia centre/royal free hospital, london, United Kingdom

Background: Von Willebrand Disorder (VWD) has a prevalence of approximately 1% in the general population and is due to quantitative deficiencies or qualitative defects of the Von Willebrand Factor (VWF) protein. VWF is a large meltimeric protein with multiple functions. It carries and protects factor VIII and helps in the binding of FVIII, platelets and the vascular endothelium at sites of injury. VWF binding to platelets is through several receptors most notably the glycoprotein 1b (GP1b) and collagen exposed at site of injury is important for VWF adhesion to the subendothelial matrix forming an adhesive anchor. Classification of VWD is based on the quantitative deficiencies (Type 1 and 3) and VWD type 2 are qualitative defects of the VWF protein with or without quantitative deficiency as well. Type 2 VWD is further subdivided into type 2A,2B,2M and 2N. These subtypes depend on a number of laboratory assays that measure the FVIII activity, VWF protein level (VWFAg assay) and the function of the protein i.e its ability to bind to 1) FVIII(FVIII - VWF binding assays),2) platelets (VWF ricof assay) and 3) collagen (VWFCB assay). Other tests include ristocetin induced platelet aggregation (RIPA), multimer analysis, assay ratios and VWF genetic analysis. No single commercially available laboratory method can achieve to test all the parameters required to clinch the accurate diagnosis of the subtypes of VWD. Use of those multiple assays with VWF ricof/VWFAg ratio, VWF CB (VWF-CB)/ (VWF Ag) ratio have helped in the better identification of VWD and the subtypes.
Aims: To assess recent various VWF investigation panels and assay ratios, VWF genetic analysis, multimeric patterns of the VWF protein in accurate diagnosis of the VWD subtypes. VWD 2A and 2M shows similarities in certain aspects and it is important to differentiate these 2 subtypes as new therapies become available and personalised treatment approaches of VWD become a reality.
Methods: Clinicians who have made a diagnosis of VWD for individuals referred for a bleeding state work up would classify the subtypes of the VWD according to the results of the investigations available at the time of seeing the patients. All patients with an inherited bleeding disorder would then be registered in the centre and details would be put into a database. We have looked back into the database from the period of 2000 to end of 2016 and focussed on the VWD types 2A and 2M. Current VWD diagnostic panel in our centre includes the following tests: FVIII one stage assay, VWFAg Elisa,VWF ricof; Platelet agglutination method, VWF CB Elisa methods, VWF multimeric analysis by gel chromatography and VWF exon 27/28 genetic mutations are routinely done. New information and new set of results for the registered patients have been taken into account the classification of VWD type 2A and 2M and the database are updated.
Results: In the VWD database 38 patients classified as 2M and 19 patients as type2A have been recorded from 2000 to end of 2016. With the updated results and genetic analysis and the response to DDAVP, around 30% of the patients have had their subtypes changed. This exercise confirms that no singular test can be used to accurately diagnose the VWD and its subtypes and illustrates the importance of DDAVP testing and the difficulty of interpreting assay ratios for subtyping when VWFricof levels are <15u/dl.
Summary/Conclusions: VWD may be misdiagnosed, underdiagnosed or overdiagnosed. Appropriate and complete investigative panel is necessary for complete classification of VWD and its subtypes.

P306

RETROSPECTIVE EVALUATION OF PHENOTYPE AND MANAGEMENT OF DYSFIBRINOGENEMIA AND HYPODYSFIBRINOGENEMIA IN A COHORT OF ITALIAN PATIENTS

C. Santoro[1,*], F. Massaro[1], E. Baldacci[1], G. Ferrara[1], F. Malaspina[1], R.C. Santoro[2], S. Pasca[3], G. Castaman[4], F. Peyvandi[5], R. Foà[1], M.G. Mazzucconi[1]
[1]Cellular Biotechnology and Hematology, Hematology Sapienza University, Rome, [2]Oncohaematology Department, Haemostasis and Thrombosis Service- Pugliese-Ciaccio Hospital, Catanzaro, [3]Center for Hemorrhagic and Thrombotic Diseases, University Hospital of Udine, Udine, [4]Center for Bleeding Disorders, Careggi University Hospital, Florence, Florence, [5]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy

Background: Dysfibrinogenemia (DF) and hypodysfibrinogenemia (HDF) patients (pts) experience hemorrhages or thromboses, and the clinical management can be difficult.
Aims: Aim of this study is to obtain information on DF/HDF clinical phenotype and management.
Methods: This is a spontaneous, retrospective, multicenter national study. Data are collected from clinical records.
Results: Forty-one pts have been enrolled in 3 centers: 35 DF (85%), 6 HDF (15%); 18M, 23F. Median follow-up: 7.4 months (1-203). Median age at diagnosis: 36 years (range 3-81). Median fibrinogen activity/antigen level: 53 mg/dL (0-156) and 250 mg/dL (66-380), respectively. Fourteen pts experienced hemorrhages: epistaxis, hematuria (presence of kidney stones), hematomas, ecchimoses, menometrorrhagia, and gastro-intestinal (presence of esophageal varices). No specific therapy was administered. A portal venous thrombosis occurred in 1 DF splenectomized patient in absence of replacement therapy; he was treated with warfarin without anti-hemorrhagic prophylaxis. Forty-one minor/major surgeries were performed in 23 pts. In 10/41 (24%) cases, prophylaxis was administered [fresh frozen plasma in 3, fibrinogen concentrate (FC) in 1, tranexamic acid in 6]; in 5/41 (12%) cases, low molecular weight heparin (LMWH) was administered; no hemorrhage occurred. Thirteen pregnancies were initiated in 9 women. In 1 case, LMWH prophylaxis was administered during pregnancy, and in 1 other during puerperium. In 2 cases, FC was administered at the time of spontaneous delivery (SD). Nine SD and 4 cesarian sections were performed without complications.
Summary/Conclusions: Pts from this case series experienced few hemorrhagic/thrombotic events. The majority was asymptomatic and the most severe events were related to concomitant pathologies. Nonetheless, this study has the potential to collect data from a numerous population of pts who live in the same country, and therefore to provide useful information to better characterize and manage these rare diseases. .

P307

OSTEOPOROSIS IN PATIENTS WITH HEMOPHILIA

V. Zorenko[1,*], T. Polyanskaya[1], E. Karpov[1], A. Kovrigina[1], T. Tupoleva[1], A. Golobokov[1], N. Sadykova[1], G. Mishin[1], M. Sampiev[1], D. Vasiliev[1], D. Petrovskii[1], A. Koroleva[1]
[1]National Research Center for Hematology, Moscow, Russian Federation

Background: Osteoporosis is often a co-morbidity of hemophilia, which exacerbates the hemophilic arthropathy and affects the long-term stability of the components after the arthroplasty. We present our results for the presence of osteoporosis in 148 patients with haemophilia and hemophilic arthropathy.
Aims: To prevent progression of hemophilic arthropathy and increase the long-term stability of the components after the arthroplasty.
Methods: . In the period from 2015 to 2016. the presence of osteoporosis surveyed 148 patients with haemophilia who are hospitalized in the department of reconstructive orthopedics for patients with hemophilia (Moscow, Russia): 121 (81.8%) - hemophilia A, 21 (14.2%) - and hemophilia B 6 (4%) – haemophilia with inhibitor. The average age of the patients was 39.3 years (range 10 to 69 years). 121 patients with hemophilic arthropathy performed primary total arthroplasty (98 knee, 20 hip, 3 shoulder joints); 18 patients underwent revision arthroplasty (5 - purulent infection, 7 - instability of the implants, 4 - fractures, 2 - loss of motion in the operated joint). 40 patients underwent ultrasound densitometry.
Results: As a result of ultrasound densitometry in 17.5% (7 patients) of cases revealed osteopenia and 20% (8) T-highest index. 105 patients underwent histological study in which 93 (88.6%) bone resorption, 58 (55.2%) intraosseous hemorrhage which 53 (50,5%) cases were accompanied by bone resorption. In total (histologically and of ultrasound densitometry) 99(66.9%) patients with haemophilia had osteopenia.
Summary/Conclusions: The data indicate that osteoporosis at patients with haemophilia considerably more common than in the general population. Intraosseous hemorrhage identified in more than half of the cases, exacerbate the decline in bone mineral density.

P308

PREVALENCE OF GENETIC MARKERS OF OXIDATIVE STRESS IN PATIENTS WITH SEVERE HEMOPHILIA FROM NORTH-WESTERN RUSSIA

S. Kapustin[1,*], L. Aleksanyan[1], L. Rybakova[1], V. Kargin[2], V. Burakov[2], S. Svitina[1], A. Titov[2], V. Soldatenkov[2], A. Chechetkin[3]
[1]Laboratory of Biochemistry, [2]Surgery Department, [3]Russian Research Institute Of Haematology And Transfusiology, Saint-Petersburg, Russian Federation

Background: Severe haemophilia (SH) is often complicated by chronic arthropathy due to recurrent haemorrhagic events and activation of such biological mechanisms as oxidative stress (OS) and inflammation. We have previously shown that the biochemical markers of OS and/or deficiency of antioxidant system (AOS) are frequently seen in SH patients affected with joint(s) destruction. Until now, there is a little data on the frequency of genetic variants predisposing to OS or decreased AOS activity in patients with SH.
Aims: To assess the prevalence of several genetic variants predisposing to OS or decreased AOS activity in patients with SH from North-Western Russia (NWR).
Methods: We studied 71 men with severe haemophilia A or B (62 and 9 patients, respectively). Osteoarthritis of large joint(s) was detected in each

patient, with the rate of recurrent haemorrhagic events in joint(s) from 6 to 13 per year. The control group consisted of 255 age-matched healthy men. Gene polymorphism of apolipoprotein E (ApoE e2/e3/e4), paraoxonase (PON1 Gln192Arg), methylenetetrahydrofolate reductase (MTHFR C677T), catalase (CAT C-262T) and plasmatic glutathione peroxidase (GPX3 T-65C) was studied by PCR-RFLP technique. Statistical differences between the patient and control groups were assessed by Fisher's exact test. Odds ratios (OR) with their 95% confidence intervals (CI) and p-value were calculated by using GraphPad Prism 5.0 software.
Results: We found abnormal distribution of ApoE genotypes in the patient group. Absence of ApoE e3 allele was observed in 7 (9.9%) men with SH and 8 (3.1%) controls (OR=3.4, 95% CI: 1.2-9.7, p=0.025). In particular, the frequency of ApoE e2/e2 genotype was 10-fold increased in patients when compared to healthy men (4.2% *vs* 0.4%, OR=11.2, 95% CI: 1.1-109.5, p=0.034). ApoE e2/e4 and e4/e4 genotypes were also more prevalent in SH than in the control group (2.8% *vs* 0.8% and 2.8% *vs* 2.0%, respectively). In the patient group, we observed the positive association between the PON1 192Gln/Gln variant and heterozygous GPX3 -65TC genotype (OR=5.8, 95% CI: 1.3-25.7, p=0.021). Simultaneous presence of these genetic variants was more than 5-fold frequently found in SH than in controls (8.5% *vs* 1.6%, OR=5.5, 95% CI: 1.3-22.8, p=0.016).
Summary/Conclusions: Our results indicate that OS-provoking variants of ApoE, PON1 and GPX3 genes are frequently seen in SH patients with chronic arthropathy and joint(s) destruction.

P309

THE ROLE OF DNA METHYLATION AND EXPRESSION OF MMP-2 AND MMP-9 IN PATHOGENESIS OF INTRACEREBRAL HEMORRHAGE IN CONGENITAL FACTOR XIII DEFICIENCY

A. Noroozi-Aghideh[1,*], N. Lashgari[2], A. Dorgalaleh[3], Z. Kashanikhatib[4], S. Alizadeh[5]
[1]Hematology and Blood Transfusion, Faculty of Paramedicine, AJA UNIVERSITY OF MEDICAL SCIENCES, [2]MICROBIOLOGY, Faculty of Medicine, AJA UNIVERSITY OF MEDICAL SCIENCES, [3]Hematology and Blood Transfusion, Allied Medical School, Iran University of Medical Sciences, [4]Hematology and Blood Transfusion, High Institute for Education & Research in Transfusion Medicine, [5]Hematology , Allied Medical School, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic Of

Background: Congenital factor XIII deficiency (CFXIIID) is a rare bleeding disorder. Intracerebral hemorrhage (ICH) is a leading cause of mortality and morbidity in this disorder. Matrix metalloproteinase-2 (MMP-2) and MMP-9 are reported to be associated with ICH.
Aims: The purpose of this study was to investigate the association of MMP-2 and MMP-9 methylation and their expression with ICH.
Methods: Patients with abnormal clot solubility test as well as a positive family history of FXIII deficiency were participated in the study. Methylation status was analyzed by Bisulfite Sequencing PCR. Gene expression in mRNA and protein levels was assayed by Quantitative real-time RT-PCR and ELISA, respectively.
Results: We found an unmethylated profile for both MMP-2 and MMP-9 in patients with ICH. Both of these genes were partially methylated in controls. Percent of methylated CGs are also higher for MMP-9 than MMP-2. Higher expression of MMP-9 in both of mRNA and protein levels was found in ICH compared to non-ICH group. However, there were no significant differences in MMP-2 expression levels (neither mRNA nor protein) between two groups.
Summary/Conclusions: Our findings showed that gene methylation contributes effectively in regulation of MMP-9 expression. Furthermore, our data suggest that MMP-2 expression in CFXIIID may not be controlled by gene methylation alone because methylation status of this gene did not correlate with expression levels (neither mRNA nor protein). Further investigations are needed for better understanding the exact role of these MMPs in the pathogenesis of ICH in CFXIIID and also identifying the regulatory mechanisms.

P310

GENETIC CONFIRMATION AND FINDING NOVEL MUTATIONS IN GLANZMANN THROMBASTHENIA AND VON WILLEBRAND DISEASE FAMILIES BY DIAGNOSTIC EXOME SEQUENCING

Y.J. Shim[1,*], E.M. Choi[1], H.S. Kim[1], J.M. Lee[2]
[1]Pediatrics, Keimyung University School of Medicine and Dongsan Medical Center, [2]Pediatrics, Yeungnam University, College of Medicine, Daegu, Korea, Republic Of

Background: Congenital platelet function disorders and von Willebrad disease (vWD) are very heterogeneous group resulting in primary hemostatic defects. Physicians generally have difficulty to confirm them due to complicated diagnostic technique.
Aims: We intended to apply diagnostic exome sequencing (DES) for genetic confirmation and finding causative variants in children with primary hemostatic problems.
Methods: Library preparation was performed with TruSight One sequencing panel (Illumina, USA), which enriches about 4,800 genes with clinical relevance. Massively parallel sequencing was conducted with NextSeq (Illumina). Variants were annotated with population databases (1000 Genomes Project, Exome Variant Server, Exome Aggregation Consortium) and disease databases (OMIM). For missense variant, in-silico analysis was done with SIFT, PolyPhen-2, and MutationTaster. Candidate variants were confirmed by Sanger sequencing and family study. For *VWF* gene, multiplex ligation dependent probe amplification assay was also done using SALSA MLPA probemix P011-B3/P012-B3. Among variants from genes of primary interest, common variant with minor allele frequency ≥1% using population databases were filtered out. In addition, variants detected in more than 2% in in-house database were further filtered out to remove population specific polymorphism or platform specific errors. For VWF exons of either incomplete coverage or low mapping quality due to highly homologous region (exon 26, 24), additional Sanger sequencing was performed. Genes of primary interest were those associated with platelet dysfunction; vWD (*VWF*), Bernard–Soulier syndrome (*GP1BA, GP1BB, GP9*), Glanzmann thrombasthenia (GT) (*ITGA2B, ITGB3*), Thromboxane A2 receptor defect (*TBXA2R*), ADP receptor defect (*P2RY12*), Gray platelet syndrome (*NBEAL2*), Quebec platelet disorder (*PLAU*), ARC syndrome (*VPS33B*), Hermansky-Pudlak syndrome (*HPS1, AP3B1, HPS3, HPS4, HPS5, HPS6, DTNBP1, BLOC1S3*), Chediak-Higashi syndrome (*LYST*), Griscelli syndrome (*MYO5A, RAB27A, MLPH*), Scott syndrome (*ABCA1*).
Results: Twelve children with easy bruising, frequent epistaxis, or menorrhagia and their family members were enrolled. Two unrelated children were confirmed as GT. One proband had compound heterozygous variants of c.1913+5G>T and c.1451G>T (p. Gly484Val) in *ITGB3*. The former was pathogenic which results in aberrant splicing and the latter is novel. The other proband had homozygous variant of c.1913+5G>T in *ITGB3*. Three unrelated children were confirmed as vWD. One proband had compound heterozygous variants of c.2574C>G (p.Cys858Trp) and c.3390C>T (p.Pro1127_Gly1180delinsArg) in *VWF*, especially the latter synonymous variant previously confirmed to be resulted in exon 26 skipping. Another proband had a novel variant, c.2008C>T (p.Arg670Cys). The last proband had a known *VWF* pathogenic variant of c.1728G>T (p.Met576Ile).
Summary/Conclusions: DES is a valuable method to confirm GT or vWD. Further study is needed to find out unidentifiable mutations by this strategy.

P311

HPA-3A/3A GENOTYPE IS A POSSIBLE RISK FACTOR OF SEVERE HEMORRHAGIC SYNDROME IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA

Z. Irina[1,*], K. Sergey[1], G. Sergey[1], M. Natalya[1], G. Svetlana[1], B. Stanislav[1], C. Aleksandr[1]
[1]hematology, Russian Research Institute of hematology, Saint-Petersburg, Russian Federation

Background: The main clinical manifestation of primary immune thrombocytopenia (ITP) is hemorrhagic syndrome (HS) of different severity-from a lack or minimal cutaneous hemorrhages to severe life-threatening bleeding. It is well known, that there is no stable correlation between the platelets count or other parameter(s) and the hemorrhage grade in ITP patients. Possibly, the genetically-based individual mechanisms of immune response impairment could affect the clinical course of ITP, in particular, the severity of HS.
Aims: To reveal genetic risk factor(s) for severe HS in patients with chronic ITP.
Methods: A total of 67 patients (58 women and 9 men) with chronic ITP were involved in the study. The median age of the group was 57 years (range: 24-77). The mean duration of ITP was 7 years (2-48). Hemorrhage was graded according to WHO scale. Taking into account the severity of HS, all the patients were divided into two groups. The first group included 40 patients with HS of 0-1 grade and the second consisted of 27 patients with HS of 2-3 grade. All patients of the second group needed the use of different methods of emergency haemostatic therapy and we consider it as a "severe ITP". We analyzed DNA polymorphism of 8 genes responsible for the formation of specific human platelet alloantigen systems (HPA-1, -2, -3 and -5) or associated with impaired immune response (IL-1B, IL-6, IL-10 and TNF-A). The differences in genotype frequencies between the groups 1 and 2 were assessed by Fisher's exact method. Odds ratios (OR), their 95% confidence intervals (CI) and p-values were calculated with GraphPad Prism 5.0 software.
Results: The frequency of HPA-3a/3a (GpIIb 2622TT, 843 Ile/Ile) genotype was more than 2-fold increased in ITP patients with severe HS (55.6% *vs* 25.0% in the group with HS of 0-1 grade; OR=3.8, 95% CI: 1.3-10.7, p=0.02). HPA-1a/1a and HPA-2a/2a genotypes were also more frequently seen in patients with HS of grade 2-3 when compared to the group HS 0-1 (77.8% *vs* 72.5% and 92.6% *vs* 80.0%, respectively), but these differences were not statistically different (p=0.78 and p=0.19, respectively). Moreover, in the group with "severe ITP" we found almost 2-fold increase of the IL-6 -174CC genotype frequency (26.9% vs.15.0% in HS 0-1; OR=2.1, 95% CI: 0.6-7.1, p=0.34). Patients positive for IL-10 -592A allele were also more frequently seen in the group with HS of 2-3 grade (48.1% vs.26.3% in HS 0-1; OR=2.6, 95% CI: 0.9-7.4, p=0.11).
Summary/Conclusions: Our data indicate that HPA-3a/3a variant could be a possible risk factor for severe HS in ITP patients.

P312

AN ALGORITHM TO IDENTITY CASES OF SEVERE HEMORRHAGE IN ROUTINELY COLLECTED HEALTHCARE DATA

A. Kreuger[1,2,*], R. middelburg[1], J.L. Kerkhoffs[3], J. van der Bom[1]
[1]Center for Clinical Transfusion Research, Sanquin Research, [2]clinical epidemiology, LUMC, Leiden, [3]Hematology, Hagaziekenhuis, den haag, Netherlands

Background: Many patients with a hematological malignancy have an increased risk of hemorrhages. Research addressing the causes of these hemorrhages, especially those on major hemorrhages, are hampered by the difficulty to find sufficient and representative cases of major hemorrhage. Unfortunately, electronic health records generally do not codify hemorrhages.
Aims: The aim of this study was to develop an algorithm that can be used to find patients who suffered from major hemorrhages (WHO grade 3 or 4) within electronic health records.
Methods: An algorithm was developed using electronic health record data of a cohort of patients with acute leukemia, who received platelet transfusions between June 2011 and December 2015 at the Leiden University Medical Center in the Netherlands. Chart review was performed for a stratified, random sample of observation days. Discriminative performance of three indicators was assessed: CT-brain, drop in hemoglobin level and transfusion need within 24 hours. The cut off values for hemoglobin drop and transfusion need with the best discriminating capacity and CT-brain were entered in the final algorithm. The C-statistic was calculated and calibration plots were made. The algorithm will be externally validated in two other academic hospitals.
Results: The derivation cohort consisted of 255 patients comprising 10,638 observation days and chart review was performed for 353 days. The incidence of major hemorrhage was 0.22 per 100 observation days. The final algorithm consisted of information on CT-brain (yes/no), a hemoglobin drop of ≥2.8 g/dl and the need of six or more transfusions (yes/no). The C-statistic of the algorithm was 0.93 (95% confidence interval (CI) 0.86 to 0.99). The incidence of bleedings with all grades of severity was 8.4 per 100 days. The algorithm for bleedings of all grades had a c-statistic of 0.54 (CI 0.53 to 0.55). The results of the external validation are not available yet.
Summary/Conclusions: An algorithm using information on CT-brain, hemoglobin drop and transfusion can accurately identify cases of major hemorrhage within electronic health care data. External validation will be performed.

Myelodysplastic syndromes – Clinical 1

P313

MOLECULAR MECHANISMS AND CLINICAL SIGNIFICANCE OF REDUCED PTPN1 EXPRESSION IN MYELODYSPLASTIC SYNDROMES

M. Shiseki[1,*], M. Isii[1], M. Ohwashi[1], N. Mori[1], K. Yoshinaga [1], J. Tanaka[1]
[1]Department of Hematology, Tokyo Women's Medical University, Tokyo, Japan

Background: Previously we determined common deleted region (CDR) of del(20q) observed in MDS by CGH-array. Our data showed that the *PTPN1* gene is located within CDR of del(20q). The *PTPN1* gene encodes PTP-1B, a non-receptor type protein tyrosine phosphatase, which is involved in multiple physiological and pathological cellular processes via dephosphorylation of several tyrosine kinases, and other molecules. Although roles of PTP-1B in normal and pathological hematopoiesis has not been elucidated, it may function negative regulator for cellular processes mediated by tyrosine kinases, including JAK2, and SRC. We hypothesized that the *PTPN1* gene is a target gene disrupt by del(20q), resulting in haplo-insufficiency, and involved in MDS molecular pathogenesis.
Aims: We attempted to examine PTPN1 expression level in bone marrow cells of MDS patients with or without del(20q), and to investigate its clinical and biological significance.
Methods: Total RNA was extracted for cDNA synthesis from bone marrow samples taken at the time of diagnosis with written informed consent from patients and control subjects were used for the present study. Real-time RT-PCR was carried out to quantify PTPN1 expression by the TaqMan probe method using an ABI 7500 real-time PCR system (Applied Biosystems). Data including patients' demographic, disease status, medical history, clinical and laboratory findings, and outcome, were collected from medical records and laboratory data base. A non-parametric Mann-Whiteny-Wilcoxon test was used to examine whether expression levels among groups are statistically different. The Kaplan-Meier model was used to analyze the impact of PTPN1 expression on overall survival, and log-rank test was used for statistical analysis. We also examined the effect of 5-azacytidine treatment on PTPN1 expression in primary bone marrow cells from MDS patients. Bone marrow cells were cultured with or without 5mM of 5-azacytidine for 48 hours. Expression level of PTPN1 was examined by quantitative RT-PCR described as above.
Results: A total of 118 MDS patients, 71 males and 47 females with median age of 68 years (range: 20-91 years) and 19 control subjects were included in the present study. The patients were classified as RCUD (n=18), RCMD (n=58), RARS (n=8), RAEB-1 (n=20), and RAEB-2 (n=14) according to WHO classification. Relative PTPN1 expression level was significantly decreased in MDS patients with del(20q) (P<0.001) compared with control subjects. Moreover, relative PTPN1 expression level in MDS patients without del(20q) also significantly decreased (P<0.001). Expression patterns of PTPN1 among five WHO-subtypes, were statistical different (*P*=0.0201). Median values of relative PTPN1 expression level in RCUD, RCMD, RARS, RAEB-1, and RAEB-2 were 1.52, 1.95, 1.94, 1.46, and 1,26 respectively. Relative PTPN1 expression level in WHO-subtypes with high blast counts (RAEB-1 and RAEB-2) was significantly lower than that in WHO-subtypes with less blast counts (RCUD, RCMD, RARS) (median value: 1.41 *vs* 1.89, *P*=0.0074). To investigate prognostic implication of PTPN1 expression in MDS, we analyzed impact of PTPN1 expression on overall survival (OS). Based on PTPN1 expression level, 118 patients were divided into four groups, high (Q1), intermediate (Q2, Q3), and low (Q4) quartiles. Kaplan-Meier analysis demonstrated that the lowest quartile (Q4) showed significantly worse survival compared with remaining quartiles (Q1, Q2, Q3) (*P*=0.048). The estimated 5-year OS rates in Q1-3 group and Q4 group were 69% and 49.8%, respectively. We examined whether PTPN1 expression is induced by 5-azacytidine in primary bone marrow cells of 17 MDS patients. Real-time PCR analyses indicated that 5-azacytidine treatment significantly induced PTPN1 expression.
Summary/Conclusions: The present study demonstrated that PTPN1 expression is reduced in MDS patients by haplo-insufficiency due to del(20q) and methylation of promotor region of the *PTPN1* gene. Low PTPN1 expression is associated with advanced disease and poorer clinical outcome, indicating that PTPN1 expression level could be a useful prognostic marker in MDS. .

P314

MOLECULAR MARKERS PREDICTING RESPONSE TO AZACITIDINE TREATMENT FOR MYELODYSPLASTIC SYNDROMES

Background: DNA hypomethylating agents (HMAs) comprise standard therapy for non-transplant-candidate high-risk myelodysplastic syndromes (MDS). However, little is known about the exact mechanism of their effects to MDS or no reliable makers predicting the response to HMAs have been developed, although a recent study reported a very high response rate of *TP53*-mutated AML and MDS to decitabine.
Aims: The purpose of this study is to elucidate the clonal dynamics and molecular signatures that correlate with response to azacitidine therapy for MDS, focusing on the role of *TP53*-mutations.
Methods: We conducted a prospective multicenter trial of azacitidine treatment for high-risk MDS patients, in which the efficacy was compared between the 5-day and 7-day regimens. A total of 107 patients were enrolled between 2013 and 2016. For all cases, a bone marrow specimens collected before treatment was analyzed for mutations using targeted-capture sequencing. Mutations were also interrogated after 4 cycles of azacitidine therapy in 48 (45%) cases. An additional 24 cases was also analyzed for mutations who received azacitidine therapy for MDS and whose bone marrow specimens were available both before and after therapy. RNA baits were designed for detection of both oncogenic variants in 67 known driver genes in myeloid neoplasms and copy number alterations on the same platform. Response was evaluated according to the IWG 2006 criteria. We also evaluated the difference in the size of clones showing the maximum allelic burden between pre- and post-treatment specimens (ΔTCF: tumor cell fraction).
Results: On average, 2.7 mutations (range 0-9) were detected per sample before azacitidine treatment. *TP53* represented the most common mutational target affecting 29 (27%) and 10 (42%) cases in the on- and off-protocol cohort, respectively, followed by *ASXL1, RUNX1, TET2*, and *SRSF2*. *TP53*-mutated cases had significantly lower number of driver mutations (1.7 *vs* 3.1/sample, p<0.001) and higher number of copy number changes (9.6 *vs* 2.1, p<0.001), compared with unmutated cases. Clinical response was observed in 25 cases in the on-protocol cohort, including 6 complete remission (CR) (5.6%) and 19 marrow CR (mCR) (17.8%) and 7 (29%) cases (all CR) in the off-protocol cohort. Notably, CR was obtained almost exclusively in *TP53*-mutated cases (5/6 and 5/7 CR cases in the on- and off-protocol cohort. No other mutations were significantly associated with clinical response. Median time to CR was 119 days (range: 81–721), which lasted for a median duration of 217 days (range 10 –783). ΔTCF was evaluable for 62 cases who had one or more follow-up specimens and carried at least one mutation in either pre- or post-treatment with an average of –0.075 (range: –0.75–0.72). ΔTCF was significantly lower in responders than non-responders (–0.18 *vs* –0.0002, p=0.0068) and in *TP53*-mutated than unmutated cases (–0.25 *vs* 0.0058, p=0.001).
Summary/Conclusions: Our study revealed a significant positive association of *TP53* mutations with favorable responses to azacitidine for MDS, although the response was transient and the expected response rate seems to be much lower compared to that reported for decitabine. Given that decitabine is not approved for MDS in many areas (*e.g.* EU and Japan), our results suggests a potential role of azacitidine as a key agent to improve the notoriously dismal clinical outcomes of *TP53*-mutated tumors. Further study should be warranted to confirm its efficacy and to develop an optimal post-remission therapy to overcome the short remission period.

P315

UPDATED RESULTS FROM PHASE 2 STUDY OF GUADECITABINE FOR PATIENTS WITH UNTREATED INT-2/HIGH RISK MYELODYSPLASTIC SYNDROMES OR CHRONIC MYELOMONOCYTIC LEUKEMIA

[1]Leukemia, [2]MD Anderson Cancer Center, Houston, United States, [3]Biostatistics, [4]Hematopathology, MD Anderson Cancer Center, Houston, United States

Background: Improving the current response and survival outcomes of patients with higher risk MDS and CMML is fundamental. Guadecitabine is a next generation hypomethylating agent with increased length of exposure compared to decitabine and clinical activity in patients with MDS.
Aims: To evaluate the activity of guadecitabine in previously untreated patients with higher-risk MDS or CMML.
Methods: We conducted a single arm phase II clinical trial of guadecitabine at a dose of 60mg/m^2 sc daily for 5 days (days 1-5) every 28 days for patients with newly diagnosed MDS or CMML classified as Intermediate-2 or High risk by IPSS. Primary endpoint was complete response (CR). Responses were evaluated following the revised 2006 International Working Group criteria. Sequencing data was obtained at the time of pre-treatment evaluation by the use of a 28-gene next generation sequencing platform. Study included stopping rules for response and toxicity. Overall survival (OS) was censored at the time of transplant.
Results: A total of 53 patients have been enrolled: 50 (94%) are evaluable for toxicity and 44 (83%) for response. Median age is 67 years (49-87). A total of 43 (86%) patients have MDS and 7 (14%) have CMML. A total of 21 (42%) have complex karyotype. Sequencing data was available in 48 (96%) patients with *TP53* mutations being the most frequently detected in 36% patients. After a median of 6 treatment cycles (1-20), the ORR is 71% including 32% CR. Median best response occurred by 3 cycles (1-6). Seven (21%) out of 33 evaluable patients achieved a complete cytogenetic response. Ten (20%) subjects proceed to allogeneic stem cell transplantation. Median follow up was 6.3 months (0-23). Median OS is 14.1 months (CI 13.3-14.9 months) and median EFS is 8.4 months (CI 5.6-11.2 months). Forty-five (90%) patients experienced at least one AE during therapy. Most common grade 1-2 AEs included fatigue (66%), nausea (38%) and dyspnea (26%). Dose reductions due to cytopenias were required in 17 (34%) patients. Early 8-week mortality occurred in 3 (6%) patients.
Summary/Conclusions: Guadecitabine is well-tolerated and active in patients with higher-risk MDS and CMML even in the presence of adverse biological features such as high frequency of complex karyotype, therapy related disease and *TP53* mutations.

P316

AZACITIDINE IMPROVES OUTCOME IN HIGH RISK MDS PATIENTS WITH CHROMOSOME 7 ABNORMALITIES: RETROSPECTIVE COMPARISON OF GESMD AND GFM REGISTRIES

Background: A benefit of treatment with azacitidine (AZA) in higher-risk (intermediate-2 and high risk by IPSS) Myelodysplastic syndromes (HR-MDS) patients with abnormalities of chromosome 7 (Abn 7) has been suggested in relatively small studies.
Aims: Our purpose was to confirm this benefit in a larger patient series.
Methods: Retrospective study of 235 HR-MDS patients with Abn 7 treated with AZA (n=115) *vs* best supportive care (BSC; n=120), assessing AZA treatment as time-varying variable in multivariable analysis.
Results: Seventy-four (64%) of AZA patients had de novo MDS and 41 (36%) had therapy related (secondary MDS), compared to 70 (90%) and 8 patients (10%) in the BSC group (*P*=0.0001). According to WHO 2008 classification, 65% in the AZA group and 48% in the BSC groups had refractory anemia with excess of blasts type 2 (RAEB-2) or secondary acute myeloid leukemia (AML with <30% of blasts) (p=0.015). The AZA and BSC groups were well balanced in terms of age, gender, cytogenetic risk category, and IPSS risk. In the AZA group, 55% patients were IPSS high-risk and 45% intermediate-2-risk and 61% had Complex-K, 23% non-complex -7, 14% non-complex del(7q), and only 2 patients (1.8%) had non-complex 7p-. Nevertheless, regarding MDS classification and MDS subtype (de novo *vs* secondary) was unbalanced with more patients with RAEB-2+AML (65% *vs* 48%, p<0.015) and secondary MDS (36% *vs* 10% <0.001), in the AZA group as compared to BSC patients. Median follow-up time from diagnosis was 47.5 months (95% CI: 24.2 – 122.9) in the AZA group and 59.8 months (95% CI: 15.5 - not reached) in the BSC group (*P*=ns). Median time from diagnosis to AZA treatment was 2 months (range 0 – 66.2). Ninety-two patients (80%) received AZA according to the conventional 7 days every 28 days schedule whereas 20% received 5-day cycles. The median number of AZA cycles received was 5 (range, 1-32). Response to AZA: Twelve patients were not evaluable for response according to IWG 2006 criteria because no complete data was recovered. In the 103 patients evaluable for response in the AZA group, the overall RR (ORR) was 37.9% (39/103), including 14.6% CR and 23.3% SD with HI. Among AZA non-responders (62.1%), 27.1% had SD without HI, 23.3% PD, and 11.7% (n=12) had early death (8, infection; 1, bleeding, 3, unknown cause). According to cytogenetic, the ORR was 38.1% in patients with CK, 32% in patients with non complex -7 and 46.2% in patients

with non complex del(7q) (*P*=ns for complex *vs* non complex, chi-square test). The ORR was 37.5% in "*de novo*" and 38.4% in secondary MDS, respectively (*P*=ns). Impact of AZA treatment compared to BSC on overall survival: Results of this multivariable analysis of OS at different time points are presented in Table 2. Chromosome 7 cytogenetic categories and IPSS retained a poor prognosis over time with a constant value of poor prognosis. AZA treatment had a favorable impact on OS during the first 3 years of treatment, compared to BSC, confirming results obtained in univariable analysis. Nevertheless, the benefit of AZA treatment as compared to BSC approach decreased as time spends and the HR value increased over time: HR of 0.3 at 6 months, 0.5 at 1 year and 0.7 at 2 and 3 years after treatment. (Figure 1). This benefit was present in all chromosome 7 categories with a a trend towards better impact among patients with complex karyotype but no significant differences between the 3 categories (-7, del(7q) and CK).

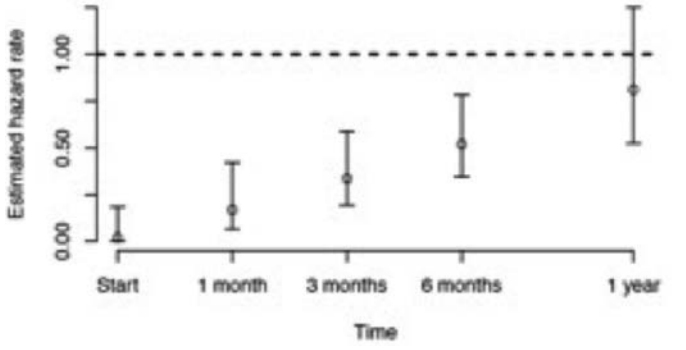

Figure 1.

Summary/Conclusions: This study confirms the benefit of AZA treatment on outcome in patients with HR-MDS and cytogenetic abnormalities involving chromosome 7.

P317

UN UPDATE OF A PHASE II EXPLORATORY STUDY OF OPN-305, A TOLL-LIKE RECEPTOR 2 ANTIBODY, IN PATIENTS WITH LOWER RISK MYELODYSPLASTIC SYNDROMES WITH PRIOR HYPOMETHYLATING AGENT THERAPY

G. Garcia-Manero[1,*], G. Montalban-Bravo[1], H. Yang[1], Y. Wei[1], Y. Alvarado[1], C. DiNardo[1], N. Daver[1], M. Konopleva[1], K. Hearn[1], R. Miller[2], S. Arbe-Barnes[2], P. McGuirk[2], T. Kearney[2], B. Keogh[2], H. Kantarjian[1], M. Reilly[2]
[1]Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States, [2]Opsona Therapeutics, Dublin, Ireland

Background: Alterations of innate immune signaling, including overexpression of TLR2, are common in MDS. Significant TLR2 overexpression in MDS bone marrow CD34+ cells, especially after HMA therapy, has been reported. OPN-305 is a fully humanized antagonistic IgG4 kappa monoclonal antibody to TLR2 which significantly increases the formation of erythroid colonies (CFU-E) in BM CD34+ cells isolated from pts with lower-risk MDS *in vitro*.
Aims: To evaluate the potential therapeutic value of OPN-305 in patients (pts) with MDS
Methods: We designed a phase I/II trial of OPN-305 for pts with Low or Int-1 risk MDS by IPSS after failure to prior therapy with a HMA (≥4 cycles). Pts where required to be transfusion dependent (≥2 units in 8 weeks). Pts with isolated del(5q) should have received therapy with lenalidomide. Because, OPN-305 had not been previously used in pts with hematological malignancies, the study had an initial phase of N=10 pts using OPN-305 at a dose of 5 mg/kg every 4 weeks for a maximum of 9 cycles. Therapy could be repeated as long as there was no excess toxicity or progression. If after 16 weeks of therapy, there was no response, azacitidine on a 3 day schedule, could be added to OPN-305. Responses were evaluated following the revised 2006 IWG criteria. This initial cohort allowed evaluation of toxicity, pharmacokinetic analysis, receptor occupancy, and sequential analysis of cytokine profile. An extension dose escalation phase to 10mg/kg was planned for N=30 pts.
Results: At the time of this report, 31 pts have been enrolled, 11 at the initial 5 mg dose and 21 at 10 mg/kg. A total of 21 pts are evaluable for toxicity and response. Median age was 72 years (range 42-87). Nine (43%) pts were classified as Low risk and 12 (57%) as Intermediate-1 risk by IPSS. Thirteen pts had normal karyotype, 2 del(5q), 2 trisomy 8, 1 del(20q), 1 monosomy Y and 2 other single or double abnormalities. Median number of prior therapies was 2 (range 1-4) with a median duration of prior therapies of 23 months (range 6-56). A total of 5 (29%) pts developed AEs related to OPN-305. All AEs were grade 1 with gastrointestinal disorders being the most frequent (23%). At this point, no significant drug related toxicity has been documented with no excess infectious complications. Overall response rate in the form of hematological improvement was 53% (8/21) with 3 (20%) pts achieving transfusion independence and 5 (33%) minor hematological improvement. Half-lives of OPN-305 in serum were >200 h at 5 mg/kg and >300 h at 10 mg/kg. There was a greater-than-dose proportional increase in mean OPN-305 exposure (AUC) between 5 and 10 mg/kg. PK profiles after repeated dosing at 5 mg/kg in N=2 subjects and pre-dose (trough) levels in other subjects indicated some variability in the potential for accumulation. TLR-2 receptor occupancy in blood PBMCs and bone marrow aspirates was complete in virtually all samples taken after OPN-305 administration. There is no evidence of treatment related anti-drug antibodies. Compared with baseline, no significant changes of IL-23, IL-18, IFN-r, IL-10, IL-1β, IL-6, IL-12 (p40), IL-12 (p70) and IL-8 levels where observed among responders or non-responders or based on OPN-305 dosing. A trend to increased response was observed in patients with higher TLR2 expression, with no differences in response based on cytogenetic or mutational profile.
Summary/Conclusions: Treatment with OPN-305 in pts with previously treated lower-risk MDS was well tolerated with no significant toxicities and 53% ORR including 20% transfusion independence, and potential association between TLR2 levels and response.

P318

IN PATIENTS UNDEGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR MDS DEVELOPMENT OF CHRONIC GVHD COULD AMELIORATE THE ADVERSE IMPACT OF SPECIFIC SOMATIC MUTATIONS

J.C. Caballero Berrocal[1,*], M. Sánchez Barba[2], J.M. Hernández Sánchez[3], M. Del Rey[3], K. Janusz[3], C. Chillón[4], E. Such[5], C. José[5], G. Sanz[5], A.M. Hurtado[6], C. Díez Campelo[19]
[1]Hematology Department, University Hospital of Salamanca, [2]Department of Statistics, [3]Centro de Investigación del Cáncer, IBMCC Instituto de Biología molecular y celular del cáncer, University of Salamanca, [4]Molecular Biology Department, University Hospital of Salamanca, Salamanca, [5]Hematology Department, University Hospital La Fe, Valencia, [6]Hematology and Medical Oncology Department, University Hospital Morales Meseguer, Murcia, [7]Hematology Department, University Hospital Virgen del Rocío, Sevilla, [8]Hematology Department, University Hospital Vall d'Hebron, Barcelona, [9]Area of Genetic and Cellular Therapy, IBSAL Instituto Biosanitario de Salamanca, Salamanca, Spain

Background: Approximately 90% of patients with Myelodysplastic Syndromes (MDS) have somatic mutations in driver genes detected by Next Generation Sequencing (NGS). In the last years, several studies have related these mutations with prognosis, disease characteristics and response to therapy, including allogeneic Hematopoietic Stem Cell Transplantation (HSCT). Development of Chronic Graft Versus Host Disease (cGVHD) has been reported as one of the most powerful antineoplastic mechanisms after HSCT.
Aims: To evaluate the impact of specific somatic mutations in patients with MDS undergoing HSCT and if the development of cGVHD can modify their prognosis.
Methods: The results of HSCT in 115 MDS patients from five centres in Spain were retrospectively analyzed. Bone marrow samples were collected a median of 27 days prior to transplant and DNA was screened for somatic mutations by NGS, using a NextSeq platform (Illumina). Two myeloid genes panels that included the most frequently mutated genes in myeloid malignancies were used.
Results: Median age was 53 years (range from 19 to 70). Fifty-eight percent were male and 79.13% were classified as *de novo* MDS. According to WHO 2008 classification 4 (3.5%) were RCUD, 2 (1.8%) RARS, 22 (19.50%) RCMD, 28 (24.8%) RAEB-1, 32 (28.3%) RAEB-2, 12 (10.6%) Unclassifiable MDS, 9 (8%) CMML and 4 (3.5%) were AML (FAB RAEB-T). Among patients with calculated Revised IPSS (R-IPSS) (85 of 115 patients) 2 (2.4%) had very low risk, 15 (17.6%) low risk, 21 (24.7%) intermediate risk, 22 (25.9%) high risk and 16 (18.8%) had very high risk; 9 patients with CMML (10.6%) were categorized separately. Among patients with known karyotype (101 of 115), 7 of them (6.9%) had a complex kariotype (CK). Regarding mutational study, 44 patients (38.3%) didn't shown any mutation before transplant; 27 patients (23.5%) had 1 mutated gene, 15 (13%) had 2, 19 (16.5%) had 3, 6 (5.2%) had 4, 3 (32.6%) had 5 and only 1 patient (0.9%) had 6 different mutated genes. The most frequently mutated genes were: *TP53* in 15 patients (13%), *SRSF2* in 14 (12.2%), *TET2* in 13 (11.3%), *DNMT3A* in 9 (7.8%), *RUNX1* in 9 (7.8%), *SF3B1* in 9 (7.8%) and *ASXL1* in 8 (7%) patients. After a median of follow up for survivors of 2.02 years, Overall Survival (OS) was 48.1% (63.4% at 1 year; median 5.96). Patients were divided into 2 groups: group 1, with 2 or less mutated genes (74.5%) and group 2, with more than 2 mutated genes (25.2%). Group 2 had a lower OS (46.9% *vs* 69.6% at 1 year; p=0.035) and a higher Cumulative Incidence of Relapse (CIR) (25.3% *vs* 10.1% at 1 year; p=0.007). Development of cGVHD significantly improved outcome in both groups (Figure 1). Univariate analysis determined that developing of cGVHD, CK, number of mutated genes (more than 2 mutated genes) and mutations in *TET2* significantly impacted on outcome. Nevertheless, only the development of cGVHD as a time-dependent variable (HR 0.046, 95%CI 0.016-0.138, p<0.001) and *TET2* mutations (HR 2.562, 95%CI 1.018-6.447, p=0.046) significantly influenced on OS in multi-

variate analysis. We also observed the unfavourable impact of *TP53* mutations on relapse risk: CIR was 41.7% (95% CI 22.5-77.1) at 1 year for *TP53* mutated *vs* 9.8% (95% CI 5.3-18.1) at 1 year for non *TP53* mutated patients (p=0.006).

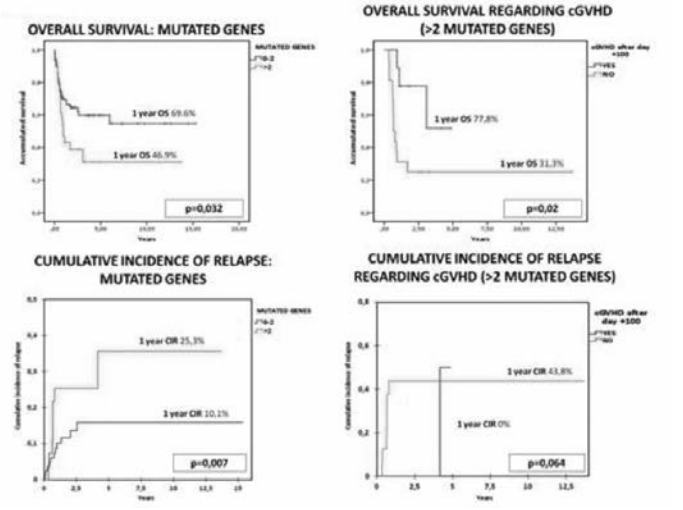

Figure 1.

Summary/Conclusions: We conclude that the number of mutated genes prior to transplant could be a prognostic factor of OS and CIR. Mutations in some genes, like *TET2* and *TP53,* could also have an adverse impact on outcome. However, cGVHD could ameliorate the poor prognosis of somatic mutations in transplanted patients with MDS.

P319

VOSAROXIN PLUS AZACITIDINE TREATMENT FOR PATIENTS WITH MYELODYSPLASTIC SYNDROME: A PHASE 1/COHORT EXPANSION STUDY

M.A. Jacoby[1,*], M.J. Walter[1], J.F. DiPersio[1], C.N. Abboud[1], P. Westervelt[1], A.F. Cashen[1], K. Stockerl-Goldstein[1], T. Fletcher[1], G.L. Uy[1]
[1]Medicine, Washington University Medical School, St. Louis, United States

Background: Although hypomethylating agents are the mainstay of treatment for myelodysplastic syndromes (MDS), these agents result in remissions in a minority of patients and are not curative. Vosaroxin is a first-in-class quinolone derivative that intercalates DNA and inhibits topoisomerase II. Vosaroxin is active with a tolerable safety profile in acute myeloid leukemia (AML) and the novel combination of vosaroxin and azacitidine was found to be synergistic in primary myeloblasts.
Aims: This phase 1/cohort expansion study was designed to determine the maximum tolerated dose (MTD) and dose-limiting toxicity (DLT) of vosaroxin when given in combination with azacitidine, and to evaluate the efficacy and safety of the combination treatment.
Methods: Patients with MDS ≥18 years old with cytopenias requiring transfusions, an IPSS score of intermediate (INT)-1 or greater, or chronic myelomonocytic leukemia were eligible. Vosaroxin (initial dose: 50 mg/m^2/d) was administered on Days 1 and 4, and azacitidine (75 mg/m^2/d) on Days 1-7 of a 28-day cycle, in an outpatient setting, for up to 6 cycles in a 3+3 design (additional cycles were permitted if a clear benefit for the patient was demonstrated). Once the MTD was determined, an expansion cohort of 20 evaluable patients (≥1 cycle) was enrolled.
Results: A total of 35 patients enrolled in the dose escalation (n=13) and expansion (n=22) phases. The median age of the entire cohort was 66 years (range 38-77) with IPSS scores of low (n=1); INT-1 (n=13); INT-2 (n=15); and high risk (n=6). The median ECOG score for the entire cohort was 1 (range 0-2). In the dose escalation phase, at the initial dose of vosaroxin 50 mg/m^2/d (n=6), the median number of total cycles was 2 (range: 1-4); 2 of 6 patients experienced a DLT at this dose (grade 4 hyperbilirubinemia and grade 4 neutropenia >42 days). At the de-escalated dose of 34 mg/m^2/d (n=7), the median number of cycles was 2 (range: 1-18); 1 patient experienced a DLT at this dose (grade 4 mucositis). The MTD of vosaroxin was determined to be 34 mg/m^2/d and this dose was used in the expansion phase. Incidences of ≥grade 3 non-hematologic adverse events considered possibly, probably, or definitely drug-related for the total cohort (n=35) included infections (n=38), non-neutropenic fever (n=1); neutropenic fever (n=23); bleeding (n=9); and GI (mucositis/colitis/dysphagia; n=4). Two deaths were considered possibly treatment-related (sepsis and diffuse alveolar hemorrhage). No cardiac toxicity attributable to study treatment was observed, even with prolonged therapy. Of the 35 enrolled patients, 32 have completed ≥1 cycle and are evaluable for response. Among these patients, median number of cycles completed is 3 (range, 1-18), with 5 still continuing with therapy. Best response rates are shown in the Table 1. The median number of cycles to best response was 1 (range: 1-6). Sixteen patients have received transplant to date.

Table 1.

Best Response, n (%)	Total Cohort Evaluable patients (N=32)	34 mg/m^2/d Cohorts Evaluable patients (n=27)
Overall Response Rates		
CR + PR + HI	18 (56)	15 (56)
CR + PR + mCR + HI	25 (78)	21 (78)
CR	**6 (19)**	**6 (22)**
PR	**1 (3)**	**1 (4)**
mCR/mCR-HI	**14 (44)**	**11 (41)**
mCR	7 (22)	6 (22)
mCR-HI-erythroid	1 (3)	1 (4)
mCR-HI-neutrophil	2 (6)	1 (4)
mCR-HI-platelets	3 (9)	2 (7)
mCR-HI-neutrophil/platelets	1 (3)	1 (4)
SD/SD-HI	**10 (31)**	**8 (30)**
SD	6 (19)	5 (19)
SD HI-neutrophil	1 (3)	0
SD HI platelets	2 (6)	2 (7)
SD HI-neutrophil/platelets	1 (3)	1 (4)
PD	**1 (3)**	**1 (4)**

CR, complete response; HI, hematologic improvement; mCR, marrow complete response; PD, progressive disease; PR, partial response; SD, stable disease

Summary/Conclusions: The MTD of vosaroxin in MDS patients was 34 mg/m^2/d when given on Days 1 and 4 with a fixed dose of 75 mg/m^2 of azacitidine on Days 1-7. The major non-hematologic toxicities were infections, febrile neutropenia, and bleeding. The combination of vosaroxin and azacitidine showed promising activity with responses rates comparable or better than those generally observed with azacitidine alone. Additionally, the transplant rate observed was encouraging in this patient population.

Myeloma and other monoclonal gammopathies - Biology

P320

ADVANCED STAGE MYELOMA IS CHARACTERIZED BY A SIGNIFICANT INCREASE OF MUTATIONS IN GENES ASSOCIATED WITH DRUG RESPONSE

Background: The amount of genomic data available in Multiple Myeloma (MM) is exponentially increasing, however, hardly any of that information is translated into the clinic. A number of genes has been associated with resistance to commonly used anti MM compounds. This, most importantly, includes immunomodulators (IMiDs) and proteasome inhibitors (PIs). However, no mutation screening has yet been amended to our MM routine diagnostic workflows. We investigated 458 MM patients by targeted sequencing, including the largest cohort of previously treated MM patients so far. We identified an increased mutation incidence in treated patients, yet unreported mutations and functionally validated a subset.
Aims: To describe the mutational spectrum in genes of pathways targeted by standard of care (SOC) therapies in a cohort of pretreated and previously untreated patients.
Methods: Tumor-germline paired samples of five contributing sites were pooled (Würzburg, Heidelberg, Madrid, Rotterdam and Mayo Clinic). Analysis included 310 untreated and 148 IMiD and/or PI treated patients. Targeted sequencing was performed using the M^{3}P (v2.0 or v3.0) gene selection, that includes most commonly mutated MM genes, actionable drug targets and genes being associated with drug resistance. Average sequencing depth increased 700X. Functional analyses of *PSMB5* mutations were conducted using Sleeping beauty vectors transposed into AMO1 cell line.

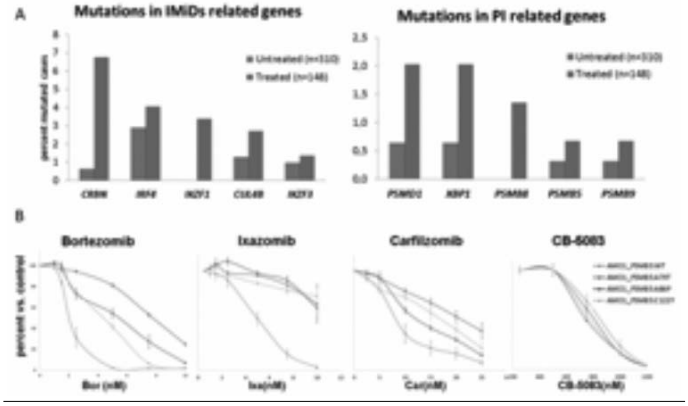

Figure 1. A: Mutation incidence in IMID related and PI related genes. B: Functional analysis of *PSMB5mut* expressing AMO-1 cells with different PI inhibitors and the P97 inhibitor CB-5083.

Results: Our analysis included five genes each with known association to drug response to IMiDs (*CRBN*, *CUL4B*, *IKZF1*, *IKZF3* and *IRF4*) and PIs (*PSMB5*, *PSMB8*, *PSMB9*, *PSMD1* and *XBP1*). Based on the increased sequencing depth, the mutation incidence in untreated patients is higher than in the CoMMPass dataset (IMiDs: 5.8% *vs* 3.9%; PIs: 1.9% *vs* 1.4%). Furthermore, pretreated patients showed a significant mutational increase compared with untreated pts (IMiDs: 19.7%, Z-score: -4.2, p<0.001; PIs: 7.3%, Z-score: -2.6, p=0.009). We observed a Gly159Arg mutation within the Lenalidomide (Len) degron sequence of *IKZF3* in a patient progressing on Len and Pomalidomide (Pom), as well as two XBP1 truncating mutations in PI refractory patients. Of note, among three treated cases with mutations in the β5 (*PSMB5*) or β5i (*PSMB8*) PI binding subunit of the proteasome, one patient harbored not less than 4 subclonal mutations. This is the first description of *PSMB5* mutations in human MM, identified in a patient with long term history of PI treatment. All mutations were located in or close to the Bor binding site of *PSMB5*. The functional analysis demonstrated induction of resistance not only to Bor ($IC_{50}^{PSMB5wt}$= 2 nM *vs* $IC_{50}^{PSMB5mut}$= 4.5-8 nM), but also to the second generation PI Ixazomib ($IC_{50}^{PSMB5wt}$= 5.2 nM *vs* $IC_{50}^{PSMB5mut}$= N/A) and Carfilzomib ($IC_{50}^{PSMB5wt}$= 8 nM *vs* $IC_{50}^{PSMB5mut}$= 13-22 nM). Of interest, the P97 blockade of the protein homeostasis by the investigational compound CB5083 remains still possible in the mutated cell lines and the resistance can be overcome. Finally, Pom treatment eradicated two of the *PSMB5* containing subclones (Figure 1).
Summary/Conclusions: Under the selective pressure of anti-MM therapy the incidence of mutations in genes associated with drug resistance increases over time. Resistance mechanisms evolve in parallel in competing (sub)clones of the disease, mimicking phenotype and behavior. Remarkably, despite our restrictive gene selection, a quarter of our treated cohort is affected by at least one mutation. Aim of future therapy may be the eradication of selected clones or subclones, which, according to our data, appears possible.

P321

ILF2-YB1 INTERACTION MODULATES RNA SPLICING TO INDUCE RESISTANCE TO DNA-DAMAGING AGENTS IN 1Q21-AMPLIFIED MULTIPLE MYELOMA

M. Marchesini[1,*], Y. Ogoti[1], E. Fiorini[1], M. D'Anca[2], P. Storti[3], L. Nezi[4], M. Kemal Samur[5], I. Ganan-Gomez[1], M.T. Fulciniti[5], L. Zhang[6], N. Giuliani[3], Z. Bohannan[1], K. Clise-Dwyer[7], N. Munshi[5], R. Orlowsky[8], G. Garcia-Manero[1], R.A. DePinho[9], S. Colla[1]

[1]Leukemia, MDAnderson Cancer Center, Houston, United States, [2]Neurology, University of Milan, Milan, [3]Clinical and Experimental Medicine, University of Parma, Parma, Italy, [4]Genomic Medicine, MDAnderson Cancer Center, Houston, [5]Harvard Medical School, Dana Farber Cancer Institute , Boston, [6]Informatic and Computational Biology, [7]Stem cell trasplantationa and cellular theraphy, [8]Lymphoma/Myeloma, [9]Cancer Biology, MDAnderson Cancer Center, Houston, United States

Background: The 1q21 amplification, which occurs in approximately 40% of de novo and 70% of relapsed Multiple Myeloma (MM), is among the most frequent chromosomal aberrations in MM patients and is considered a very high-risk genetic feature that is especially correlated with disease progression and drug resistance. The 1q21 amplicon contains many genes, and while it is unlikely that all contribute to the pathobiology of high-risk MM, the critical genes that do drive this high-risk phenotype have not yet been fully clarified. Identifying such genes and their contributions to this phenotype would enable the development of new and effective targeted therapy strategies for high-risk MM and thus improve their survival outcomes.
Aims: In our study we wanted to investigate the biological and molecular mechanisms behind the 1q21 amplification's contribution to high-risk MM with the ultimate goal of obtaining a list of validated therapeutic targets to inform the design of novel translational clinical trials for this subgroup of patients.
Methods: We conducted a high-resolution analysis of recurrent copy number alterations and expression profiles in a collection of 254 MM samples included in MMRC database. To define the discrete minimal common 1q21 region that is recurrently amplified in MM, we used Genomic Identification of Significant Targets in Cancer, a systematic method that identifies regions of genome that are recurrently amplified or deleted across a set of samples. These genes were enlisted into an *in vitro* screening strategy that employed a single-shRNA-per-96-well approach and GFP-competitive cell growth assay to identify 1q21 genes whose loss of function resulted in the selective death and/or growth inhibition of MM cells carrying the 1q21 amplification but not MM cells without the 1q21 amplification.
Results: We identified MCL1, UBAP2L, INTS3, LASS2, KRTCAP2 and ILF2 as potential 1q21-specific vulnerability targets whose expression is driven by copy number. We functionally validated, both *in vitro* and *in vivo*, Interleukin-2-enhancer binding factor 2 (ILF2) as a key 1q21 amplification-specific gene. Our results show that ILF2 impacts homologous recombination (HR) and induces resistance to DNA damaging agents routinely used in the treatment of MM, which is consistent with the observation that ILF2 expression correlates with poor survival in MM patient treated with high-dose melphalan followed by tandem autologous transplantation. On the mechanistic level, ILF2 interacts with numerous RNA binding proteins directly involved in the regulation of DNA Damage Response (DDR) by modulating alternative splicing of specific pre-mRNAs. RNA sequencing experiment confirmed that ILF2 knockdown results in aberrant splicing of genes involved in the DDR pathways and, strikingly, ILF2 RIP-seq analysis showed that ILF2 directly binds to transcripts involved in the regulation of the HR pathway, including components of BRCA1 protein complex. Furthermore, we found that ILF2 mediates drug resistance in dose-dependent manner by modulating YB-1 nuclear localization and interaction with the splicing factor U2AF65 to promote mRNA processing and stabilization of DDR genes in response to DNA damage (Figure 1).
Summary/Conclusions: In conclusion, our study reveals an intimate relationship among 1q21 amplification, mRNA splicing and DNA repair in the control of DDR in MM. On the basis of our findings, we propose that 1q21-driven ILF2 overexpression deregulates HR by stabilizing the mRNA splicing of critical HR

effectors, which enables genomic instability, promotes adaptive mechanisms to genotoxic stress, and enhances cell survival, thereby promoting drug resistance and disease progression. Given that 1q21 amplification is one of the most frequent copy number alterations in cancer, synthetic lethality approaches based on targeting gain-of-function associated to ILF2 may have a broad spectrum of application to potentiate the sensitivity of cancer cells to chemotherapeutic agents.

Background: High throughput techniques, such as next generation sequencing, are becoming an appealing approach to characterize multiple myeloma (MM) genomic profiles and better define risk assessment. However, the clinical relevance of such approaches is still largely unknown. The Multiple Myeloma Research Foundation (MMRF) CoMMpass trial (NCT01454297) has collected data from 1154 newly-diagnosed MM patients enrolled worldwide. Comprehensive analysis of somatic mutations in MM cells at diagnosis could unravel prognostically relevant disease characteristics not detectable with traditional approaches.
Aims: We analyzed data from the interim analysis 8 cohort (August 2015) to create a prognostic model.
Methods: CD138+ purified MM specimens from bone marrow aspirates and peripheral blood cells were collected at diagnosis. Whole exome libraries from both tumor and constitutional DNA samples were created. Somatic single nucleotide variants (SNV) were identified, only nonsynonymous SNV were included in the analysis. We evaluated the impact on progression free survival (PFS) of recurrently mutated genes (with at least a nonsynonymous SNV with an allele frequency of more than 5% in more than 10 patients) in a multivariable Cox model adjusted for international staging system (ISS) and cytogenetic profile (high risk, standard risk and missing). A backward selection based on the Akaike Information Criterion (AIC) was used to identify the final Cox model used to create a scoring system.
Results: 517 patients with baseline somatic mutation data were included in the analysis. Median age at diagnosis was 64 years (range 27-93), all patients received novel agents as first line treatment, 236 (45.6%) received autologous stem cell transplantation (ASCT). The most recurrent mutated genes were KRAS (25%) and NRAS (19.5%). Consistently with other works, DNA allele frequency data revealed that, in the great majority of cases, only a subclonal portion of MM cell DNA harbors a selected somatic SNV (data not shown). Based on the impact on PFS of recurrently mutated genes, a scoring system was developed. Four groups were identified according to the mutational status of 9 genes selected in a nonbiased manner (Table 1): group I (score 0-2, 17%); group II (score 3, 51%), group III (score 4-5, 26%) and group IV (score >5; 6%). After a median follow-up of 371 days, the 18-month PFS was 93% for group I, 85% for group II, 73% for group III and 40% for group IV (Figure 1). The hazard ratio was 2.31 (p=0.118) for group II *versus* group I, 4.45 (p=0.006) for group III *versus* I and 17.38 (p<0.001) for group IV *vs* I. The prognostic trend of the score was confirmed in different patient subgroups including ASCT/no ASCT, standard/high risk cytogenetic profile, ISS I, II, or III. Of note, 23% of patients in group I had ISS III and 34% of patients in group IV had ISS I.

Table 1.

Mutational score obtained by adding score for each parameter (total points).

Gene	Mutated Yes/No	Score assigned
PRRC2C	Yes	3
USH2A	Yes	2
RBP3	Yes	2
PKHD1	Yes	2
HRNR	Yes	2
FAT4	No	2
KRAS	Yes	1
FAT3	Yes	1
NRAS	No	1

Additive total score	
Group I	0-2
Group II	3
Group III	4-5
Group IV	>5

PFS stratified according to mutational score subgroups. Group I (score 0-2, red), group II (score=3, pink), group III (score 4-5, blue), group IV (score >5, purple).

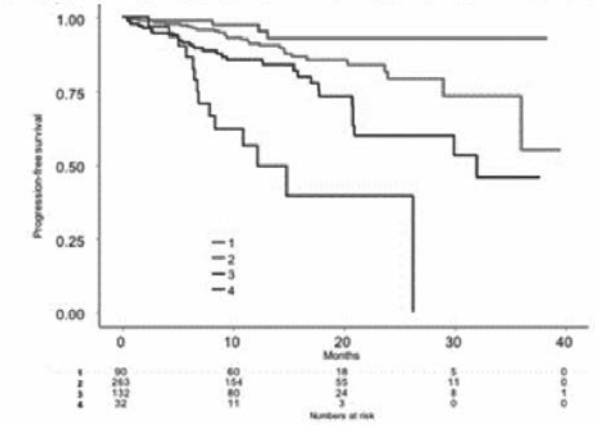

Figure 2.

Summary/Conclusions: The use of a prognostic model based on the mutational status of 9 recurrently mutated genes could improve risk assessment of newly-diagnosed MM patients. Longer follow-up and validation in independent cohorts of patients are needed to confirm our findings. Updated results with a longer follow-up will be presented at the meeting.

P323

TARGETING GENE DEPENDENCY OF 1Q AMPLIFICATION IN MULTIPLE MYELOMA

S. Manier[1,2,*], D. Huynh[2], J. Park[2], K. Salem[2], X. Leleu[3], I. Ghobrial[4]
[1]Hematology, Lille Hospital, Lille, France, [2]Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, [3]Hematology, University of Lille 2, Lille, France, [4]Medical Oncology, Dana-Farber Cancer Institute- Harvard Medical School, Boston, United States

Background: Gain of 1q is one of the most frequent copy number variations across cancer types and in Multiple Myeloma (MM). Gain of 1q is associated with a poor outcome, indicating it is a potential driver in MM progression and resistance to treatment. While the whole 1q arm can be amplified in some cases, a specific minimal amplified region has been identified by CGH array, including approximately 500 genes in the 1q21.1-23.3 region. However, the driver genes in the 1q region are unknown.
Aims: We hypothesize that specific genes present in the 1q minimal amplified region are critical regulators of clonal evolution and tumor progression in MM.
Methods: To explore gene dependency in 1q21.1-23.3 in MM, lung, breast and

ovarian cancers, we performed an shRNA targeted screen, using the C911 technology as a control. We used 14 cell lines including MM, lung, and breast cancer cell lines. We designed a pooled library targeted shRNA/C911 screen containing 6 shRNAs along with their matched control for each of the 500 genes in the 1q21.1-23.3 region, including lncRNA and miRNA in addition to protein coding genes. The pooled library contained 6500 shRNAs, including C911 controls. The differential expression from each shRNA and its own C911 control was calculated and we used the RIGER software to call hits, using the Kolmogorov-Smirnov algorithm. To complement the 1q-targeted shRNA screening, we studied both the Achilles dataset and patients' gene expression profiling from the Multiple Myeloma Genomic portal (MMGP) and the Cancer Genome Atlas (TCGA). Using a list of candidate genes, we then interrogated a large expression-profiling resource developed by the Library of Integrated Network-based Cellular Signatures (LINCS) program to identify potentially active drug targeting our candidate genes. Finally, a targeted drug screening was performed using 179 compounds identified through the LINCS program and using the FDA-approved drug library. Compounds with higher toxicity were further validated in 1q+ (OPM2, H929 and KMS11) and non 1q cell lines (KMS18).
Results: We were able to identify 10 candidate genes, for which knockdown significantly impaired proliferation of gain of 1q cell lines. Several candidate genes were identified as being the top genes preferentially affecting the proliferation of gain of 1q cell lines. To further confirm that our candidate genes are overexpressed in gain of 1q patients, we studied publicly available gene expression profiling from the MMGP and TCGA. Five of the 10 genes were significantly overexpressed in patients with gain of 1q. We then generated a gain of 1q signature by analyzing publicly available gene expression profiling from patients with MM, lung and breast cancers. Each dataset was divided equally into training and validation sets. We identified differentially expressed genes in tumors with gain of 1q *vs* no gain of 1q in these three different cancer types in the training sets. We then combined the three signatures to generate a 'pan-cancer' gain of 1q core signature, which was significantly enriched by using Gene Set Enrichment Analysis (GSEA) in patients with gain of 1q in the validation sets (shown here for MM). We next queried the core signature against the MSigDB 'c2' canonical pathways and 'c3' transcription factor pathways in GSEA and consistently identified a significant enrichment of cell cycle and E2F pathways. A targeted drug screen was then performed using FDA approved drugs and based on specific targets identified in the LINCS database. Compounds that showed high toxicity were further validated in 1q *vs* non 1q+ MM cell lines, and indeed showed significant differential activity of these compounds on 1q *vs* non 1q+ MM cell lines.
Summary/Conclusions: Gain of 1q is one of the defining features of high-risk MM and is associated with adverse outcomes. We developed a systematic approach to determine gene dependencies in gain of 1q MM combining a loss-of-function pooled screen, a computational approach and a drug screen to identify novel therapeutic targets in MM .

P324

DUAL INHIBITION OF DNMT1 AND EZH2 CAN EFFECTIVELY OVERCOME BOTH INTRINSIC AND ACQUIRED RESISTANCE OF MYELOMA CELLS TO IMIDS

K. Dimopoulos[1,*], A. Søgaard Helbo[1], H. Duverger Munch-Petersen[2], L. Sjö[2], J. Christensen[3], F. Asmar[1], P. Gimsing[1], G. Liang[4], K. Grønbæk[1]
[1]Hematology, [2]Pathology, Rigshospitalet, [3]BRIC, Copenhagen, Denmark, [4]Urology, USC, Los Angeles, United States

Background: The introduction of novel agents for the treatment of multiple myeloma (MM), mainly proteasome inhibitors and immunomodulatory agents (IMiDs), has significantly improved the survival rates of the patients, and both classes of drugs stand as the main treatment options for MM. Several studies have identified Cereblon (CRBN) as the direct target of not only thalidomide, but also lenalidomide and pomalidomide, and suggested that its expression is essential for the anti-myeloma effect of these drugs. However, even though the expression levels of CRBN have been associated with response to IMiDs, not all studies have confirmed this finding, as for example patients or cell lines with high levels of CRBN might not exhibit sensitivity to IMiDs. Thus, the expression of CRBN does not consistently explain the lack of IMiD sensitivity and the precise mechanisms behind IMiD resistance still remain elusive.
Aims: The aims of this study were to examine the importance of epigenetic modifications for the expression of CRBN and subsequently the development of IMiD resistance, as well as investigate whether restoration of sensitivity to IMiDs is feasible through epigenetic reprogramming by epigenetic modulators.
Methods: For the development of IMiD-resistant cell lines (OPM2-LR and-PR, H929-LR and -PR), we treated OPM2 and NCI-H929 continuously with increasing doses of either lenalidomide or pomalidomide for 4-6 months, until cell viability and proliferation were not affected. Nucleosome positioning (chromatin accessibility) was assessed using Acce*Sssl*ble, with all the analyses performed in the statistical software R, using the package *minfi*. RNA-seq is currently being performed for OPM2, NCI-H929 their IMiD-resistant as well as resensitized counterparts (N=10) in collaboration with BGI, using BGISEQ500 platform.
Results: Using AcceSsslble, we we found that acquired resistance for both lenalidomide and pomalidomide was primarily associated with a global decrease in chromatin accessibility and to a much lesser extent with DNA methylation changes. Interestingly, neither CRBN nor any of the other molecules involved in the CRBN pathway (IKZF1, IKZF3, IRF4) exhibited changes in either promoter DNA methylation or chromatin accessibility. We then treated the IMiD-resistant cells with the combination of 5-Azacytidine (a DNMT1 inhibitor) and EPZ-6438 (an EZH2 inhibitor) for 48 hours, before exposing the cells again to IMiDs, and found that resistant cells treated with this combination showed increased sensitivity to both lenalidomide and pomalidomide, with significantly increased apoptotic response, similar to the sensitive cell lines. Even more interestingly, we found that the treatment with 5-Aza and EPZ-6438 almost completely restored the global chromatin accessibility changes associated with acquired IMiD resistance back to the initial state, even though the same was not observed for DNA methylation changes. Finally, the combination of 5-Aza and EPZ-6438 was also effective in sensitizing the majority of cell lines with intrinsic resistance to IMiDs. We also observed that treatment with the combination of 5-Aza and EPZ-6438 failed to induce a significant upregulation of CRBN in the IMiD-resistant cell lines, thus suggesting that the process of resensitization to IMiDs is CRBN-independent. Moreover, we show that the degradation of IKZF1 is abrogated on the resistant cell lines, and remains as such despite their resensitization, meaning that the CRBN-IKZF1/IKZF3 pathway might be bypassed and other important regulatory networks might be as important for sensitivity to IMiDs. Therefore, we are currently performing RNA-seq, which might, in combination with accessibility data, give information about the regulatory mechanisms behind acquired IMiD resistance.
Summary/Conclusions: In conclusion, our study is the first one to ever show that acquired IMiD-resistance is mainly an epigenetic event that is potentially reversible through a combination of two epigenetic compounds, 5-Azacitidine and EPZ-6438. These drugs have been shown to have low levels of toxicity, thus making them very good candidates for a prospective phase I study to examine their potential as "IMiD-resensitizers", which may improve the outcome treatment of MM patients with drug-resistant myeloma clones and a potentially high-risk disease.

MULTILAYER EPIGENOMIC ANALYSES REVEAL OF NEW CANDIDATE ONCOGENES INVOLVED IN THE PATHOGENESIS OF MULTIPLE MYELOMA

R. Ordoñez[1,*], M. Kulis[2], N. Russiñol[2], R. Beekman [3], C. Meydan[4], N. Verdaguer-Dot[2], A. Carrasco[1], T. Ezponda[1], J.H. Martens[5], H.G. Stunnenberg[5], B. Paiva[6], J. San Miguel[7], A. Melnick[4], E. Campo[8], F. Prósper[1,7], X. Agirre[1], J.I. Martin-Subero[2]
[1]Oncohematology, Center for Applied Medical Research (CIMA), Pamplona, [2]Departamento de Fundamentos Clínicos, Universitat de Barcelona, [3]Institut-d'InvestigacionsBiomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, [4]Dept. of Medicine, Weill Cornell Medical College, New York, United States, [5]Radboud Institute for Molecular Life Sciences, Nijmegen, Netherlands, [6]Center for Applied Medical Research (CIMA), [7]Clínica Universitaria de Navarra, Pamplona, [8]Hospital Clinic, Barcelona, Spain

Background: Most of the published omics studies in multiple myeloma (MM) have focused on the analysis of the genome, transcriptome and DNA methylome. Over the last years, the chromatin structure and histone modifications are emerging as essential epigenetic layers to understand gene deregulation in cancer, although this field remains widely unexplored in MM.
Aims: We herein aim to elaborate a comprehensive description of the MM epigenome including multiple layers of information.
Methods: We performed ChIP-seq of six histone modifications with non-overlapping functions (H3K4me3, H3K4me1, H3K27ac, H3K36me3, H3K27me3, and H3K9me3), ATAC-seq for chromatin accessibility, Whole Genome Bisulfite Sequencing (WGBS) for DNA methylation, and RNA-seq for gene transcription in purified bone marrow plasma cells from four MM patients and, as healthy controls, naive B cells, germinal center B cells, memory B cells and plasma cells. Data were extensively mined using a battery of different bioinformatic tools.
Results: An initial unsupervised approximation showed that each epigenetic layer cluster MM patient cells separately from normal B cells, which in turn also show differences according to their maturation stage. Moreover, an integrative analysis of ChIP-seq data from six histone marks allowed us to segment the genome into functional chromatin states, such as promoters, enhancers, transcribed regions and repressed/heterochromatic regions. In order to detect regions with significant differences in chromatin activity between MM and normal plasma cells, we elaborated a new algorithm that allowed us to transform the qualitative chromatin state data into a quantitative chromatin activation score (ChromAS). When we compared the ChromAS between MM and normal plasma cells, we detected over 13000 regions with differential activity in MM, from which near 90% were gaining activity in MM, suggesting a widespread activation of their chromatin landscape. To further characterize this phenomenon, we calculated the mean ChromAS per gene and performed a K-means clustering of MM and control cells. Interestingly, we identified the presence of a cluster comprising over 2000 genes whose chromatin was increasing activation in MM as compared to all normal cells. These findings were further validated by ChIP-seq in an additional series of 10 MM patients. We next focused on the genes that gained *de novo* activity in MM and were completely inactive (*i.e.* heterochromatic) in normal

cells. Out of this list, we observed that two adjacent genes, *PRDM5* and *NDNF,* were co-activated in MM. The analysis of their expression in additional patient cohorts indicated that their co-upregulation is a consistent event in MM pathogenesis and that their levels were negligible in bone marrow and tonsillar plasma cells. When analyzing chromatin topology by 4C-Seq, we identified 3D interactions between both gene loci only in MM cells, suggesting that DNA looping between the two genes may be related to their co-activation in MM. Finally, knockdown of each of these genes using inducible shRNAs, decreased cell proliferation and induced apoptosis in MM cells.

Summary/Conclusions: Collectively, our initial exploration of histone modification profiles in MM has revealed an extensive activation of the MM chromatin landscape, which targets new candidate oncogenes. Reversing this global activation by epigenetic drugs, such as BET inhibitors, may represent an attractive therapeutic option for MM.

P326

CLINICAL IMPLICATIONS OF CLONAL CD34+ CELLS IN STEM CELL HARVEST FROM PATIENTS WITH PLASMA CELL DYSCRASIAS

S. Chitre[1,*], F. Stölzel[2], K. Cuthill[1], M. Streetly[1], C. Graham[1], M. Bornhaeuser[2], G. Mufti[1]

[1]Haematological Medicine, KINGS COLLEGE LONDON, London, United Kingdom, [2]Department of Internal Medicine I, University of Dresden, Dresden, Germany

Background: Introduction of novel treatments; Lenalidomide, high-dose alkylating agents (Melphalan) conditioning prior to autologous stem cell transplant (ASCT) over the last few decades has improved overall survival in patients with Multiple Myeloma (MM). In spite of enhanced survival rates, some therapies (especially Lenalidomide maintenance post ASCT) have come under scrutiny for causing therapy related myeloid neoplasms and second primary malignancies (SPM) like Myelodysplastic syndrome (MDS) and Acute myeloid Leukaemia (AML). Clonal haematopoiesis resulting in sequential accumulation of a combination of driver-passenger genetic mutations (in upto 80% of MDS & >95% AML patients) steer MDS/AML disease pathogenesis and clinical outcome. Therefore, we hypothesised that detection of Clonal Hematopoiesis of Indeterminate Potential (CHIP) in haematopoetic stem cells (HSCs) prior to ASCT in patients with MM treated with a range of therapies could be utilised for predicting patients at risk of developing SPMs *i.e.* MDS/AML.

Aims: To ascertain baseline mutational spectrum [especially low-level clones with variant allele frequency (VAF) ≥5%] of MDS/AML associated gene mutations in HSCs prior to ASCT in order to predict patients at risk of clonal evolution, transformation to MDS/AML.

Methods: DNA was isolated from mononuclear cells (MNCs) collected by leucopheresis prior to ASCT from 128 MM patients. A customised amplicon-based Illumina MiSeq panel was used for the sensitive interrogation of 24 most common genes harbouring mutations in MDS/AML (splicing factor genes; *SF3B1*, *SRSF2*, *U2AF1* and *ZRSR2*, genes implicated in epigenetic regulation; *TET2*, *IDH1/2*, *ASXL1*, *EZH2* & *DNMT3A*, known oncogenes/genes involved in cell signalling/transcription regulation and cohesion complex; *TP53*, *FLT3*, *NRAS*, *KRAS*, *ETV6, RUNX1*, *CCBL*, *C-KIT*, *JAK2*, *MPL*, *CEBPA*, *STAG2, GATA2*, KDM6A and *NPM1*). Variant analysis was performed using Illumina Variant Studio (≥5% VAF & read depth ≥150X threshold). To accommodate for the lack of germ line material to confirm the somatic nature of the variants, SNPs occurring at a frequency of ≥0.001% in the healthy population [*e.g.* dbSNP132, UCSC genome browser, Exome sequencing project (esp6500), Exome Aggregation Consortium (ExAc)] were excluded.

Results: Seven patients (6.25%) contained heterozygous somatic mutations (VAF range 7-50%) in *DNMT3A*, *IDH1*, *IDH2*, *TET2*, *ETV6* and *CBL* genes (Table 1). Four missense mutations identified in *DNMT3A* were aggregated in the Mtase domain responsible for its methyltransferase activity indicating a strong intent to abrogate this function. Previous studies confirm R882 variant (accounts for ~ 60% *DNMT3A* mutations) as a founder lesion in MDS/AML strongly associated with clonal haematopoiesis and HSC differentiation. Missense mutation in *CBL* (I429F) has been previously reported in CMML cases *(* while translocations and deletions of *ETV6* are more common in AML M0 (5%) compared to mutations suggesting its role as a tumor-supressor . Genes identified in our cohort are frequently associated with MDS & AML; *IDH1*/*IDH2* (5 & 20%), *TET2* (12 & 20%), *DNMT3A* (8 & 20%) and associated with poor prognosis (*DNMT3A, IDH1/IDH2*). SNP array karyotyping on 4/7 cases (patients 1-4) displayed no chromosomal abnormalities. Median age at diagnosis in these four cases was 65 (range 60-70), long-term follow up (3-5 yrs) revealed relapse of MM in patient 1 and 3, acute kidney injury with myeloma in patient 2 and transformation to AML in patient 4.

Summary/Conclusions: Our data identifies for the first time a subgroup of MM patients (6.25%) with no morphological evidence of MDS/AML prior to ASCT but harbouring CHIP in CD34^{+} harvest stem cells and later developing MDS/AML. These findings are pivotal for identification of such patients at risk of clonal evolution and transformation prior to ASCT since it can be a significant parameter in determining appropriate treatment modality *i.e.* whether or not to employ CHIP harbouring CD34^{+} harvest stem cells as therapy for these patients.

Table 1.

	Gene	VAF (%)	Amino Acid
Patient 1	IDH2	50.8	G145fsX
Patient 2	TET2	9.74	T1149fsX
Patient 3	DNMT3A	14.35	R882H
Patient 4	DNMT3A	7.58	A662V
Patient 5	DNMT3A	13.26	A788G
	DNMT3A	5.24	R676Q
	TET2	7.61	A1882D
	ETV6	16.95	E250K
Patient 6	CBL	21.15	I429F
Patient 7	IDH1	48.53	T106M

Seven patients harbouring mutations in MDS/AML associated genes. Variant allele frequency (VAF) is indicated as a percentage of the total read depth.

P327

PATHOPHYSIOLOGICAL FUNCTIONS AND CLINICAL IMPACT OF THE NEW IMMUNORECEPTOR SLAMF3 IN MULTIPLE MYELOMA

M. Ishibashi[1,*], H. Tamura[1], T. Asayama[1], Y. Kuribayashi-hamada[1], A. Onodera[1], K. Moriya[1], M. Sasaki[2], H. Handa[3], Y. Imai[4], J. Tanaka[5], S. Tanosaki[6], S. Ito[7], K. Inokuchi[1]

[1]Division of Hematology, Department of Medicine, Nippon Medical School, [2]Division of Hematology, Department of Internal Medicine, Juntendo University School of Medicine, Tokyo, [3]Department of Medicine and Clinical Science, Gunma University Graduate School of Medicine, Maebashi, [4]Department of Hematology/Oncology, the Institute of Medical Science, the University of Tokyo, [5]Department of Hematology, Tokyo Women's Medical University, [6]Department of Hematology, Fraternity Memorial Hospital, Tokyo, [7]Department of Medical Oncology, Iwate Medical University School of Medicine, Morioka, Japan

Background: The signaling lymphocytic activation molecule family 3 (SLAMF3) is a member of the immunoglobulin superfamily expressed on T, B, and natural killer cells and modulates the activation and cytotoxicity of these cells via self-ligand binding. SLAMF3 is also expressed on plasma cells from patients with multiple myeloma (MM), although its role in MM pathogenesis remains unclear.

Aims: To clarify this, we investigated the expression and functions of SLAMF3 in MM.

Methods: 1) Two hundred thirty patients comprising 153 newly diagnosed (19 asymptomatic and 134 symptomatic) MM patients, 30 refractory/relapsed MM patients, and 47 patients with monoclonal gammopathy of undetermined significance were enrolled. SLAMF3 and CD138 expression levels on clonal plasma cells were analyzed using flow cytometry (FCM). Soluble SLAMF3 (sSLAMF3) serum levels were measured using ELISA. 2) Drug sensitivity to antimyeloma agents (melphalan and bortezomib) and the proliferation potential in MM cell lines KMS18 and U266 were analyzed using FCM and the MTT assay. SLAMF3 knockdown MM cell lines were obtained using the lentiviral shRNA system and siRNA. Stable transfected KMS34 cell lines overexpressing full-length SLAMF3 and cytoplasmic domain-truncated SLAMF3 (ΔSLAMF3) were established through corresponding vectors. Single-nucleotide polymorphism (SNP) genotyping was analyzed by real-time PCR. The adaptor protein of SLAMF3 was identified by Western blotting and immunoprecipitation.

Results: 1) SLAMF3 was highly expressed on plasma cells in almost all MM patients, even in relapsed/refractory disease, although CD138 expression levels were decreased in some with advanced disease. 2) The proliferative potential and percentage of antimyeloma agent-induced apoptosis in SLAMF3^{high} cells were significantly higher and lower than in SLAMF3^{low} cells, respectively. The cell proliferation and drug resistance in SLAMF3-expressing KMS34 cells were promoted in comparison with ΔSLAMF3 and control cells. That malignant potential in MM cells was cancelled by SLAMF3 knockdown. Furthermore, the proliferation of MM cells and resistance to antimyeloma agents were inhibited by anti-SLAMF3 antibody. Adaptor proteins, SHP2 and GRB2, were expressed in MM cell lines, but neither SAP nor EAT-2 were. SLAMF3 interacted directly with SHP2 and GRB2, and SHP2 also interacted with GRB2. SHP2 inhibitor-treated or SHP2/GRB-knockdown cells had characteristics similar to SLAMF3-knockdown cells. 3) The frequency of GG genotypes of SLAMF3 SNP rs509749 in MM patients was 63.6% (n=28), of AG 29.5% (n=13), and of AA 6.8% (n=3). Patients with GG genotypes tended to have shorter overall survival times than patients with AG genotypes. 4) sSLAMF3 levels were significantly higher in symptomatic MM than in asymptomatic MM and markedly increased in advanced MM. MM patients with high levels (≥3.3 ng/ml, n=62) of sSLAMF3 progressed to the

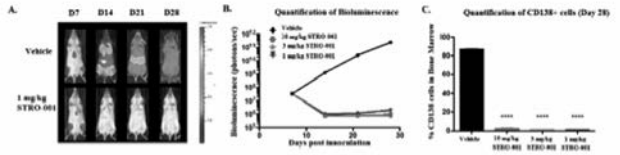
advanced stage significantly more often and had shorter progression-free survival times than those with low levels (<3.3 ng/ml, n=32) (P=0.032).
Summary/Conclusions: This study revealed that SLAMF3 molecules consistently expressed on MM cells may transmit positive signals mediated via the complex of SHP2 and GRB2 by self-ligand interaction between MM cells and induce a high malignant potential in MM. Furthermore, high levels of serum sSLAMF3 may reflect MM disease progression and be a useful prognostic factor in MM. Thus, SLAMF3 molecules may be a new potential target for future immunotherapy and chemotherapy.

P328

TARGETING CD74 IN MULTIPLE MYELOMA WITH A NOVEL ANTIBODY DRUG CONJUGATE, STRO-001

M. Embry[1], X. Li[1], V. DeAlmeida[1], C. Abrahams[1], A. Yu[1], S. Krimm[1], S. Krueger[2], S. Matheny[1], T. Kline[1], A. Yam[1], R. Stafford[1], T. Hallam[1], M. Lupher[1], A. Molina[1,*]
[1]Sutro Biopharma, South San Francisco, [2]MI Bioresearch, Ann Arbor, United States

Background: CD74 is a transmembrane glycoprotein involved in MHC protein formation and transport. CD74 expression has been observed in up to 90% of B-cell malignancies, including multiple myeloma (MM), with minimal expression in normal tissues. CD74 is rapidly internalized, making it an attractive target for ADCs. STRO-001 is a novel ADC comprised of an aglycosylated anti-CD74 IgG1 human antibody (SP7219) conjugated covalently to the non-natural amino acid para-azido-methyl-L-phenylalanine (pAMF) with a non-cleavable dibenzocyclooctyne (DBCO)-maytansinoid linker-warhead. Highly efficient site-specific conjugation enabled by novel cell-free antibody production and click chemistry results in a well-defined homogeneous ADC drug product with a drug-antibody ratio (DAR) of 2.
Aims: The *in vitro* cytotoxicity and *in vivo* efficacy of STRO-001 was investigated in MM cell lines and xenografts. An exploratory toxicology study was conducted in a non-human primate model.
Methods: DBCO-Alexa647-conjugated SP7219 staining and flow cytometry were used for detection and quantitation of CD74 expression on MM cell lines. STRO-001 was used to determine the EC_{50} and percent span of killing in MM cell lines. The anti-tumor activity of STRO-001 was evaluated in the disseminated ARP-1 and MM.1S MM models. *In vivo* bioluminescence imaging (BLI) for animals bearing MM.1s-luc cells was performed using an IVIS Spectrum. BLI images were collected 7, 14, 21, and 28 days post-tumor cell inoculation. STRO-001 was administered to cynomolgus monkeys in an exploratory dose-escalating study of repeat IV doses of 1, 3, 10 and 30 mg/kg on days 1 and 15.
Results: *In vitro* cytotoxicity assays show nanomolar potency of STRO-001 in five MM cell lines: MC/CAR (EC_{50} 0.8 nM), ARD (EC_{50} 6.5 nM), MM.1S (EC_{50} 10-11 nM), U266B1 (EC_{50} 8.5-9.3 nM), and ARP-1 (EC_{50} 4.3-22 nM). CD74 cell surface expression is required for STRO-001 cytotoxic activity but expression level, as measured by antibody-binding capacity, does not correlate strongly with *in vitro* potency (R^2=0.5837 for MM cell lines). STRO-001 inhibits the growth of CD138+ plasma cells in bone marrow (BM) and formation of visceral tumors (p=0.002 for kidney; p<0.0001 for ovary) after 4 weekly doses of 3 mg/kg in the ARP-1 disseminated MM xenograft model. STRO-001 dosed at 3 mg/kg and 10 mg/kg weekly x 3 also eradicates malignant BM plasma cells by day 32 post-inoculation (p<0.0001) and prolongs survival in the MM.1S disseminated model. At termination of the study, 129 days post-inoculation, 100% of the STRO-001 treated animals survived and showed no evidence of disease with no CD138+ cells in their bone marrow, while mean survival of vehicle-treated control animals was 35 days with almost 50% of their bone marrow containing myeloma cells. BLI of luciferase-expressing MM.1S (MM.1S-luc) tumor cell lines enabled non-invasive quantitation of tumor burden. Single doses of 1, 3, and 10 mg/kg STRO-001 (administered on day 7 post-inoculation) resulted in eradication of myeloma by day 28 based on bioluminescence signal and quantification of CD138+ cells in bone marrow. In addition, STRO-001 produced a dose-dependent reduction in normal B-cells in cynomolgus monkeys, providing pharmacodynamic evidence of B-cell targeting (Figure 1).



NSG mice inoculated with MM.1S-luc cells received a single dose of vehicle, 1, 3, or 10 mg/kg STRO-001 at 7 days post-inoculation. (A) Representative *in vivo* images of luminescence showing MM.1S-luc cells in the bone marrow of live mice treated with vehicle or 1 mg/kg STRO-001 at different time points. (B) Quantification of bioluminescence in live mice treated with vehicle, 1 mg/kg STRO-001, 3 mg/kg STRO-001 and 10 mg/kg STRO-001. (C) Quantification of CD138+ cells in the bone marrow of mice treated with vehicle, 1 mg/kg STRO-001, 3 mg/kg STRO-001 and 10 mg/kg STRO-001 on day 28 post-inoculation. Asterisks indicate significant difference compared to control (****, p<.0001).

Figure 1.

Summary/Conclusions: STRO-001 demonstrates potent *in vitro* cytotoxicity in MM cell lines and reduces tumor burden in MM xenograft models, including significant prolongation of survival in the MM.1S model. Based on these encouraging observations, STRO-001 is advancing to the clinic for the treatment of CD74-expressing B-cell malignancies.

P329

GENOTYPE CHARACTERIZATION OF LIGHT CHAIN AMYLOIDOSIS BY WHOLE EXOME SEQUENCING

I. Cuenca[1,*], B. Sánchez-Vega[1], B. Paiva[2], M. Gallardo[1], L.A. Corchete[3], I. Rapado[1], N. Puig[3], S. Barrio[1], D. Alignami[2], M. Lasa[2], A. García de Coca[4], M.-L. Sanchez[3], E. Pardal[5], A. Oriol[6], M.-E. Gonzalez Garcia[7], F. Escalante[8], T.J. González-López[9], L. Palomera[10], J. Alonso[11], F. Prosper[12], A. Orfao[3], M.-B. Vidriales[3], M.-V. Mateos[3], N.C. Gutierrez[3], J.-J. Lahuerta[1], J.F. San Miguel[2], J. Martínez-López[1]
[1]Hematología traslacional, Hospital 12 de Octubre, Madrid, [2]Centro de Investigacion Medica Aplicada, Pamplona , [3]Hospital Universitario de Salamanca, Instituto de Investigacion Biomedica de Salamanca (IBSAL), Centro de Investigación del Cancer (IBMCC CSIC-USAL), Salamanca, [4]Hospital Clínico Universitario de Valladolid, Valladolid , [5]Hospital Virgen del Puerto, Plasencia, [6]Hospital German Trias i Pujol, Badalona, [7]Hospital de Cabueñes, Gijón, [8]Complejo Hospitalario de León, León, [9]Hospital Universitario de Burgos, Burgos, [10]Hospital Clinico Universitario Lozano Blesa, Zaragoza, [11]Hospital Río Carrión, Palencia, [12]Clínica Universidad de Navarra, Pamplona, Spain

Background: Immunoglobulin light-chain amyloidosis (AL) is a heterogeneous and multifactorial disease with high genetic complexity. Until now, no common factor o unique mutation associated with this disease has been described. Whole exome sequencing in Multiple Myeloma (MM) patient's tests allowed to known important genes and pathways that are involved in the disease. However, few evidences through next generation sequencing (NGS) analysis were described in AL. Consequently, the application of NGS technologies permits unraveling the genomic landscape of AL to better disentangle the biology of the disease, allowing the identification of new therapeutic targets as in MM.
Aims: Genotype characterization of novel molecular alterations in AL plasma cell by whole-exome sequencing technology.
Methods: We studied 40 paired samples (sorted pathological plasma cells and peripheral blood) from 20 patients with AL. Whole exome and regulatory regions were captured using Agilent's SureSelect Human All Exon V6+UTR kit and sequenced on the Illumina NextSeq 500 platform with pair-end sequencing technique with a global mean depth coverage of 70x, on target coverage of 96.5% and a Phred quality score of 91.3% up to Q30. Data were analyzed with Strelka software to discard germinal mutations, wANNOVAR for functional annotation, and a data reduction strategy to identify candidate variants.
Results: After analysis of patient samples we got an average of 76 (range 18-177) mutations per patient. 28.4% of the mutations was located on regulatory regions (5' UTR, 3' UTR). So far, we did not identify recurrent mutations between the patients, although some patients presented different mutations on the same gene.
The mutation pattern was very heterogeneous between patients. We identified alterations in genes involved in extracellular matrix (MMP2), cell proliferation, differentiation and development (TFGA), transcription factors (ZFHX3, HNRPNPL), adherent junction function (RASSF8), GTPases (RAPGEF2, RAB40A), and genes of the collagenase family (COL9A1, COL1A2) among others.
Summary/Conclusions: Taken together, these results suggest that the mutation pattern in AL is heterogeneous with no common mutated gene among all patients. However, we described novel mutations in the context of AL in regulatory genes or over-representing cancer-related pathways that can help to elucidate the molecular biology of the disease.

Myeloma and other monoclonal gammopathies - Clinical 1

P330

IMPROVED SURVIVAL IN 21,465 MULTIPLE MYELOMA PATIENTS: RESULTS FROM A POPULATION-BASED STUDY

S. Thorsteinsdottir[1,*], P.W. Dickman[2], I. Turesson[3], O. Landgren[4], M. Hultcrantz[5,6], M. Björkholm[5], S.Y. Kristinsson[1,5]
[1]Department of Internal Medicine, Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland, [2]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, [3]Department of Hematology and Coagulation Disorders, Skane University Hospital, Malmö, Sweden, [4]Myeloma Service, Division of Hematologic Oncology, Memorial Sloan-Kettering Cancer Center, New York, United States, [5]Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, [6]Myeloma Service, Division of Hematologic Oncology, Memorial Sloan-Kettering Cancer Center, New York, Sweden

Background: Multiple myeloma (MM) is generally considered an incurable disease, however advances in the treatment options for MM have been great in recent years. Recent studies on these new agents indicate an improvement in survival, nevertheless population-based studies have had contradicting findings, especially in the elderly patients.
Aims: The aim of the study was to evaluate the survival of all patients diagnosed with MM in Sweden in the years 1973 to 2013 and to relate the survival pattern to trends in treatment strategies.
Methods: Patients diagnosed with MM in the period from January 1, 1973 to December 31, 2013 were identified from the Swedish Cancer Registry. Information on sex, date of birth, date of diagnosis, and date of death was collected. Relative survival ratios (RSRs) were used to provide a measure of excess mortality of MM patients compared to a comparable group from the general population. RSRs with 95% confidence intervals (Cis) were found for 1-, 5-, and 10-years for 4 calendar periods; 1973-1982, 1983-1992, 1993-2002, and 2003-2013 and furthermore for 6 age categories at diagnosis (0-40, 41-50, 51-60, 61-70, 71-80 and >80). Short-term survival, as defined by RSR of less than 3 months, was also defined for all calendar periods.
Results: A total of 21,465 patients (54% males, median age at diagnosis 72 years) with MM were recorded in the time period. Overall, the 1- and 5- and 10-year RSRs improved in the whole period, with the greatest improvement in the two most recent calendar periods. The 1-year RSR increased significantly between all calendar periods (0.69, 0.74, 0.77 and 0.82, respectively). The 5-year RSR increased significantly between the two last calendar periods (0.28, 0.31, 0.33 and 0.41, respectively; Figure 1) as well as the 10-year RSR (0.10, 0.12, 0.14 and 0.20, respectively). Short-term survival increased significantly between the first two and last two calendar periods (the RSR were 0.83, 0.88, 0.89 and 0.93 respectively). Females had a lower excess mortality compared to males (excess mortality ratio 0.91).

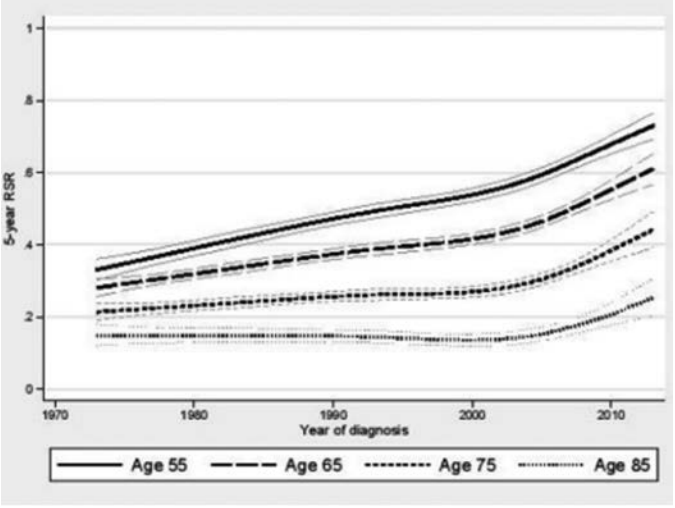


Figure 1.

Summary/Conclusions: In this population-based study, based on more than 21,000 MM patients diagnosed during more than a 40-year period, we showed that with an increased use of novel agents in MM patients, survival has improved significantly. This is especially prominent during the last 10 years. Our findings are important, since new agents are approved based on clinical trials, where certain groups, such as older patients and patients with significant comorbidities are often excluded.

P331

PROGNOSTIC IMPLICATIONS OF MULTIPLE CYTOGENETIC HIGH-RISK ABNORMALITIES IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

M. Binder[1,*], S.V. Rajkumar[2], R.P. Ketterling[3], A. Dispenzieri[2], M.Q. Lacy[2], M.A. Gertz[2], F.K. Buadi[2], S.R. Hayman[2], Y.L. Hwa[2], S.R. Zeldenrust[2], J.A. Lust[2], S.J. Russell[2], N. Leung[24], P. Kapoor[2], R.S. Go[2], W.I. Gonsalves[2], R.A. Kyle[2], S.K. Kumar[2]
[1]Department of Internal Medicine, [2]Division of Hematology, [3]Department of Laboratory Medicine and Pathology, [4]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, United States

Background: Cytogenetic evaluation using fluorescence *in situ* hybridization (FISH) at the time of diagnosis is essential for initial risk stratification in multiple myeloma. The presence of specific cytogenetic high-risk abnormalities (HRA) is known to confer a poor prognosis, less is known about the cumulative effect of multiple such abnormalities.
Aims: To evaluate the prognostic implications of the presence of multiple HRA at the time of diagnosis.
Methods: We studied 1181 patients who were diagnosed with multiple myeloma between July 2005 and July 2015 at Mayo Clinic Rochester, underwent FISH evaluation within 6 months of diagnosis, and received first-line therapy with at least 1 novel agent (immunomodulator or proteasome inhibitor). HRA were defined as t(4;14), t(14;16), t(14;20), del(17p), and gain(1q). Bone marrow aspirates were evaluated for deletions, monosomies, trisomies, and tetrasomies using chromosome- or centromere-specific FISH probes. IGH rearrangements were evaluated using an IGH break-apart probe and evaluating up to 5 potential partners (FGFR3, CCND1, CCND3, MAF, and MAFB). Kaplan-Meier overall survival estimates were calculated and the log-rank test was used to compare overall survival in patients with and without HRA (stratified by the number of HRA). A multivariable-adjusted Cox regression model was used to assess the effect of HRA on overall survival adjusting for age, sex, International Staging System (ISS) stage, and first-line therapy (immunomodulator, proteasome inhibitor, upfront autologous hematopoietic stem cell transplantation). Patients diagnosed after 2014 (approximately 15% of the cohort) routinely underwent evaluation for gain(1q), therefore the hazard ratios represent conservative effect estimates. P-values below 0.05 were considered statistically significant.
Results: The median age at diagnosis was 65 years (28 - 95), 708 (60%) of the patients were male. There were 375 HRA in 327 patients (28% of the cohort): 170 (45%) del(17p), 110 (29%) t(4;14), 45 (12%) t(14;16), 8 (2%) t(14;20), and 42 (12%) gain(1q). Of the 280 patients with 1 HRA 130 (46%) had del(17p), 120 (43%) had a high-risk translocation, and 30 (11%) had gain(1q). Of the 46 patients with 2 HRA 34 (76%) had del(17p) and a high-risk translocation, 6 (13%) had a high-risk translocation and gain(1q), 5 (11%) had del(17p) and gain(1q), and 1 had 2 high-risk translocations. There was 1 patient with 3 HRA: del(17p) and t(4;14) and gain(1q). The median overall survival was 6.6 years (6.0 - 8.0) for the entire cohort (n=1181), 8.3 years (6.7 - 8.9) for those without HRA (n=854, 72%), 4.9 years (3.9 - 5.6) for those with one HRA (n=280, 24%), and 2.7 years (2.1 - 3.8) for those with 2 or more (2+) HRA (n=47, 4%). Figure 1 shows the Kaplan-Meier overall survival estimates stratified by the number of HRA (n=1181). The presence of 1 HRA (*versus* 0, HR 1.57, 95% CI 1.26 - 1.96, p <0.001, n=1181) and the presence of 2+ HRA (*versus* 1, HR 3.37, 95% CI 2.21 - 5.14, p <0.001, n=1181) were of prognostic significance after adjusting for age, sex, ISS stage, and first-line therapy. When adjusting for the revised ISS instead of the ISS the hazard was attenuated for 1 HRA (*versus* 0, HR 1.42, 95% CI 1.12 - 1.80, p=0.004, n=1087) and 2+ HRA (*versus* 1, HR 2.82, 95% CI 1.81 - 4.40, p <0.001, n=1087).

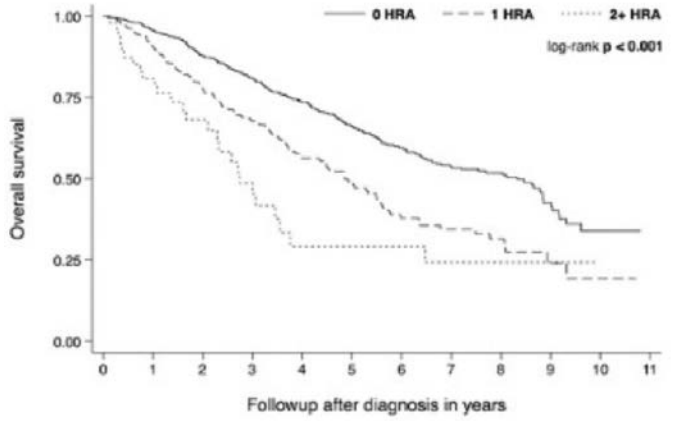

Figure 1.

Summary/Conclusions: Approximately 1 in 4 patients with newly diagnosed multiple myeloma presented with 1 HRA at the time of diagnosis, approximately 1 in 25 with 2 or more HRA. These patients experienced inferior overall survival suggesting a cumulative effect of multiple HRA.

P332

LENALIDOMIDE MAINTENANCE VS PLACEBO AFTER STEM CELL TRANSPLANT FOR PATIENTS WITH MULTIPLE MYELOMA: OVERALL SURVIVAL AND PROGRESSION-FREE SURVIVAL AFTER ADJUSTING FOR TREATMENT CROSSOVER IN CALGB

P.L. McCarthy[1,*], S.A. Holstein[2], S.-H. Jung[3], M. Cooper[4], C.J. Gibson[5], E.A. Stadtmauer[6], B. Winograd[5], P. Richardson[7]
[1]Blood and Marrow Transplant Program, Roswell Park Cancer Institute, Buffalo, NY, [2]University of Nebraska Medical Center, Omaha, NE, [3]Alliance Statistics and Data Center, Duke University, Durham, NC, United States, [4]BresMed, Sheffield, United Kingdom, [5]Celgene Corporation, Summit, NJ, [6]Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA, [7]Dana-Farber/Partners CancerCare, Boston, MA, United States

Background: At a prespecified interim analysis (December 2009), the phase 3 CALGB/ECOG 100104 (Alliance) study results surpassed the prespecified superiority boundary (significantly improved progression-free survival [PFS] for lenalidomide [LEN] maintenance *vs* placebo [PBO] after SCT) and the majority of PBO arm patients without progressive disease (PD) crossed over to LEN maintenance. An updated analysis (cutoff March 2015), showed significantly longer overall survival [OS] with LEN maintenance (HR, 0.56; 95% CI, 0.42-0.76). However, the crossover from PBO to LEN makes it difficult to assess the true treatment effect of LEN.
Aims: To examine the effect of LEN *vs* PBO on OS and PFS from randomization, adjusting for effects of crossover.
Methods: The rank-preserving structural failure time model (RPSFTM; Robins, *Commun Stat Theory Methods*, 1991) was used for crossover adjustment; the iterative parameter estimation (IPE; Branson, *Stat Med*, 2002) algorithm was used as validation. Survival was partitioned assuming a residual LEN effect after discontinuation. A landmark analysis was also performed at the Dec 2009 interim for patients who remained on treatment. Patients in the trial provided informed consent.
Results: Patients were randomized to LEN maintenance (n=231) and PBO (n=229) (intent-to-treat [ITT] population); 76 patients without PD crossed over from PBO to LEN. The median time from randomization to crossover was 11.5 months. The relative treatment effect for OS and PFS increased for LEN *vs* PBO when adjusting for crossover using RPSFTM and IPE (Table 1). The landmark analysis at the Dec 2009 interim (PBO crossover, n=76; No crossover, n=34) showed the treatment effect is not dissimilar to the ITT analysis (HR 0.53; 95% CI, 0.25-1.13). Sensitivity analyses showed consistent results. Updated data will be presented at the meeting.

Table 1.

	OS[a]	PFS[a]
	LEN (n = 231) vs PBO (n = 229)	
ITT, Unadjusted	NR vs 79.0 0.56 (0.42-0.76)	58.4 vs 28.9 0.58 (0.46-0.73)
RPSFTM	NR vs 70.9 0.48 (0.34-0.69)[b]	58.4 vs 25.8 0.50 (0.39-0.63)[b]
IPE	NR vs 70.9 0.48 (0.33-0.68)[b]	58.4 vs 25.8 0.48 (0.36-0.64)[b]

[a]Data are median, months; HR (95% CI). [b]Bootstrapped 95% CI.

Support: U10CA180821, U10CA180882, CA180820. **ClinicalTrials.gov Identifier:** NCT00114101

Summary/Conclusions: Adjusting for the potential diluting effects of crossover reduced median OS and PFS with PBO, and improved the treatment effect in the ITT analyses for OS and PFS for LEN *vs* PBO maintenance after SCT. The statistical significance of the ITT analyses was maintained throughout.

P333

UPDATED RESULTS FROM ASPIRE AND ENDEAVOR, RANDOMISED, OPEN-LABEL, MULTICENTRE PHASE 3 STUDIES OF CARFILZOMIB IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

D. Siegel[1,*], A. Oriol[2], P. Rajnics[3], J. Minarik[4], V. Hungria[5], J.H. Lee[6], K. Song[7], M. Obreja[8], S. Aggarwal[8], R. Hajek[9]
[1]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, United States, [2]Institut Català d'Oncologia and Institut Josep Carreras, Hospital Germans Trias i Pujol, Barcelona, Spain, [3]Department of Hematology, Mor Kaposi Teaching Hospital, Kaposvar, Hungary, [4]Department of Hemato-Oncology, University Hospital Olomouc and Faculty of Medicine and Dentistry, Olomouc, Czech Republic, [5]Irmandade da Santa Casa de Misericórdia de Sao Paulo, Sao Paulo, Brazil, [6]Gachon University Gil Medical Center, Incheon, Korea, Republic Of, [7]Leukemia/Bone Marrow Transplant Program, Division of Hematology, University of British Columbia, Vancouver, Canada, [8]Amgen Inc., Thousand Oaks, United States, [9]University Hospital Ostrava, Ostrava, Czech Republic

Background: In RRMM, carfilzomib, lenalidomide, and dexamethasone (KRd) was superior to Rd in ASPIRE (Stewart, N Engl J Med. 2015), and carfilzomib and dexamethasone (Kd) was superior to bortezomib and dexamethasone (Vd) in ENDEAVOR (Dimopoulos, Lancet Oncol. 2016) for the primary endpoint of progression-free survival (PFS) by independent review.
Aims: To report safety and efficacy data after 6-7 months of additional follow-up.
Methods: Adults with RRMM who received 1–3 prior regimens were randomised 1:1. In ASPIRE, patients received lenalidomide (25 mg) on days 1–21 and dexamethasone (40 mg) on days 1, 8, 15, and 22 (28-day cycle). KRd patients received carfilzomib on days 1, 2, 8, 9, 15, and 16 during cycles 1–12 (20 mg/m^2 [days 1 and 2 of cycle 1]; 27 mg/m^2 thereafter); carfilzomib was omitted on days 8 and 9 in cycles 13–18. In ENDEAVOR, Kd patients received carfilzomib (20 mg/m^2 on days 1 and 2 of cycle 1; 56 mg/m^2 thereafter) on days 1, 2, 8, 9, 15, and 16 and dexamethasone (20 mg) on days 1, 2, 8, 9, 15, 16, 22, and 23 (28-day cycle). In the Vd group, bortezomib was given (1.3 mg/m^2; intravenously or subcutaneously) on days 1, 4, 8, and 11, and dexamethasone (20 mg) on days 1, 2, 4, 5, 8, 9, 11, and 12 (21-day cycle). Comparisons were per stratified log-rank test; data presented here are per investigator assessment.
Results: In ASPIRE, 792 patients were randomised. Baseline characteristics were balanced between arms. At a median follow-up of 37.8 months (KRd) and 37.0 months (Rd), median PFS was 26.1 months (KRd) and 16.6 months (Rd) (hazard ratio [HR]: 0.67; 95% confidence interval [CI]: 0.56–0.80; P <0.0001); 18-month PFS rates were 64.5% (KRd) and 46.6% (Rd). Median time to progression (TTP) was 30.5 months (KRd) and 18.9 months (Rd) (HR: 0.62; 95% CI: 0.51–0.76; P <0.0001). Median time to next treatment (TTNT) was not estimable (KRd) and 24.3 months (Rd) (HR: 0.62; 95% CI: 0.50–0.77; P <0.0001). 16.8% (KRd) and 19.0% (Rd) of patients discontinued because of adverse events (AEs). Grade ≥3 AE rates were 5.9% and 2.2% for hypertension, 3.9% and 1.8% for cardiac failure, and 4.6% and 5.4% for peripheral neuropathy for KRd and Rd, respectively. In ENDEAVOR, 929 patients were randomised. Baseline characteristics were balanced between arms. At a median follow-up of 19.4 months (Kd) and 17.7 months (Vd), median PFS was 17.6 months (Kd) and 9.4 months (Vd) (HR: 0.53; 95% CI: 0.44–0.63; P <0.0001); 18-month PFS rates were 48.7% (Kd) and 23.9% (Vd). Median TTP was 19.4 months (Kd) and 10.2 months (Vd) (HR: 0.50; 95% CI: 0.42–0.60; P <0.0001). Median TTNT was 26.1 months (Kd) and 14.5 months (Vd) (HR: 0.49; 95% CI: 0.40–0.60; P <0.0001). 15.8% (Kd) and 14.9% (Vd) of patients discontinued because of AEs. Grade ≥3 AE rates were 13.8% and 3.3% for hypertension, 5.2% and 2.0% for cardiac failure, and 2.4% and 8.6% for peripheral neuropathy for Kd and Vd, respectively.
Summary/Conclusions: Consistent with the primary analyses, these results show that incorporation of carfilzomib into treatment regimens in patients with RRMM results in clinically meaningful improvements in PFS and a favourable benefit-risk profile.

P334

EFFICACY AND SAFETY OF DARATUMUMAB, LENALIDOMIDE, AND DEXAMETHASONE VERSUS RD ALONE IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA: UPDATED ANALYSIS OF POLLUX

Background: Daratumumab, a human monoclonal antibody targeting CD38, significantly prolongs progression-free survival (PFS) and achieves deep and durable responses when combined with other established standard-of-care regimens in patients with RRMM.
Aims: To provide updated efficacy and safety data from POLLUX, a multicenter, phase 3, randomized study of DRd *versus* Rd in RRMM.
Methods: Eligible patients with ≥1 prior line of therapy were randomly assigned to Rd (25 mg PO lenalidomide on Days 1-21 of each every-4-week [Q4W] cycle; 40 mg dexamethasone weekly) with or without daratumumab (16 mg/kg IV once weekly for Cycles 1 and 2, every 2 weeks for Cycles 3-6, then Q4W until disease progression). Patients who were refractory to lenalidomide were excluded. Progression-free survival (PFS) was the primary endpoint. Bone

marrow samples were collected, and minimal residual disease (MRD) was assessed at the time of suspected complete response (CR) and at 3 and 6 months after suspected CR at 3 different sensitivity thresholds (10^{-4}, 10^{-5}, and 10^{-6}) using the ClonoSEQ™ next-generation sequencing-based assay (Adaptive Biotechnologies, Seattle, WA). Additional reflex testing using an anti-idiotype antibody was used to confirm CRs in cases in which daratumumab interference with serum M-protein quantitation was suspected in patients with possible CR.

Results: Patients received a median (range) of 1 (1-11) prior lines of therapy; 55% of patients had received immunomodulatory agents (IMIDs), and 18% had been exposed to lenalidomide. After median follow-up of 17.3 months, DRd significantly prolonged PFS compared with Rd alone (median: not reached *vs* 17.5 months; hazard ratio [HR], 0.37; 95% confidence interval [CI], 0.28-0.50; *P*<0.0001), with 18-month PFS rates of 76% and 49%, respectively. Responses continued to deepen in the DRd group with longer follow-up, with significantly higher overall response rate (ORR; 93% *vs* 76%) and rates of very good partial response (VGPR) or better (78% *vs* 45%) and CR or better (46% *vs* 20%) with DRd *versus* Rd alone (*P*<0.0001 for all). MRD-negative rates were >3 times higher with DRd compared with Rd alone at all 3 sensitivity thresholds (31.8% *vs* 8.8% at 10^{-4}; 24.8% *vs* 5.7% at 10^{-5}; and 11.9% *vs* 2.5%, at 10^{-6}; *P*<0.0001 for all), and MRD negativity was associated with prolonged PFS at 10^{-5} (Figure 1). Overall survival (OS) data are immature, with 40 (14%) deaths in the DRd group and 56 (20%) deaths in the Rd group (HR, 0.63; 95% CI, 0.42-0.95). Neutropenia was the most common grade 3 or 4 treatment-emergent adverse event (53% with DRd *vs* 38% with Rd), and no new safety signals were reported with longer follow up. We will present updated efficacy and safety data based on approximately 25 months follow up at the meeting.

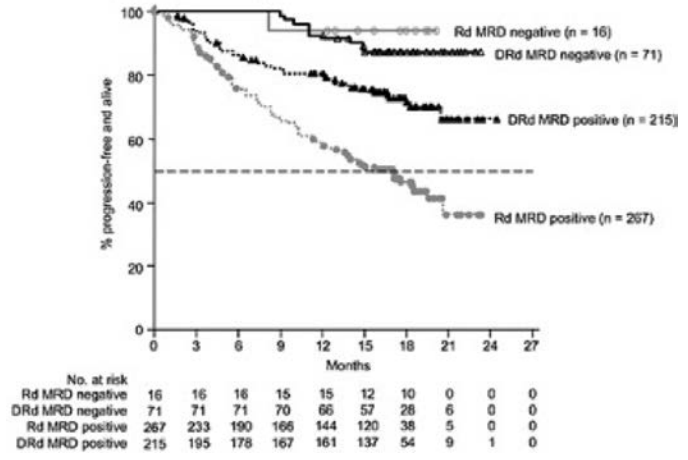

Figure 1.

Summary/Conclusions: DRd significantly improved outcomes compared with Rd alone, including PFS, ORR, depth of response, and MRD-negative rates, with a favorable safety profile that was maintained after longer follow up. These updated data continue to support the use of DRd in patients with RRMM who received ≥1 prior therapy.

Background: Daratumumab (D) used in combination with bortezomib and dexamethasone (Vd; CASTOR) or lenalidomide and dexamethasone (Rd; POLLUX) significantly prolongs progression-free survival (PFS) with a manageable safety profile compared with either Vd or Rd alone in patients (pts) with RRMM.

Aims: Here in this subgroup analysis we investigated the safety and efficacy of DVd and DRd in elderly pts aged ≥75 years from the CASTOR and POLLUX phase 3 studies.

Methods: Overall, pts enrolled in the CASTOR and POLLUX studies had ≥1 prior line of therapy. Pts in CASTOR received up to 8 cycles of Vd with or without D; pts in the DVd group then continued to receive D monotherapy q4w until disease progression or unacceptable toxicity. Pts in POLLUX were treated until progression. Dosing schedules for D (16 mg/kg) were different between CASTOR (qw in Cycles 1-3, q3w for Cycles 4-8, and q4w thereafter) and POLLUX (qw for Cycles 1-2, q2w for Cycles 3-6, and q4w thereafter). All elderly pts received a reduced dose of dexamethasone (20 mg once weekly *vs* 40 mg once weekly) in both studies.

Results: In CASTOR, 23/251 pts in the DVd group and 35/247 pts in the Vd group were ≥75 years; the median (range) age for this group of pts was 78 (75-88) and 78 (75-85) years, respectively, with 100% and 94% with an ECOG status ≤1. At a median follow-up of 13.0 months, discontinuation rates due to treatment-emergent adverse events (TEAEs) were similar with DVd and Vd (15% *vs* 20%). Common (≥10%) grade 3/4 TEAEs for DVd were thrombocytopenia (45% *vs* 37% with Vd), fatigue (15% *vs* 11%), pneumonia (15% *vs* 17%), and anemia (10% *vs* 11%). Infusion-related reactions (IRR) occurred in 13 (65%) pts, with 10% having grade 3/4 IRR, but no pts discontinued due to IRR. Median PFS was significantly prolonged with DVd *versus* Vd (not reached [NR] *vs* 8.1 months; hazard ratio [HR], 0.27; 95% confidence intervals [CI], 0.12-0.61; P=0.0007), consistent with the overall PFS observed in CASTOR (Figure). Higher overall response rate (ORR; 95% *vs* 79%) and rates of complete response (CR) or better (25% *vs* 3%) and very good partial response (VGPR) or better (70% *vs* 18%) were achieved with DVd *versus* Vd, respectively, consistent with the overall population. In the POLLUX study, 29/286 pts in the DRd group and 35/283 pts in the Rd group were aged ≥75 years; the median (range) age for this group of pts was 77 (75-89) and 78 (75-87) years, respectively, with 86% and 91% with an ECOG status ≤1. At a median follow-up of 17.3 months, 10% of pts in the DRd group and 11% in the Rd group discontinued due to TEAEs. Common (≥10%) grade 3/4 TEAEs for DRd were neutropenia (45% *vs* 31% with Rd), hypokalemia (14% *vs* 3%), and pneumonia (10% *vs* 11%). D-associated IRR occurred in 12 (41%) pts in the DRd group, with 4 (14%) pts having grade 3/4 IRR. No patient discontinued DRd because of IRR. Median PFS was significantly prolonged with DRd compared with Rd in the elderly subgroup (NR *vs* 11.4 months; HR, 0.19; 95% CI, 0.06-0.55; P=0.0007), consistent with the overall PFS observed in POLLUX (Figure 1). ORR was higher with DRd *versus* Rd (93% *vs* 77%), and rates of CR or better (52% *vs* 9%) and VGPR or better (72% *vs* 41%) were also higher with DRd *versus* Rd.

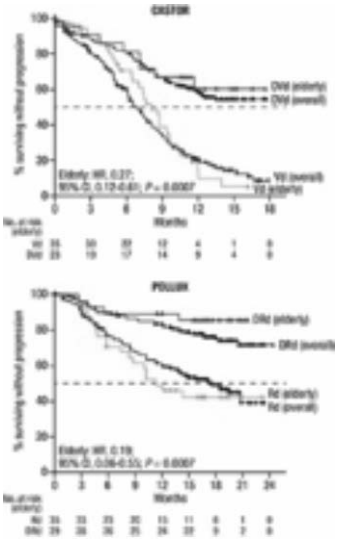

Figure 1.

Summary/Conclusions: The results in elderly pts were consistent with those observed in the overall study populations in terms of efficacy. Rates of most common grade 3/4 hematologic TEAEs in elderly pts were similar to that of the overall populations, and IRR were manageable. This subgroup analysis supports the addition of D to standard-of-care regimens in elderly pts with RRMM.

P336

ALL ORAL COMBINATION OF IXAZOMIB PLUS THALIDOMIDE AND DEXAMETHASONE FOR RELAPSED OR REFRACTORY MULTIPLE MYELOMA: INTERIM DATA OF AN ONGOING PHASE II TRIAL

Background: Ixazomib is a novel, effective oral proteasome inhibitor with a favorable toxicity profile. Recent studies showed significant activity as single agent with dexamethasone and in combination with other agents. The Tourmaline trial showed superior PFS with ixazomib plus lenalidomide and dexamethasone in pts with relapsed or refractory myeloma (RRMM).
Aims: Here, we evaluate the activity and tolerability of ixazomib plus thalidomide and dexamethasone (IxaThalDex) in pts with RRMM.
Methods: Pts with RRMM and one or more prior lines of therapy (TX) with the following criteria were eligible: Measurable disease, ECOG PS ≤2, ANC ≥1000/μL, platelet count ≥50000μL, GFR ≥15mL/min. Treatment regimen: Ixazomib (4mg, d 1, 8 and 15), thalidomide (100mg/d), and dexamethasone (40mg d 1, 8, 15). Pts aged ≥75 years received lower doses of thalidomide (50mg/d) and of dexamethasone (20mg). Pts were scheduled for 8 cycles followed by ixazomib maintenance therapy (4mg, days 1, 8, 15 of a 28 cycle and 3mg in pts aged ≥75 years) for one year. Primary objective was PFS, and secondary objectives were ORR, OS, impact of cytogenetic risk and of renal impairment, safety and health related QoL
Results: Sixty-seven of 77 planned pts have been enrolled so far. The following patient characteristics were recorded in the intent-to treat group (ITT): median age: 67, range 41 to 84 years, ISS stage I: 28, II 22, III: 16, not known: 1, median number of prior TX lines: 1 (range: 1-8). 9 pts discontinued TX before completion of 2 cycles. Presently, 5 pts are too early for evaluation per protocol (PP). Full documentation of ≥2 cycles is available for 52 pts, with a median number of 4 cycles and a median F/U of 7.4 mos. A PR or better was achieved in 33 pts (63%), nCR: 2 pts (4%), VGPR: 10 (19%), PR: 21 (40%), MR: 2 (4%), yielding a clinical benefit rate (CBR) of 67%. FISH data are available in 43 of the 52 PP pts. ≥PR was seen in 11/18 (61%) pts with t (4; 14) and/or t (14; 16) and/or del17p and in 15/25 (60%) with standard risk cytogenetics. Median PFS at the time of reporting is 11.6 mos. in the ITT and 10.4 mos. in the PP group. Median OS has not been reached in neither group. Patients with high-risk cytogenetics did not show statistically significant differences in PFS (10.4 mos. *vs* 10.3 mos., p=0.882) and OS (11.6 mos *vs* median n.r., p=0.061). Global health status/QoL as assessed by EORTC QLQ C-30 instrument revealed clinical meaningful (>5 points) improvement in QoL, which was slightly more pronounced in pts with ≥PR (Figure1). Neutropenia was noted in 19 pts (28%), (15 grade 2 and 4 grade 3). Leucopenia was seen in 19 pts (28%), (14 grade 2 and 5 grade 3). 32 pts (47%) had anemia (23 grade 1/2 and 9 grade 3). Thrombocytopenia was recorded in 11 pts (14%, 4 grade 2 and 6 grade 3). The most frequent non-hematological toxicities were fatigue observed in 21 pts (32%) and infections noted in 27 pts (including 6 pts with pneumonia and 1 pt with sepsis). Polyneuropathy was seen in 19 pts (28%, 18 grade 1 or 2, one grade 3). During the study, the incidence of new PNP was relatively low (17 new and two worsening PNP).

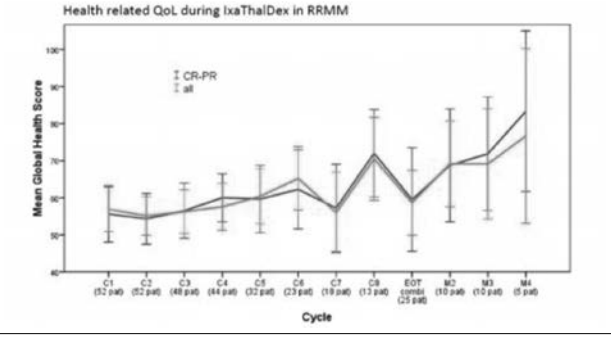

Figure 1.

Summary/Conclusions: The all oral IxaThalDex regimen showed an ORR of 63% with no difference in pts with/without high-risk cytogenetics, a CBR of 67%, and a PFS of 10.4 mos in pts with RRMM. The regimen was well tolerated and was associated with a low incidence of mainly grade ≤2 PNP, which required dose reduction in one patient only. Response rates improved with continuation of therapy and treatment was associated with an increase in health related QoL.

P337

EVALUATION OF GROWTH DIFFERENTIATION FACTOR-1 (GDF15) AS A NEW BIOMARKER FOR RENAL OUTCOMES IN DIFFERENT COHORTS OF PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS

E. Kastritis[1,*], I. Papassotiriou[2], G. Merlini[3], P. Milani[3], E. Terpos[1], M. Basset[3], A. Akalestos[4], F. Russo[3], E. Psimenou[5], F. Apostolakou[2], M. Roussou[1], M. Gavriatopoulou[1], D. Fotiou[1], D.C. Ziogas[1], E. Papadopoulou[1], C. Pamboucas[1], M.A. Dimopoulos[1], G. Palladini[6]

[1]Department of Clinical Therapeutics , National and Kapodistrian University of Athens, [2]Department of Clinical Biochemistry, Aghia Sofia Children's Hospital , Athens, Greece, [3]Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo and University of Pavia, Pavia, Italy, [4]Roche diagnostics, [5]Department of Clinical Therapeutics , National and Kapodistrian University of Athens, Athens, [6]Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo and University of Pavia, Pavia, Greece

Background: Growth differentiation factor-15 (GDF-15), is a member of the TGF-beta family, and is involved in several pathological conditions, including inflammation, cancer, cardiovascular, pulmonary and renal diseases. Serum GDF-15 levels add prognostic information to conventional prognostic factors, such as NT-proBNP and troponins, in cardiovascular disorders and has also shown to be associated with renal damage and risk of end stage renal disease in patients with diabetes. Increased serum GDF-15 levels have also shown to be correlated with early death and shorter survival independently of other cardiobiomarkers and Mayo stage. Because GDF-15 was also associated with renal outcomes we evaluated the prognostic value of GDF-15 levels in two independent cohorts of patients with AL amyloidosis and renal involvement who were treated in two different centers (Pavia Amyloidosis Center and Department of Clinical Therapeutics, Athens).
Aims: To evaluate the prognostic value of GDF-15 levels in independent cohorts of patients with AL amyloidosis and renal involvement .
Methods: Circulating levels of GDF-15 were measured by a novel pre-commercial immunoassay (Roche Diagnostics) in stored serum. The Pavia cohort included 135 and the Athens cohort included 76 patients with AL amyloidosis and renal involvement. Standard criteria were used for the diagnosis, evaluation of organ involvement and cardiobiomarker-based risk stratification. Renal staging was based on the system proposed by Palladini *et al.*, based on baseline proteinuria >5 gr/day and eGFR <50 ml/min.
Results: Median age and involved FLC levels were similar between the two cohorts. However, heart involvement was more common in Pavia cohort (72% *vs* 53% f, p=0.005). Mayo stage disposition was also different (17%, 46% & 37% for stage 1,2 & 3 in Pavia *vs* 30%, 43% & 27% in Athens cohort, p=0.08, but stage 3B was similar, 13% *vs* 12%). Also there were differences in peripheral nerve involvement (9% in Pavia *vs* 21% in Athens cohort, p=0.025). Median eGFR and renal stage distribution (26%, 54%, 20% *vs* 20%, 54%, 26% for renal stage-1, 2 & 3 respectively) were similar between the two cohorts (p=0.544). Median follow up for the Pavia cohort was 18 months and for the Athens cohort was 45 months (p<0.001). Survival at 2 years was 59% for Pavia and 56% for Athens cohort. Median GDF-15 levels was 3454 pg/ml in Pavia (range 624 to >100000) and 4152 pg/ml (range 626 – 71475) in Athens cohort (p=0.09), while 93% and 94% of patients in the two cohorts had GDF-15 levels >1200 pg/ml (the upper limit of normal for individuals without cardiovascular disease). We then evaluated the prognostic significance regarding renal outcomes (dialysis): GDF-15 >4000 pg/ml was associated with a HR of 6 (95% CI 2015.6, p=0.001) in Athens cohort (progression to dialysis within 2 years in 7% *vs* 47%); while, by applying the same cutoff in patients in Pavia cohort, 2-year dialysis rate was 10% *vs* 37% (HR: 3, 95% CI 1.6-15, p=0.004). Although renal stage discriminated 3 groups in univariate analysis in each cohort, in multivariate analysis, GDF-15 >4000 pg/ml outperformed renal stage by eGFR and proteinuria and was the only independent prognostic factor for progression to dialysis in each cohort (Figure 1).

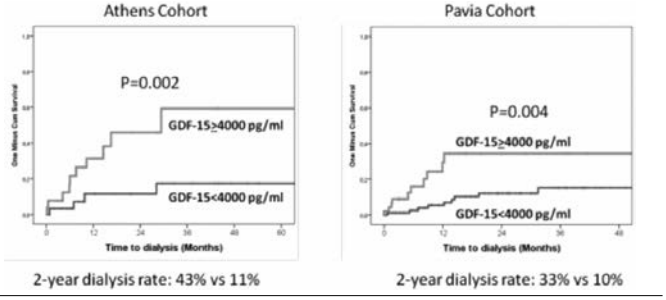

Figure 1.

Summary/Conclusions: Our study validated and confirmed in two independent cohorts, with differences in their characteristics, the prognostic value of GDF-15, which emerges as a novel biomarker with prognostic implications for different outcomes in patients with AL amyloidosis. Importantly, GDF-15 emerges as a strong biomarker for renal outcomes in patients with AL amyloidosis.

P338

AN OPEN-LABEL, PHASE 2 STUDY TO EVALUATE THE ORAL COMBINATION OF IXAZOMIB, CYCLOPHOSPHAMIDE AND DEXAMETHASONE IN TRANSPLANT-INELIGIBLE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

M.A. Dimopoulos[1,*], S. Grosicki[2], W. Jędrzejczak[3], H. Nahi[4], A. Gruber[4], M. Hansson[5], C. Byrne[6], R. Labotka[6], Z. Teng[6], H. Yang[6], N. Grzasko[7], S. Kumar[8]

[1]National and Kapodistrian University of Athens School of Medicine, Athens, Greece, [2]Silesian Medical University, Katowice, [3]Medical University of Warsaw, Warsaw, Poland, [4]Karolinska University Hospital, Stockholm, [5]Skåne University Hospital, Lund, Sweden, [6]Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States, [7]St. John Cancer Center, Medical University of Lublin, Lublin, Poland, [8]Mayo Clinic, Rochester, United States

Background: Proteasome inhibitor (PI)-based combinations are standards of care in all lines of MM therapy. As the treatment paradigm moves to focus more on extended therapy, new combinations are needed that will be efficacious and tolerable, while giving pts the flexibility of taking their treatment at home. Combinations of ixazomib, the first oral PI, with immunomodulatory drugs (IMiDs) are feasible and effective; however, there may be pts for whom the use of IMiDs is not desirable. Therefore, triplet combinations of ixazomib with alkylators have been studied.
Aims: This phase 2 study (NCT02046070) evaluated the safety and efficacy of the all-oral ICd regimen in transplant-ineligible pts with NDMM. Primary endpoint was rate of CR+VGPR during induction. Secondary endpoints included tolerability and toxicity, overall response rate (CR+VGPR+PR) throughout treatment, time to response, PFS, and quality of life (QoL).
Methods: Adult pts with NDMM who were transplant-ineligible were randomized (1:1) to receive oral ixazomib 4.0 mg plus oral cyclophosphamide 300 mg/m^2 (Arm A) or 400 mg/m^2 (Arm B) on days 1, 8, and 15, and dexamethasone 40 mg on days 1, 8, 15, and 22, for up to 13 x 28-day cycles as induction. Pts with ≥SD and an acceptable toxicity profile then received single-agent ixazomib maintenance therapy until PD, death, or unacceptable toxicity.
Results: 70 NDMM pts were enrolled (n=36 Arm A; n=34 Arm B): median age 73 years (range 61–87); 47% male; 31%/33%/29% ISS stage I/II/III MM; 50% had a cardiovascular/pulmonary comorbidity; 9% had high-risk cytogenetics (t(4;14), t(14;16), del 17p). At data cut-off (29 June 2016), pts had received a median of 19 cycles; 66% had completed 13 ICd induction cycles and proceeded to ixazomib maintenance therapy; 10% were ongoing on therapy, and 53% had discontinued due to AEs (24%), PD (16%), patient withdrawal (3%), or other reasons (10%). Confirmed responses by investigator assessment are shown in the Table 1. Median time to first/best response across arms was 2/4 months. After a median follow-up of 17.9/18.5 months in Arm A/B, median PFS was not reached. Combined PFS at 12/18/24 months was 81%/66%/59% (24-month PFS 64%/56% for Arm A/B). In Arm A/B, 94%/100% reported AEs; 72%/74% reported grade ≥3 AEs; and 47%/56% reported SAEs. The most common all-grade AEs were neutropenia (22 [31%]), anemia (19 [27%]), diarrhea, nausea, peripheral edema (each 18 [26%]), vomiting (15 [21%]), fatigue, and constipation (each 14 [20%]). The most common grade ≥3 AEs were neutropenia (22 [31%]), anemia (10 [14%]), lower respiratory tract and lung infections (9 [13%]), and supraventricular arrhythmias (5 [7%]). There were 5 on-study deaths, none considered related to treatment. QoL (by EORTC QLQ-C30; Global Health Status) was maintained from baseline during the study.

Table 1.

Confirmed responses by investigator assessment						
	Arm A (n=33)		Arm B (n=34)		Arm A + Arm B (N=67)	
Response, n (%)	Induction	Overall	Induction	Overall	Induction	Overall
CR	4 (12)	5 (15)	3 (9)	4 (12)	7 (10)	9 (13)
sCR	1 (3)	2 (6)	0	0	1 (1)	2 (3)
PR	22 (67)	22 (67)	21 (62)	20 (59)	43 (64)	42 (63)
VGPR	5 (15)	7 (21)	5 (15)	6 (18)	10 (15)	13 (19)
SD	4 (12)	6 (18)	6 (18)	6 (18)	10 (15)	12 (18)
PD	0	0	1 (3)	2 (6)	1 (1)	0
CR+VGPR	9 (27)	12 (36)	8 (24)	10 (29)	17 (25)	22 (33)
CR+VGPR+PR	26 (79)	27 (82)	24 (71)	24 (71)	50 (75)	51 (76)
CR, complete response; sCR, stringent complete response; PR, partial response; VGPR, very good partial response; SD, stable disease; PD, progressive disease						

Summary/Conclusions: Based on this phase 2 study, ICd is an active treatment regimen for pts with NDMM who are ineligible for transplant. This trial captured a population of pts that was elderly and with multiple comorbidities. In this context, the results with ICd, an all-oral triplet including a PI and alkylator, provide evidence of clinical efficacy with a manageable safety profile. With a median follow-up of ~18 months, median PFS was not reached and outcomes appear comparable to other regimens in elderly transplant-ineligible pts with NDMM. The preferred cyclophosphamide dose for ICd phase 3 studies is 300 mg/m^2, based on the similar PFS, higher response rate, and numerically lower rate of AEs *vs* 400mg/m^2. Updated PFS results will be presented at the meeting.

P339

THE ORAL PROTEASOME INHIBITOR IXAZOMIB IN COMBINATION WITH MELPHALAN-PREDNISONE FOR PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: PHASE 1/2 DOSE-ESCALATION STUDY (NCT01335685)

J. San Miguel[1,*], M.A. Echeveste Gutierrez[2], I. Špicka[3], M.-V. Mateos[4], K. Song[5], M. Craig[6], J. Bladé[7], R. Hájek[8], C. Chen[9], N. Gupta[10], C. Byrne[10], V. Lu[10], H. van de Velde[10], S. Lonial[11]

Background: Bortezomib-MP is a standard-of-care regimen for elderly NDMM pts. Whereas bortezomib is administered IV or SC, ixazomib is an oral proteasome inhibitor with a safety profile amenable to extended dosing that is approved in the US and EU, in combination with lenalidomide-dexamethasone, for the treatment of MM pts who have received at least 1 prior therapy. Based on the demonstrated feasibility and efficacy of a proteasome inhibitor-MP combination, the all-oral ixazomib-MP (IMP) regimen was evaluated in elderly, transplant-ineligible NDMM pts.
Aims: Primary phase 1 objectives were to determine the safety, MTD, and recommended phase 2 dose (RP2D) of ixazomib in combination with MP. The primary phase 2 objective was to determine the rate of CR+VGPR; secondary objectives included PFS and OS.
Methods: In phase 1, pts were enrolled to 4 arms – Arm A: ixazomib 3.0–3.7 mg (days 1, 4, 8, 11, 22, 25, 29, 32) plus M 9 mg/m^2 and P 60 mg/m^2 (days 1–4) in 42-day cycles (max 9 cycles); Arm B: ixazomib 3.0–4.0 mg (days 1, 8, 15) plus M 6 mg/m^2 and P 60 mg/m^2 (days 1–4) in 28-day cycles (max 13 cycles); Arm C/D: ixazomib 3.0–4.0 mg (days 1, 8, 15, 22, 29)/ixazomib 4.0 mg (days 1, 8, 22, 29) plus M 9 mg/m^2 and P 60 mg/m^2 (days 1–4) in 42-day cycles (max 9 cycles). In phase 2, an expansion cohort was enrolled at the RP2D. On all arms, after IMP induction, pts could receive maintenance with single-agent ixazomib (days 1, 8, 15; 28-day cycles).

Table 1.

	All patients	RP2D
Response rates, %	N=53	n=23
Overall response rate (ORR)	66%	65%
At least very good partial response (≥VGPR)	43%	43%
Complete response [CR] (stringent CR)	26% (19%)	22% (17%)
Median time to response, mos		
First response	1.7	1.9
≥VGPR	3.7	3.7
CR	11.6	9.5
Median time to progression (TTP), mos	24.6	18.4
Median progression-free survival (PFS), mos	23.5	18.4
Common AEs, all grades (grade ≥3), %	N=61	n=26
Thrombocytopenia	77% (49%)	62% (27%)
Neutropenia	62% (44%)	46% (23%)
Infections SOC	70% (13%)	69% (12%)
Diarrhea	62% (11%)	65% (15%)
Peripheral neuropathy NEC	39% (5%)	42% (4%)
Peripheral edema	30% (0%)	27% (0%)
Rash NEC	28% (7%)	23% (4%)
AE, adverse event; NEC, not elsewhere classified (high-level term); RP2D, recommended phase 2 dose; SOC, system organ class		

Results: 61 pts were enrolled, 11, 34, 11, and 5 to Arms A, B, C, and D (median age 74 yrs; 31% ISS stage III, 56% creatinine clearance ≤60 mL/min). Among

38 DLT-evaluable pts in phase 1, 10 had DLTs of Gr 3 rash (n=2, Arm A), Gr 3-4 thrombocytopenia (n=4, 1 pt in each arm), Gr 3-4 neutropenia (n=1, Arm A; n=4, Arm C, n=1, Arm D), Gr 4 hemorrhagic oesophageal ulcer (n=1, Arm B), Gr 3 ileus/neurogenic bladder (n=1, Arm B), Gr 3 vomiting/diarrhea (n=1, Arm B), and Gr 3 respiratory infection (n=1, Arm C). The RP2D was ixazomib 4.0 mg in Arm B, based on observed rates of toxicity; this cohort was expanded to 26 pts. Among all 61 pts, the median number of treatment cycles was 16; 36 pts (13 at RP2D) completed IMP induction and entered maintenance. Median number of maintenance cycles was 12. The maximum treatment duration was 1841 days (>5 yrs) at RP2D. Five pts remain on treatment (2 at RP2D); primary reasons for discontinuation were disease progression (48%) and adverse events (AEs, 21%). CR+VGPR rate was 43% (43% at RP2D), including 28% (22%) ≥CR and 19% (17%) sCR; median time to first response was 1.7 mos, and responses continued to mature over a long period (Table 1). Depth of response improved during ixazomib maintenance in 9/36 (25%) pts (VGPR to sCR in 5 pts; VGPR to CR in 2 pts; CR to sCR in 2 pts). Median TTP/PFS are shown in Table 1; median OS was not reached after median follow-up of 42.6/46.9 mos overall/at RP2D.

Summary/Conclusions: The RP2D was weekly ixazomib 4.0 mg plus M 6 mg/m^2 and P 60 mg/m^2 (days 1–4) in 28-day cycles, consistent with the ixazomib dose and schedule in TOURMALINE-MM1. AEs were mainly hematologic, infections, PN, and diarrhea. The all-oral IMP regimen is active in NDMM, with a 28% CR rate (19% sCR), a 43% ≥VGPR rate, and a median PFS of 23.5 mos; responses continued to improve over a prolonged period.

Myeloma and other monoclonal gammopathies - Clinical 2

P340

FEASIBILITY AND EFFICACY OF DOSE ADJUSTED MELPHALAN – PREDNISONE – BORTEZOMIB IN PATIENTS ≥75 YEARS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA; PRELIMINARY RESULTS OF THE PHASE II HOVON 123 STUDY

S. Zweegman[1,*], M.-D. Levin[2], S.K. Klein[3], E.G. de Waal[4], C.M. Eeltink[1], P.F. Ypma[5], A.C. Dijk[6], M. Westerman[7], W. Deenik[8], B. Tanis[9], M.S. Slee-Valentijn[10], M.C. Minnema[11], H. Visser-Wisselaar[12], C. Stege[1], N.W. van de Donk[1], B. van der Holt[12], K. Nasserinejad [12], P. Sonneveld[13]

Background: There is a high rate of toxicity-related discontinuation in elderly patients with NDMM, negatively affecting outcome. In order to predict feasibility of treatment the IMWG developed the frailty score based on age, (instrumental) Activities of Daily Living and the Charlson comordity index.
Methods: Patients were treated with 9 cycles of MPV: Mel 6 mg/m^2, day 1-4; Pred 30 mg/m^2, day 1-4; and Bort 1.3 mg/m^2 day 1,8,15 and 22 of a 35-day cycle. This first planned analysis was restricted to the first 140 consecutive patients out of 240 planned patients.
Results: Of the 139/140 eligible patients none were fit (because of age ≥75 years), 30/139 (22%) were unfit, 100/139 (72%) were frail, and 9/139 (6%) unknown. The median follow up was 17.0 months. The discontinuation rate of MPV in the total population was 42%; 27% in unfit and 46% in frail patients (p=0.09). When also patients were included who discontinued bortezomib only these numbers were 27% in unfit and 52% in frail (p=0.02). Importantly, 6 cycles of MPV were found to be feasible in 70% of patients, both in unfit (80%) and frail (69%) patients. Age >80 years was associated with a significantly higher discontinuation rate of MPV or bortezomib only (70% *versus* 35% in patients aged 75-80 years, p=0.01). WHO performance was not associated with discontinuation rate. Response on protocol was ≥PR 73%, ≥VGPR 38% and ≥CR 11%, not significantly different in unfit *versus* frail patients. Response after 6 cycles was ≥PR 69%, ≥VGPR 35% and ≥CR 2%. Median progression free survival (PFS) was 17 months: 20 for unfit and 16 months for frail patients (p=0.13). Overall survival at 18 months was 76%: 89% for unfit and 72% for frail patients (p=0.22). Frail patients were found to have significantly less grip strength and lower walking speed as compared to unfit patients (Table 1).

Table 1.

	Unfit patients n=30	Frail patients n=100
Median age (range)	77 (75-80)	80 (75-91)
WHO (%)[1]		
0	57	22
1	37	41
2	3	23
3	3	14
ISS (%)[2]		
I	20	12
II	70	32
III	10	51
unknown		5
Grip strength (kg) *		
number of patients	n=29 (1 missing)	n=93 (7 missing)[3]
Low	17%	41%
Intermediate	21%	35%
High	62%	24%
Walking speed (m/s) **		
% of patients	n=29 (1 missing)	N=87 (13 missing)[4]
Low	10%	41%
Intermediate	24%	36%
High	66%	23%

[1] WHO performance significantly less in frail p=0.001 [2] ISS significantly higher in frail p<0.001[3] Grip strength significantly less in frail p=0.001 [4] Walking speed significantly less in frail p<0.001 *Average grip strength of maximum 3 attempts by dominant hand: low indicates ≤ 26.0 kg in men and ≤ 13.3 kg in women; high, ≥ 33.3 kg in men and≥ 21.1 kg in women; and intermediate otherwise, based on tertiles ** Average walking speed of maximum 2 "runs": low indicates ≤ 0.76 m/s in men and ≤ 0.6 m/s in women; high, > 1.0 m/s in men and women; and intermediate otherwise, based on tertiles

However, 58% and 59% of frail patients had an intermediate or high walking speed and grip strength respectively. Vice versa, 8% of patients with low

walking speed and 12% of patients with low grip strength, were not frail but unfit according to the IMWG frailty index. Discontinuation rate in patients with highest and lowest walking speed was 16/41 (39%) and 18/41 (44%). These numbers were 14/42 (33%) *versus* 17/43 (40%) for patients with the highest *versus* the lowest grip strength. PFS was not significantly different between patients with highest *versus* lowest walking speed (p=0.38). However, in contrast to comparable PFS in unfit and frail patients, there was a trend for better PFS in patients with highest *versus* lowest grip strength (20 *versus* 17 months, p=0.05).
Summary/Conclusions: Nine cycles of dose-adjusted MPV results in a high discontinuation rate of 42% in NDMM patients ≥75 years: 27% in unfit *versus* 46% in frail patients. Importantly, 6 cycles of MPV were found to be feasible with comparable response rate, also in frail. Preliminary analyses showed that functional geriatric assessments differed within IMWG frailty groups and that grip strength was associated with PFS, whereas frailty was not. Therefore, functional assesments will hopefully be complementory to the IMWG frailty score in guiding future therapy in unfit and frail patients.

THE EUROPEAN MYELOMA NETWORK EMN09 STUDY: CARFILZOMIB, BENDAMUSTINE, AND DEXAMETHASONE IS EFFICIENT AND SAFE IN PATIENTS WITH ADVANCED MULTIPLE MYELOMA

M. Gramatzki[1,*], A. Günther[1], M. Offidani[2], M. Engelhardt[3], S. Gentili[2], V. Montefusco[4], F. Patriarca[5], E. Angelucci[6], N. Schub[1], M. Astolfi[7], W. Poenisch[8], H. Einsele[9], P. Sonneveld[10], P. Corradini[4], A. Palumbo[11], F. Gay[7]

Background: Even after a prolonged treatment patients with multiple myeloma may have received little chemotherapy, however many may suffer from bortezomib induced peripheral neuropathy (PN). Bendamustine (Benda) leads to increased levels of defective ribosomale products (DRiPs). Carfilzomib (Carf), a proteasome inhibitor not inducing PN, inhibits degradation of DRiPs leading to plasma cell apoptosis.
Aims: With this scientific rationale a CBd combination of Carf and Benda and low dose dexamethasone (dex) was evaluated in a phase 1/2 trial in patients with relapsed/refractory multiple myeloma (RRMM).
Methods: Sixty-three patients with RRMM with ≥2 lines of prior therapy were enrolled with the last patient included in February 2017. Treatment consisted of 28-day cycles of Benda 70 mg/m^2 on day 1 and 8, Carf was given on day 1, 2, 8, 9, 15, 16 at 27 mg/m^2 after an initial dose of 20 mg/m^2. In 6 patients in the phase 1 part of the trial Carf was escalated to 36 mg/m^2. This was found to be the MTD. 20 mg dex was added on every treatment day and day 22 and 23. After 8 cycles, responding patients received maintenance only every 14 days with Carf for two days plus dex until progression.
Results: The phase 1 part of the trial suggested Carf at the 27 mg/m^2 level for the phase 2 part. Forty-one patients were evaluated for response and efficacy. At last data cut-off, the median follow-up was 5.95 months. Number of prior treatment lines ranged from 2 to 9, and ≥85% of patients had received previously transplantation, bortezomib and immunomodulatory drugs. The median time elapsed from diagnosis to treatment start was 5.8 years. Forty-three percent of patients achieved at least a PR including 28% ≥VGPR and an overall benefit of 92%. Median progression-free survival was 11.4 months and the 1-year overall survival was 75%. Hematological toxicity was well manageable. Non-hematological adverse events ≥grade 3 were infections, followed by dyspnea, cardiac events and thromboembolism. These data will be up-dated before the meeting.
Summary/Conclusions: In this elderly RRMM patients treated late in their disease, the combination of CBd provides effective outpatient therapy. Neither nausea, hair loss nor PN were an issue. Although cardiopulmonary as well as vascular signs need attention, CBd appears a very tolerable treatment option. In this heavily immunosuppressed patient population infection prophylaxis is mandatory.
Clinical trial information: NCT02056756.

P342

CHEMOTHERAPY BEFORE AND AFTER HEART TRANSPLANTATION FOR PATIENTS WITH ADVANCED CARDIAC AL AMYLOIDOSIS, SINGLE CENTER RESULTS WITH LONG-TERM FOLLOW-UP

U. Hegenbart[1,*], K. Haack[1], A. Kristen[2], P. Blum[2], C. Kimmich[1], H. Katus[2], A. D. Ho[3], A. Ruhparwar[4], P. Raake[2], S. Schönland[1]
[1]Amyloidosis Center, [2]Div. of Cardiology, [3]University Hospital, Heidelberg, Germany, [4]Cardiac Surgery, University Hospital, Heidelberg, Germany

Background: Survival rates for patients with light-chain (AL) amyloidosis are gravely reduced by advanced cardiac involvement at Mayo cardiac stage IV with a median survival of 6,5 months. High-dose Melphalan (HDM) and autologous stem cell transplantation (ASCT) or other intense chemotherapy regimen cannot be applied to those patients due to the high risk of therapy-related mortality. One approach to improve the catastrophic prognosis of those patients is to perform a heart transplantation followed by intense chemotherapy.
Aims: Our aim was to examine the cases of cardiac AL patients treated with heart transplantation (HTx) at our center and to evaluate the clinical outcome of this treatment approach.
Methods: Data from 41 patients (21m, 20f) suffering from cardiac AL who were treated in our hospital between 2002 and 2017 were retrospectively analyzed. All patients were high-urgency listed for orthotopic HTx due to poor perspective of survival. Until 2009, 13 patients were listed, 8 of them with multiple organ involvement. Thereafter, we excluded patients with multiple organ involvement. All data are derived as medians with range or absolute numbers. Survival curves were calculated using the Kaplan-Meier method.
Results: Median age was 51 years (35-63) at diagnosis. Amyloidogenic lambda light-chains (LC) were detected in 35 and kappa LC in 6 patients. Median dFLC was 331 (69 – 2752) and median plasma cells in bone marrow were 13% (5-35). Median NT-proBNP was 6.332 ng/l (1.500 -53.194), median cTNT 0,11 µg/l (0,01-0,52) and median hsTNT was 60 ng/l (28-448) at diagnosis. Median NYHA stage was 3 (2-3) and median MAYO 2004 stage was 3 (2-3). Serum creatinine was at a median of 0,94 mg/dl (0,66-2,45), proteinuria at 0,1 g/day (range 0-10,7). Patients stayed on the high-urgency waiting list for a median of 26 (range 3-54) before 2009, and a median of 64 days (8-259) after 2009. 35 patients were treated with chemotherapy prior to HTx (mostly dexa w/o Bortezomib) to reduce dFLC during the waiting time. Eight patients died before receiving HTx with a median survival (start point: HU listing) of 26 days (6-177). With a median of 5 months after HTx (4-29), 18 patients received ASCT. HDM was used with either 200 mg/m2 (N=10) or reduced dosage (N=8) in patients with reduced kidney function (mostly due to renal complications after HTx). Complete remission (CR) was achieved in 7 patients (24% of all transplanted pts, n=29; 2 patients have not finished treatment yet), very good partial remission (VGPR) in 6 patients (21%) and partial remission (PR) in 7 patients (24%). Overall, 25 patients died. Cause of death was either progression of AL (N=16), sepsis (n=4), heart transplant rejection (n=3) or other (n=2). Patients that underwent HTx had a median survival of 46 months (2-177, 1-year survival: 77%).
Summary/Conclusions: HTx followed by chemotherapy is a feasible treatment approach in patients with advanced cardiac amyloidosis. Patients who reach HTx have a nearly 50% chance for a very good hematologic remission (VGPR or better) and consecutively a favorable survival probability with a median OS of nearly 6 years in our series.

P343

MM-013 PHASE 2 MULTICENTER STUDY OF POMALIDOMIDE PLUS LOW-DOSE DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA AND RENAL IMPAIRMENT

P. Sonneveld[1,*], K. Weisel[2], N. van de Donk[3], K. Ramasamy[4], B. Gamberi[5], M. Streetly[6], M. Offidani[7], F. Bridoux[8], J. de la Rubia[9], E. Kueenburg[10], S. Collins[10], A. Di Micco[10], B. Rosettani[10], P. Bacon[10], M. Dimopoulos[11]
[1]Erasmus MC Cancer Institute, Rotterdam, Netherlands, [2]University Hospital of Tuebingen, Tuebingen, Germany, [3]VU University Medical Center, Amsterdam, Netherlands, [4]Oxford University Hospital, Oxford, United Kingdom, [5]Arcispedale S. Maria Nuova, Reggio Emilia, Italy, [6]Guy's Hospital, Guy's and St Thomas' NHS Trust, London, United Kingdom, [7]Clinica di Ematologia, AOU Ospedali Riuniti di Ancona, Ancona, Italy, [8]University Hospital and University of Poitiers, Poitiers, France, [9]Hospital Dr. Peset, Valencia, Spain, [10]Celgene International, Boudry, Switzerland, [11]National and Kapodistrian University of Athens, Athens, Greece

Background: RI is a common comorbidity in pts with multiple myeloma (MM) that increases in incidence as the disease progresses and is associated with poor prognosis. Approximately 20% to 30% of pts with MM have RI at time of diagnosis; ≈ 2% to 13% of whom will require dialysis. The immunomodulatory agent, POM, in combination with LoDEX demonstrated comparable efficacy and tolerability in pivotal RRMM trials in pts with moderate RI. However, this regimen had not previously been fully studied in pts with severe RI or pts requiring hemodialysis.
Aims: To present updated safety and efficacy analyses from the multicenter, phase 2 MM-013 trial, in which pts with RRMM and moderate or severe RI, including those on hemodialysis, were treated with POM+LoDEX.
Methods: Three cohorts of pts with RRMM and RI were enrolled: (A) – moderate RI (estimated glomerular filtration rate [eGFR] ≥30 to <45 mL/min/1.73m^2), (B) – severe RI (eGFR <30 mL/min/1.73m^2) without hemodialysis, and (C) – severe RI requiring hemodialysis. All pts must have received ≥1 prior treatment including LEN and progressed during or after their last anti-myeloma treatment before entering the study. Pts received POM+LoDEX until disease progression

or unacceptable toxicity. Supportive care was allowed; thromboprophylaxis was required for all pts not on hemodialysis. The primary endpoint was overall response rate (ORR). Key secondary endpoints included safety, renal response, time to myeloma response, time to renal response, duration of response, progression-free survival (PFS), time to progression, and overall survival (OS). All pts provided informed consent.

Results: Enrollment has been completed with 81 pts (33 in cohort A; 34 in cohort B; 14 in cohort C), of which 13 (16.0%) were still on treatment as of January 28, 2017. Median follow-up for OS was 7.8 months. A total of 68 pts (84.0%) discontinued treatment; 39 (48.1%) due to PD. Median age was 72 yrs (range, 52-86 yrs), 60.5% of pts were male, and median time from diagnosis was 3.8 yrs (range, 0.03-19.44 yrs). Pts received a median of 4 (range, 1-10) prior anti-myeloma therapies. All pts had prior treatment with LEN (100%) and nearly all with BORT (97.5%). Median relative dose intensity of POM was 0.94 in both cohorts A and B, and 0.99 in cohort C. ORR was 39.4%, 29.4%, and 14.3% in cohorts A, B, and C respectively. PFS and OS results are presented in the Table 1. Grade 3/4 anemia and thrombocytopenia occurred more frequently in cohort C, likely due to severe RI requiring dialysis (Table 1). AEs leading to dose reductions were 18.2%, 14.7%, and 14.3% in cohorts A, B, and C, respectively.

Table 1.

	Cohort A (n = 33)	Cohort B (n = 34)	Cohort C (n = 14)
Grade 3/4 TEAEs, n (%)			
Hematologic			
Neutropenia	20 (60.6)	15 (44.1)	8 (57.1)
Anemia	9 (27.3)	12 (35.3)	8 (57.1)
Thrombocytopenia	9 (27.3)	6 (17.6)	6 (42.9)
Febrile neutropenia	1 (3.0)	1 (2.9)	0
Non-hematologic			
Infections	12 (36.4)	9 (26.5)	4 (28.6)
Pneumonia	4 (12.1)	2 (5.9)	1 (7.1)
Efficacy			
ORR (≥ PR), n (%)	13 (39.4)	10 (29.4)	2 (14.3)
CBR (≥ MR), n (%)	16 (48.5)	13 (38.2)	3 (21.4)
PFS, median (95% CI), mos	6.5 (4.6, 10.6)	4.2 (2.8, 6.5)	2.4 (1.0, 6.4)
OS, median (95% CI), mos	17.7 (7.8, NE)	11.8 (6.4, 14.3)	5.2 (1.8, 9.7)
Renal response, n (%)	7 (21.2)	12 (35.3)	1 (7.1)

CBR, clinical benefit rate; MR, minimal response; NE, not estimable; PR, partial response; TEAE, treatment-emergent adverse event.

Summary/Conclusions: POM+LoDEX is efficacious in pts with RRMM with moderate or severe RI, including those on hemodialysis, who had more advanced disease due to worse renal function. The safety profile was acceptable among the three groups and no new safety signals were observed. This study demonstrates that POM+LoDEX can be administered in pts with moderate or severe RI, including those on hemodialysis.

P344

PEMBROLIZUMAB MONOTHERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA: PHASE 1B KEYNOTE-013 STUDY

V. Ribrag[1,*], D.E. Avigan[2], G. Martinelli[3], D.J. Green[4], T. Wise-Draper[5], J.G. Posada[6], R. Vij[7], Y. Zhu[8], M.Z. H. Farooqui[8], P. Marinello[8], D.S. Siegel[9]
[1]Institut Gustave Roussy, Villejuif, France, [2]Beth Israel Deaconess Medical Center/ Harvard Medical School, Boston, United States, [3]Institute of Hematology "L. e A. Seràgnoli," University of Bologna, Bologna, Italy, [4]University of Washington, Seattle, [5]University of Cincinnati Cancer Institute, Cincinnati, [6]Central Texas Veterans Affairs Health Care System, Temple, [7]Washington University School of Medicine, St. Louis, [8]Merck and Co., Inc., Kenilworth, [9]Hackensack University Medical Center, Hackensack, United States

Background: Treatment options are needed for patients with RRMM. PD-L1 is expressed in patients with multiple myeloma, and blocking the programmed death 1 (PD-1) pathway may provide antitumor activity. Pembrolizumab is a humanized, high-affinity monoclonal antibody directed against PD-1 with robust antitumor activity and favorable safety in several solid and hematologic malignancies. KEYNOTE-013 (NCT01953692) is a multicohort phase 1b study of pembrolizumab monotherapy in patients with hematologic malignancies; results are reported for patients with RRMM.

Aims: To determine the safety, tolerability, and antitumor activity of pembrolizumab monotherapy in patients with RRMM.

Methods: Patients with RRMM who have failed ≥2 prior lines of therapy including a proteasome inhibitor and immunomodulatory drug (IMiD) received pembrolizumab 10 mg/kg every 2 weeks or 200 mg fixed dose every 3 weeks. Primary end points were safety, tolerability, and objective response rate (ORR) as determined by investigators, per International Myeloma Working Group 2006 criteria.

Results: At data cutoff of January 2, 2017, 30 patients were treated. The median (range) duration of follow-up was 15 (1-32) months. 28 (93%) patients discontinued the study; the most common reason was disease progression in 14 (47%) patients and clinical progression in 9 (30%) patients. 2 (7%) patients are still on treatment. Median (range) age was 70 (56-81) years. 21 (70%) patients had an ECOG performance status of 1. Patients received a median (range) of 4 (2-10) prior lines of therapy. 20 (67%) patients were lenalidomide refractory, 10 (33%) were double-refractory, 9 (30%) were triple refractory, and 1 (3%) patient was quadruple refractory. Among patients who received pembrolizumab at 10 mg/kg, the median (range) of pembrolizumab exposure was 6 (2-15) cycles; among those who received 200-mg fixed dose of pembrolizumab, the exposure was 3 (2-6) cycles. No patient experienced a response. Seventeen (57%; 95% CI, 37-75%) patients had stable disease. 13 (43%; 95% CI, 26-63%) patients had progressive disease as their best response. Treatment-related adverse events (TRAEs) occurred in 12 (40%) patients. The most common TRAE was asthenia (n=5, 17%); arthralgia, aspartate aminotransferase increased, fatigue, hyperglycemia, hypothyroidism, myalgia, pruritus, and blurred vision occurred in 1 patient each. A grade 3 TRAE (myalgia) occurred in 1 (3%) patient. There were no grade 4 TRAEs and no deaths due to TRAEs. 1 (3%) patient had an immune-related adverse event (grade 1 pruritus).

Summary/Conclusions: The safety profile of pembrolizumab in RRMM was consistent with that observed with other cancers. Best response observed while on pembrolizumab monotherapy was stable disease. Recent results of ongoing studies, such as KEYNOTE-023 (NCT02036502), demonstrate promising efficacy of pembrolizumab in combination with IMiDs (lenalidomide) and dexamethasone in patients with RRMM.

P345

ASSESSMENT OF MOBILIZATION COST FOR MULTIPLE MYELOMA USING 2 DIFFERENT STRATEGIES: HIGH-DOSE CYCLOPHOSPHAMIDE VERSUS PLERIXAFOR. ON BEHALF OF IFM

Z. Van De Wyngaert[1,*], V. Nerich[2], M.-L. Chrétien[3], N. Azar[4], P. Lenain[5], M. Macro[6], J.-H. Bourhis[7], L. Garderet[8], M. Mohty[8], A. Jaccard[9], L. Karlin[10], C. Giraud[11], S. Guidez[12], B. Hebraud[13], M. Roussel[13], G. Marit[14], C. Hulin[14], E. Deconinck[15], M. Attal[13], P. Moreau[16], S. Limat[2], X. Leleu[12], D. Caillot[3]

Background: Treatment with autologous transplantation (ASCT) remains the standard of care upfront for Multiple Myeloma patients considered eligible for transplant. Peripheral blood stem cell (PBSC) collection, also called mobilisation, is needed prior to ASCT. The optimal methodology for mobilizing PBSC has yet to be defined, with either G-CSF alone, also called steady state procedure, or use of Plerixafor, a CXCR4 antagonist (Mozobil®)+G-CSF or high dose cyclophosphamide (usually administered at a dose of 1.5 to 6g/m^2 IV for one to two days)+G-CSF. The former is rarely used with the most recent induction regimens, and the 2 latter have demonstrated similar PBSC collection rates. Because of the intense competition for hospital resources and the staff required to manage patients preparing for mobilization and transplantation, it is important to quantify the total impact of mobilization on staff resource and cost to the hospital.

Aims: We aimed at better evaluate the respective cost of the 2 techniques of mobilization for the French health care system, high dose cyclophosphamide (n=57) *versus* plerixafor (n=55).

Methods: This is an observational cohort database analysis of 112 consecutive patients with MM treated upfront with ASCT between 2009 and 2013 and that had been mobilized with either high dose cyclophosphamide or plerixafor from 15 IFM centers. Patients must have successfully underwent ASCT. This study was not aimed at evaluating the suitability or advisability of one therapy *versus* another. A cost-consequences analysis of the different regimens of mobilization will be performed. Cost will be quantified using "microcosting" approach. Only direct medical costs are included in this economic analysis. Hospital resources will be calculated using two different approaches: per diem hospitalization costs (excluding direct medical costs) *versus* French public diagnosis-related group

(DRG). The point of view of the French Public Health System is adopted for this study. Monetary values for 2012 euros prices will be used for all components.
Results: Median (range) age was 59.5 (24-72), sex ratio was 1.5, ISS 3 was 26% in either group, all patients were collected to allow the number of graft requested by the hematologist of reference. The median CD34 collected was 8.9 (4-30) for HD cyclophosphamide and 5.8 (2-15) for plerixafor. The analysis demonstrated that days in the hospital were the primary cause for cost difference across the 2 mobilization techniques. In that regards, plerixafor appeared very cost effective compared to HD cyclophosphamide. All data will be updated at EHA 2017 including cost comparison.
Summary/Conclusions: For a long time HD cyclophosphamide was recommended for mobilization upfront in Myeloma therapy, as it was needed to improve response rate and depth of response, despite only 10% of the patients improving. With the progress made recently with the induction regimens, the choice for the mobilization regimen is now based more on safety and cost saving. In that regards, one must acknowledge that plerixafor has become one, if not the, most attractive option for Myeloma.

P346

SYSTEMATIC LITERATURE REVIEW AND NETWORK META-ANALYSIS OF INDUCTION TREATMENT FOR NEWLY DIAGNOSED TRANSPLANT-ELIGIBLE MULTIPLE MYELOMA PATIENTS

J.-C. Kim[1,*], J.H. Lim[1], M.H. Lee[1], H.G. Yi[1]
[1]hemato-oncology, Inha University Hospital, Incheon, Korea, Republic Of

Background: Based on the current guideline, bortezomib-based two or three drug regimens are mainly listed as a category 1 primary treatment option for transplant-eligible patients with myeloma. However, to date there are few direct head-to-head randomized controlled trials (RCTs) comparing effects of these recommended regimens, which makes it difficult to assess which treatment is most favorable to obtaining high response rates.
Aims: to determine the ranking of the currently recommended induction regimens and to compare efficacy of all available treatments.
Methods: We conducted a systematic literature review to identify all eligible RCTs that include at least one currently recommended regimen by searching PubMed, Web of Science, ASH, ASCO, EHA, and ESMO databases. A Bayesian network meta-analysis (NMA) with a fixed-effect model was performed to rank the regimens of their very good partial response rates or better (≥VGPR) and provide a comparison of treatment options. One of the most commonly utilized regimens, lenalidomide-dexamethasone, was used as reference treatment.
Results: Ten RCTs were identified including nine treatment regimens : vincristine-doxorubicin-dexamethasone (VAD), thalidomide-dexamethasone (TD), bortezomib-dexamethasone (VD), bortezomib-doxorubicin-dexamethasone (PAD), bortezomib-cyclophosphamide-dexamethasone (VCD), bortezomib-thalidomide-dexamethasone (VTD), bortezomib-thalidomide-dexamethasone-cyclophosphamide (VTDC), lenalidomide- dexamethasone (RD) and bortezomib-lenalidomide-dexamethasone (VRD). Figure 1 shows the probability of being the best induction treatment. The Figure 1 also presents the postinduction odds ratios for achieving a ≥VGPR and 95% credible intervals (CrI) *versus* RD. This analysis showed a significantly higher ≥VGPR with VRD compared with most of the other investigated interventions, including VD, PAD, VCD and RD (OR [95% CrI]): VD 4.4 [1.2–19.6]; PAD 3.8 [1.1–16.2]; VCD 3.4 [1.1–14.2]; RD 1.7 [1.1–2.5]. The similar result was also seen in comparing with VTD and VTDC, but the difference did not reached statistically significant level : VTD 2.4 [0.7–10.4]; VTDC 2.4 [0.5-13.7]. VRD was identified as the best induction treatment since it was the most favorable in terms of i) only treatment that was significantly better than RD, and ii) probability of being best regimen (84% of the simulations).

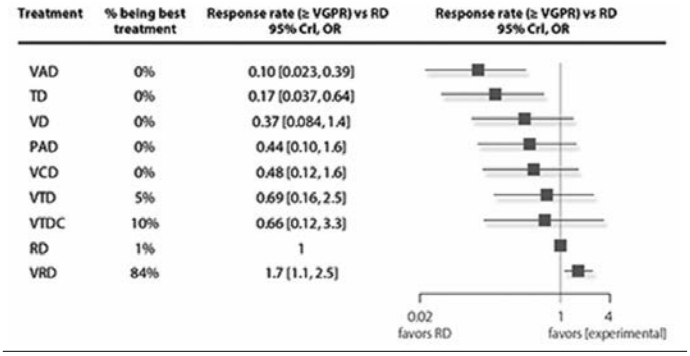

Figure 1.

Summary/Conclusions: Our systematic review and NMA included most of the recommended induction treatments for transplant-eligible myeloma patients and identified VRD as being most effective in achievement of ≥VGPR. NMAs can provide an overview of the best treatment and each regimen's relative efficacy in case of lacking head-to-head RCTs, thereby supporting clinical decision-making.

P347

A STUDY OF UTILITY OR FUTILITY OF PERFORMING SKELETAL SURVEYS IN PARAPROTEINAEMIA: A MULTICENTER EXPERIENCE FROM UK

O. Gamage[1,*], M. Zaw[1], S. Gurung[1], G. Pratt[2], S. Shafeek[3], A. Macwhannell[1], S. Lee[1], S. Basu[1]
[1]Department of clinical Haematology, Royal Wolverhampton NHS Trust, Wolverhampton, [2]Department of Haematology, University Hospital, Birmingham, UK, Birmingham, [3]Department of Haematology, Worcestershire Acute Hospital Trust, Worcester, United Kingdom

Background: Recent International Myeloma Working Group(IMWG) guidelines recommend that conventional skeletal surveys should be supplanted by low dose whole body computed tomography (CT),whole body magnetic resonance imaging (MRI) and or ^{18}fluoro-deoxyglucose (^{18}F-FDG/PET)[1] .However, resource, funding and radiology capacity issues, have posed significant challenges to implementing these recommendations. The risk of progression of Monoclonal Gammopathy of Undetermined Significance (MGUS) to a neoplastic plasma cell disorder is approximately 1% per year[2] and even lower in low risk MGUS. It is thus not necessary to perform imaging in unselected MGUS patients.
Aims: To look at all skeletal surveys requested across 3 large hospitals in UK over a year and analyze their justification, effectiveness and utility.
To decide if a rational clinico–biochemical algorithm could be used to reduce the number of imaging requests, thereby avoiding unnecessary radiation exposure, and make a possible switch to modern imaging methods cost effective
Methods: A total of 397 skeletal surveys were performed across three hospitals over one year. The data set was analyzed for clinical indications, paraprotein level, rationale for requesting the skeletal survey, the diagnostic yield and also the number of follow up CT/ PET or MRI required.
A pragmatic algorithm was developed and applied to see if the requests were justified and could have been safely reduced. (Figure1).
Results: Of the 397 analyzable skeletal surveys performed, 266 were on myeloma, 81 for MUGS, 48 were for non-paraprotein related indications. Of the 266 myelomas, 30% of skeletal surveys were reported as positive according to IMWG criteria[1]. A detailed analysis of 130 myeloma patients revealed a significant proportion of false negatives (6%) and false positives (7%), highlighting the insensitivity and poor specificity of this imaging modality. More importantly more than a third (38%) of myeloma patients required follow up imaging with MRI, PET or WBLDCT irrespective of the initial skeletal survey result, indicating a significant duplication rate and waste of resources. In the MGUS group, majority of skeletal surveys were negative (91%) but 9% were reported as positive. Follow up imaging with CT and MRI was performed in 23% of the MGUS group. However none these were positive. When the clinico-biochemical algorithm was applied, the number of requests was reduced by at least a quarter (24%), avoiding unnecessary radiation exposure and precious resources.

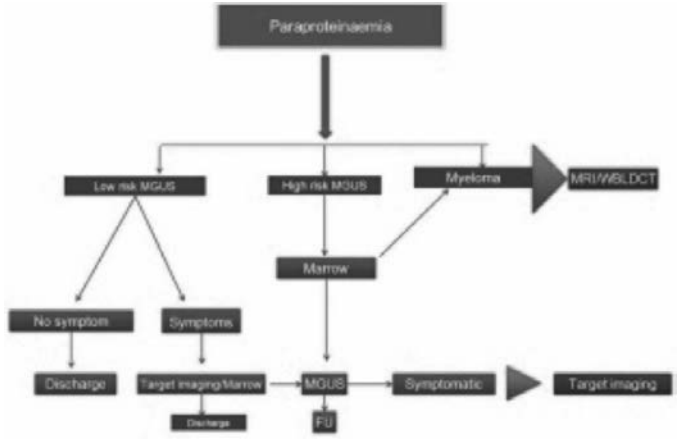

Figure 1.

Summary/Conclusions: - Skeletal survey has very limited role in investigation of paraproteinaemia and should be abandoned. - Our pragmatic clinic-biochemical imaging algorithm reduced imaging requests significantly(24%) allowing the preferred imaging modalities to be performed productively in a cost effective way in face of ever increasing health care cost and demands.

P348

SERUM FLC MEASUREMENTS COMPLEMENT BONE MARROW ASSESSMENT TO DETERMINE PROGNOSIS IN MYELOMA PATIENTS ACHIEVING DEEP RESPONSES

T. Dejoie[1,*], M. Attal[2], P. Moreau[3], H. Avet-Loiseau[4]
[1]Biochemistry Laboratory, Centre Hospitalier Universitaire-Nantes, Nantes, [2]Institut Universitaire du Cancer-Oncopole, Toulouse, [3]Department of Hema-

tology, Centre Hospitalier Universitaire-Nantes, Nantes, [4]Unite de Genomique du Myelome, Institut Universitaire du Cancer-Oncopole, Toulouse, France

Background: In multiple myeloma (MM), abnormal serum free light chain ratios (FLCr) after therapy associate with poor prognosis, independent of depth of response. However the value of FLCr in the context of minimal residual disease (MRD) remains unclear. A proportion of MRD-negative patients experience early relapses and conversely, some MRD-positive patients can endure long-term survival; which may result from improved immunosurveillance following normal plasma-cell recovery.
Aims: We hypothesised that serum FLC levels and ratios add clinical value at the time of MRD assessment.
Methods: The study included 275 intact immunoglobulin MM patients from the IFM2009 clinical trial who achieved at least a very good partial response (VGPR) after consolidation therapy. Median PFS from the end of consolidation was 38.3 months; median OS was not reached. Serum FLCs were measured using Freelite immunoassays (The Binding Site). Normal range for k/l FLCr was 0.26-1.25. We defined immunosuppression as levels of both the uninvolved (polyclonal) FLC+uninvolved heavy+light chain (HLC; measured with Hevylite) below their normal range. MRD assessment in bone marrow samples was based on 4-colour multiparametric flow cytometry (MFC).
Results: At the end of consolidation, 79/275 (29%) patients were MRD-positive, 79/275 (29%) had abnormal FLCr, 16/275 (6%) had elevated iFLC, with immunosuppression identified in 52/275 (19%). Using Cox regression all the variables associated with shorter PFS (p<0.001 for all) and OS (p<0.050 for all; except elevated iFLC which showed a trend towards shorter OS (p=0.070)). Among 196 MRD-negative patients, 37/196 (19%) had abnormal FLCr, 2/196 (1%) had elevated iFLC with immunosuppression identified in 23/196 (12%). Median PFS for MRD-negative patients was not reached; however both an abnormal FLCr (median PFS: 31.4 months; p<0.001) and immunosuppression (median PFS: 31.4 months; p=0.005) identified a group of patients with poorer outcomes. On the other hand, median PFS for MRD-positive patients was 21.3 months; 42(53%) of these patients had abnormal FLCr and dismal outcomes (median PFS 12.6 *vs* 30.7 months for abnormal *vs* normal FLCr, respectively; p=0.004). Absolute FLC measurements did not reach statistical significance for PFS in these patients.
Summary/Conclusions: Serum FLC measurements in combination with low-sensitivity MFC bone marrow assessment at the end of consolidation therapy render the most powerful prognostic information in MM patients achieving deep responses. In those where disease is no longer detected using MFC, abnormal FLCr confer poor prognosis, which may partly be due to inefficient immune recovery. Absolute FLC measurements were not informative, supporting the rationale of evaluating biomarkers of the tumour and immune system recovery. Our results warrant further studies to validate the clinical utility of FLC measurements in combination with next-generation (8-colours) flow cytometry.

P349

THE CONNECT MM REGISTRY: IMPACT OF THE CYTOGENETIC ABNORMALITY T(11;14) ON SURVIVAL OUTCOMES IN AFRICAN AMERICAN AND NON-AFRICAN AMERICAN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

C.J. Gasparetto[1,*], R. Abonour[2], S. Jagannath[3], B.G. Durie[4], J.J. Shah[5], M. Narang[6], H.R. Terebelo[7], K. Toomey[8], J.W. Hardin[9], L. Wagner [10], S. Srinivasan[11], A. Kitali[11], E.D. Flick[11], F. Zafar[11], A. Agarwal[11], R.M. Rifkin[12]
[1]Duke University Medical Center, Durham, [2]Indiana University Simon Cancer Center, Indianapolis, [3]Mount Sinai Hospital, New York, [4]Cedars-Sinai Samuel Oschin Cancer Center, Los Angeles , [5]MD Anderson Cancer Center, Houston, [6]US Oncology Research, Maryland Oncology Hematology, Columbia, [7]Providence Cancer Institute, Southfield, [8]Steeplechase Cancer Center, Somerville, [9]University of South Carolina, Columbia, [10]Wake Forest University School of Medicine, Winston-Salem, [11]Celgene Corporation, Summit, [12]US Oncology Research, Rocky Mountain Cancer Centers, Denver, United States

Background: The cytogenetic abnormality t(11;14) is common, occurring in approximately 20% of patients with newly diagnosed multiple myeloma (NDMM) (Avet-Loiseau, *Leukemia*, 2013). Historically, t(11;14) has been associated with standard-risk multiple myeloma (MM) and generally favorable outcomes (Avet-Loiseau, *Leukemia*, 2013). However, some retrospective analyses have reported the presence of t(11;14) to be a poor prognostic factor (Kaufman, *Leukemia*, 2016). Connect MM is a largely community-based, US prospective observational cohort study that collects data on management and natural history of patients with NDMM in clinical practice.
Aims: This analysis assessed the impact of t(11;14) on survival outcomes in African American and non-African American patients in a mostly community-based setting.
Methods: Adult patients with NDMM within 60 days of diagnosis were eligible for enrollment in the registry. Patients who completed induction and were tested for t(11;14) by fluorescence *in situ* hybridization or cytogenetics were grouped by race (African American and non-African American). Endpoints were progression-free survival (PFS) and overall survival (OS). Kaplan-Meier analyses were adjusted for cohort, age, International Staging System stage, transplant intent, presence of t(4;14), diabetes history, and baseline levels of hemoglobin, platelets, calcium, and creatinine. Data cutoff was Jul 7, 2016.
Results: 3011 patients were enrolled in 2 cohorts. Cohort 1 enrolled 1493 patients from Sep 2009–Dec 2011; median follow-up was 39.3 months. Cohort 2 enrolled 1518 patients from Dec 2012–Apr 2016; median follow-up was 16.4 months. A total of 1539 (52%) patients were tested for t(11;14). Of these, 363 (24%) were positive for t(11;14). By race, 53 (26%) of 205 African American and 310 (23%) of 1334 non-African American patients were positive for t(11;14). First-line bortezomib exposure was similar across all groups. In African American patients, the presence of t(11;14) resulted in a trend toward shorter PFS compared to those without t(11;14) (Table 1. Additionally, African American patients with t(11;14) had significantly higher risk of death compared to African American patients without t(11;14). A higher rate of early mortality was observed *vs* non-African American patients. In non-African American patients, no differences in PFS or OS were noted based on the presence or absence of t(11;14). For OS, the interaction between race and t(11;14) status was statistically significant (*P*=0.004).

Table 1.

	African American (n=205)			Non-African American (n=1334)		
	t(11;14)			t(11;14)		
	Yes (n = 53)	No (n = 152)	Adjusted Hazard Ratio (95% CI)	Yes (n = 310)	No (n = 1024)	Adjusted Hazard Ratio (95% CI)
Median PFS, months	19.1	45.2	0.66 (0.41, 1.04) *P* = .076	33.1	38.1	1.03 (0.84, 1.25) *P* = NS
Median OS, months	not reached	not reached	0.44 (0.23, 0.84) *P* = .012	69.3	71.0	1.17 (0.90, 1.54) *P* = NS

NS, not significant.

Summary/Conclusions: In Connect MM, the effect of t(11;14) on OS was significantly different between African American and non-African American patients. Specifically, t(11;14) was associated with poorer survival outcomes in African American patients, and not in non-African American patients. Thus, the presence of t(11;14) may be a risk factor for poor prognosis in African American patients. Additional analyses will be conducted to elucidate the role of induction treatment, transplant and maintenance in African American and non-African American patients with t(11;14).

Background: Juvenile myelomonocytic leukemia (JMML) is an aggressive myeloproliferative disorder of early childhood. While some cases show spontaneous remission, allogeneic hematopoietic stem cell transplantation (HSCT) remains the only curative treatment option for the majority of patients, however, the 5-year event-free survival reaches only about 50%. Hyperactive RAS signaling is assumed to be the main driving event in JMML. It is caused by genetic alterations in *CBL*, *KRAS*, *NF1*, *NRAS,* or *PTPN11* in about 90% of patients. So far, there is no clear understanding of how RAS pathway mutations relate to the heterogeneous disease biology and variable clinical outcome seen in JMML patients. As a consequence, established clinical and genetic markers fail to fully represent the observed disease heterogeneity.
Aims: We hypothesized that DNA methylation profiling, either alone or in combination with genetic alterations, might provide a molecular basis for disease classification.
Methods: Genome wide DNA methylation analysis using the HumanMethylation450 Bead Chip array was performed in a discovery cohort of 20 JMML patients. We developed a strategy to eliminate methylation events that attribute to epigenetic changes in normal hematopoiesis. The clinical relevance of our findings was assessed in an unselected sample set consisting of 148 consecutive patients with JMML (n=130) or Noonan syndrome associated myeloproliferative disorder (n=18) registered in the EWOG-MDS 1998 & 2006 trials. Data integration was performed in a subset of patients with available exome sequencing (n=50) and expression profiling (n=15) data.
Results: Systematic DNA methylome analysis of JMML samples identified three subgroups with low, intermediate and high methylation levels (LM, IM, and HM). Detailed analysis of the validation cohort not excluding the Noonan patients identified an association of methylation groups with clinical features. The HM subgroup (n=41) was enriched for high-risk characteristics: All HM cases had elevated levels of HbF, 88% were older than 2 years at diagnosis, 74% had low platelets (<70/nl), and 66% carried somatic *PTPN11* mutations. In contrast, the LM subgroup (n=62) was enriched for patients with low-risk disease: All 18 patients with Noonan syndrome, 13/14 patients with CBL syndrome, and 15/19 patients with *NRAS* mutations were assigned to the LM group. The IM group (n=45) was enriched for cases with monosomy 7 and somatic *KRAS* mutations. The unfavorable risk profile in the HM group translated into poor 5-year survival (HM 57%, LM 87%; log rank p<0.01) and a high incidence of relapse after HSCT (HM 48%, LM 9%; Gray's test p=0.01). In a multivariate Cox regression model, only methylation group (HM *vs* LM: RR 10.9 [1.8-66.2]) and *PTPN11* mutation status (PTPN11-mutant *vs* other: RR 3.3 [1.2-8.9]) remained as independent prognostic factors for CIR (p=0.01).
JMML-specific differentially methylated probes were significantly enriched for regions decorated with H3K27me3 or PRC2 components and for genes associated with oncogenic RAS-signaling. Integrative analysis of genetic and epigenetic events in these cases identified additional gene alterations leading to frequent co-occurrence of ≥2 mutations activating the RAS-RAF-MEK-ERK pathway in the HM and IM subgroups. This finding was paralleled by a significant up-regulation of *DNMT1* and *DNMT3B* expression suggesting aberrant activation of the DNA methylation machinery in this context.
Summary/Conclusions: Our integrated approach identified three JMML subgroups characterized by distinct clinical and biological features. We provide evidence for a molecular mechanism by which additional genetic events, presumably further activating the RAS-RAF-MEK-ERK pathway, mediate DNA hypermethylation via up-regulation of DNMTs in more aggressive JMML cases.

Background: The molecular and phenotypic correlates of cytogenetic abnormalities in primary myelofibrosis (PMF) have been widely investigated. This information in post-polycythemia vera (post-PV) and post-essential thrombocythemia (post-ET) myelofibrosis (referred to as secondary myelofibrosis, SMF) is scant. The MYSEC project (Myelofibrosis Secondary to PV and ET Collaboration) collected 781 SMF patients in Europe and United States and recently disclosed phenotype-genotype associations in SMF (Leukemia, 2017).
Aims: The primary objective of this study is to report cytogenetic abnormalities in SMF on a large scale and to assess molecular and phenotypic correlations of cytogenetic abnormalities. In addition, prognostic relevance of different cytogenetic patterns is investigated.
Methods: Diagnosis of SMF was performed according to the IWG-MRT criteria (2008). The MYSEC study was approved by the Review Board of each Institution and conducted in accordance with the Declaration of Helsinki. Bone marrow cytogenetic analysis was made at time of SMF diagnosis and considered evaluable if at least 20 metaphases were available. Results were described according to the International System for Human Cytogenetic Nomenclature. Karyotype was defined abnormal if a structural or numeric chromosomic alteration was present in at least two metaphases. The presence of three or more aberrations defined a complex karyotype; two or more distinct autosomal monosomies or single autosomal monosomy associated with at least one structural abnormality defined monosomal karyotype (MK). Continuous values were compared via non-parametric Mann-Whitney U tests, with Holm corrections for multiple testing; categorical feature counts were compared with Fisher's exact tests. Time-to-event analysis used Kaplan-Meier estimators and Cox models for regression.
Results: Within the whole cohort of 781 SMF patients, 376 had cytogenetic data. Cytogenetic abnormalities were reported in 128 (34.1%) cases: 72 (60%) were sole, 22 (18.3%) double, 26 (21.7%) complex, 11 (9.2%) MK (all included in complex karyotype) and eight unknown. The most prevalent individual abnormalities were 20q- (25%), 13q- (20.8%), +8 (8.3%) and +9 (5.6%). Patients with post-PV MF had significantly higher frequency of abnormal karyotype than those with post-ET MF (*P*=.012). Chromosomal abnormalities did not cluster differently among the different genotypes (*JAK2, CALR*, *MPL* and triple negativity*)*. Abnormal karyotype was significantly associated with lower platelet count (*P*=.004), larger spleen size (*P*=.016), higher circulating blasts (*P* <.001) and presence of constitutional symptoms (*P*=.014) at the time of SMF diagnosis. Within abnormal karyotypes, we found that patients with MK tended to have lower platelet count (*P*=.04) with respect to those with sole aberrations. Overall survival (OS) was significantly inferior in patients with abnormal karyotype (*P*=.012), even adjusting for SMF diagnosis type (*P*=.02). When investigating OS according to different abnormalities, we found that patients with MK have inferior OS respect to those with sole abnormality (*P* <.0001) (Figure 1).

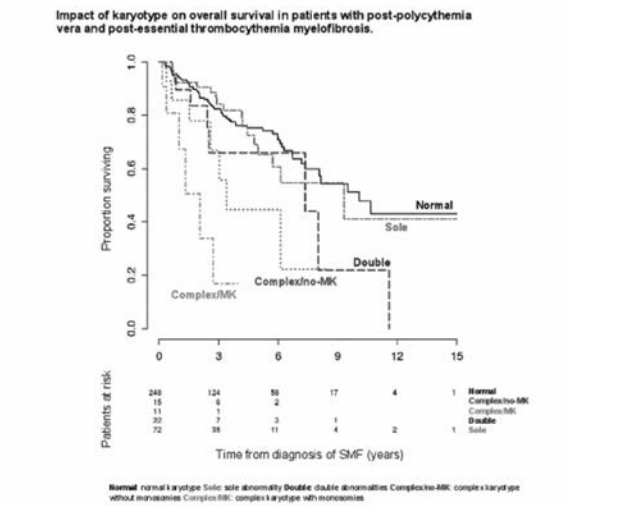

Figure 1.

Summary/Conclusions: Abnormal karyotype was found in 34.1% of SMF patients at diagnosis and was over-represented in post-PV MF. No different distribution was detected among genotypes. Abnormal karyotype was associated with lower platelet count, larger splenomegaly, higher circulating blast cells and presence of constitutional symptoms. Concerning outcome, the presence of abnormal karyotype implied inferior survival and, among subtypes, MK remained the most powerful predictor.

P352

MUTATIONAL LANDSCAPE OF MYELODYSPLASTIC SYNDROME/ MYELOPROLIFERATIVE NEOPLASM - UNCLASSIFIABLE

P. Bose[1,*], A. Nazha[2], R. Komrokji[3], M. Savona[4], K. Patel[5], S. Pierce[1], N. Al Ali[3], A. Sochacki[4], A. Shaver[6], N. Daver[1], C. DiNardo[1], G. Garcia-Manero[1], C. Bueso-Ramos[5], H. Kantarjian[1], M. Sekeres[2], J. Maciejewski[7], S. Verstovsek[1]

[1]Leukemia, University of Texas MD Anderson Cancer Center, Houston, [2]Hematology and Medical Oncology, Cleveland Clinic, Cleveland, [3]Malignant Hematology, Moffitt Cancer Center, Tampa, [4]Medicine, Vanderbilt University/Vanderbilt-Ingram Cancer Center, Nashville, [5]Hematopathology, University of Texas MD Anderson Cancer Center, Houston, [6]Hematopathology, Vanderbilt University/Vanderbilt-Ingram Cancer Center, Nashville, [7]Translational Hematology and Oncology, Cleveland Clinic, Cleveland, United States

Background: MDS/MPN-U is a rare, poorly characterized myeloid neoplasm within the MDS/MPN category in the World Health Organization (WHO) classification. A median survival of 12.4 months from time of referral was previously reported for a cohort of 85 patients with MDS/MPN-U seen at the MD Anderson Cancer Center (MDACC, DiNardo *et al. Leukemia* 2014). The International Prognostic Scoring System (IPSS) for MDS (Greenberg *et al. Blood* 1997) discriminated amongst prognostically distinct categories in that cohort, while neither the IPSS for primary myelofibrosis (PMF, Cervantes *et al. Blood* 2009) nor the revised IPSS (IPPS-R) for MDS (Greenberg *et al. Blood* 2012) did. Median survival of 21.4 months from the time of diagnosis was reported in a multi-institutional cohort (n=69, Wang *et al. Blood* 2014). Information on the genomic landscape of MDS/MPN-U is limited to one report on the frequency of *SETBP1* mutations (8.3%, Meggendorfer *et al. Leukemia* 2013).
Aims: To describe the mutational landscape of MDS/MPN-U using targeted multi-gene sequencing.
Methods: Targeted sequencing was performed on DNA from 97 patients with MDS/MPN-U (diagnosed per WHO 2008 criteria but excluding refractory anemia with ringed sideroblasts and thrombocytosis) seen across 4 US institutions (MDACC, 43; Cleveland Clinic, 29; Moffitt Cancer Center, 16; Vanderbilt University, 9). Gene panels used varied between institutions, with 20 genes (*ASXL1, CBL, DNMT3A, ETV6, EZH2, IDH1, IDH2, JAK2, KIT, NPM1, NRAS, PHF6, RUNX1, SETBP1, SF3B1, SRSF2, TET2, TP53, U2AF1, ZRSR2*) in common.
Results: Mutational frequencies for the 20 genes tested in all 97 patients were as follows: *TET2,* 28%; *ASXL1,* 27%; *JAK2,* 25%; *SRSF2,* 22%; *EZH2,* 15%; *SF3B1,* 12%; *RUNX1,* 12%; *ZRSR2,* 11%; *SETBP1,* 11%; *U2AF1,* 11%; *NRAS,* 10%; *DNMT3A,* 9%; *TP53,* 8%; *CBL,* 4%; *ETV6,* 4%; *NPM1,* 4%; *IDH2,* 2%; *KIT,* 2%; *PHF6,* 1% and *IDH1,* 0%. In addition, the frequency of mutations in ten other genes of interest in hematologic malignancies was assessed: *BRAF*, 0% (n=52); *CSF3R*, 4% (n=52); *CALR*, 4% (n=53); *MPL*, 3% (n=68); *MLL*, 1% (n=72); *STAG2*, 6% (n=72); *CEBPA*, 4% (n=73); *KRAS*, 4% (n=81); *PTPN11*, 4% (n=82) and *FLT3*, 2% (n=82). Median survival for the whole cohort (n=97) was 12.4 months (range, 1-173). The 43 MDACC patients in this analysis were included in the cohort of 85 previously reported by DiNardo *et al.* Median age was 70 years (21-89). Median (range) values for leukocytes, neutrophils, hemoglobin, platelets and bone marrow blasts at the time of sample collection for sequencing were 13.4 (1-179) x 10^9/L, 7.9 (0.4-152.4) x 10^9/L, 9.1 (3.1-15) g/dL, 123 (6-1168) x 10^9/L and 2% (0-17), respectively. On univariate analysis (n=97), only the presence of *EZH2* and *ZRSR2* mutations were associated with trends towards statistical significance for survival. Mutated *EZH2* adversely impacted survival (p=0.056), while mutated *ZRSR2* had a favorable impact on survival (p=0.074). The IPSS-R for MDS was useful to differentiate between risk groups with different survival times (p=0.065) while the dynamic IPSS for PMF (Passamonti *et al.* Blood 2010) was not (p=0.39). On multivariate analysis, only *EZH2* mutations and IPSS-R very low risk (*versus* all other categories combined) were statistically significantly associated with inferior and superior survival, respectively.
Summary/Conclusions: In this cohort of 97 patients with WHO-defined MDS/MPN-U, mutations in genes encoding epigenetic regulators (*e.g.*, *TET2, ASXL1, EZH2*), spliceosome components (*e.g.*, *SRSF2, SF3B1, ZRSR2, U2AF1*), signaling molecules (*JAK2, NRAS*), the transcription factor *RUNX1* and *SETBP1* were found at frequencies ≥10%. Although the analysis is limited by small numbers, *EZH2* mutations were independently associated with poor survival. This represents the largest cohort of patients with MDS/MPN-U interrogated for mutations in multiple genes to date.

P353

GENOME WIDE DNA METHYLATION PROFILING IS PREDICTIVE OF OUTCOME IN JUVENILE MYELOMONOCYTIC LEUKEMIA

E. Stieglitz[1,2,*], T. Mazor[3], A. Olshen[2,4], H. Geng[5], D. Lipka[6], C. Plass[6,7], C. Flotho[7,8], J. Costello[3], M. Loh[1,2]

Background: Juvenile myelomonocytic leukemia (JMML) is a myeloproliferative disorder of childhood that is initiated by mutations in the Ras pathway. Outcomes in this disease vary dramatically from resolution with minimal or no therapy to relapse despite hematopoietic stem cell transplantation. Identifying biomarkers to distinguish patients with aggressive disease courses from those who can receive minimal therapy remains a priority for clinicians.
Aims: We utilized an unbiased screening approach to investigate genome-wide DNA methylation in newly diagnosed JMML patients. We then sought to determine whether a specific DNA methylation signature was capable of predicting outcomes in this heterogeneous disease, with a particular emphasis on identifying a biomarker predictive of spontaneous resolution.
Methods: Genome wide DNA methylation analysis was carried out using the Illumina 450k BeadChip platform in a discovery cohort of 39 well-characterized patients with JMML enriched for those who experienced spontaneous resolution without chemotherapy. A separate cohort of 40 patients with JMML was then used for validation. Of note, patients with Noonan syndrome were excluded from both cohorts. All 79 patients were then compared to 22 healthy controls between 1 and 5 years of age using peripheral blood derived DNA.
Results: JMML patients with aggressive disease have a distinctly hypermethylated DNA profile at the most variable CpG sites compared to patients with less aggressive disease as well as healthy controls. Methylation patterns did not differ based on the tissue of origin (peripheral blood, splenic tissue, or bone marrow) and were similar between monocyte enriched cell populations and unsorted mononuclear cells. Unsupervised clustering of the discovery cohort based on the most highly variable CpG sites (top 0.5% ranked by standard deviation, 1527 CpG sites) identified three clusters. For patients in the cluster with the lowest levels of methylation, only one patient out of 15 (7%) had an event at 4 years (95% confidence interval [CI], 2-32%). This compared to 45% (5/11) (CI, 17-77%) for patients in the cluster of intermediate levels of methylation and 61% (8/13) (CI, 32-86%) in those patients with the highest level of methylation. The proportion of patients with events differed significantly by cluster (p=0.0039) and remained independently prognostic in multivariable analysis (p=0.033) in the context of age and the number of somatic mutations at diagnosis. We next sought to validate our findings in an independent cohort of 40 patients. We classified each patient in the validation cohort into one of the three clusters defined by the discovery cohort. The proportion of patients having an event at four years was 8% (1/12) (CI, 0-38%) in those with the lowest level of methylation. This compared to 36% (4/11) (CI, 11-69%) for patients with intermediate levels of methylation and 76% (13/17) (CI, 50-93%) for those with the highest levels of methylation. We then compared our combined cohort of 79 JMML patients with 22 healthy, age-appropriate controls. Remarkably, using the same set of CpG sites defined in the discovery cohort, 27/79 JMML patients clustered more closely with the controls than with other patients. Of these 27 patients, 14 (52%)

experienced spontaneous resolution and only two (7%) experienced an event at 4 years.
Summary/Conclusions: Using a genome-wide methylation analysis, patients with the lowest degree of DNA methylation within the most variable CpG sites had improved event free survival compared to patients with higher degrees of methylation. Interestingly, patients who experienced spontaneous resolution of their disease clustered more closely with healthy controls than to patients with aggressive JMML. DNA methylation is a robust biomarker independently capable of predicting outcome and should be tested prospectively in the context of clinical trials.

P354

LEUKEMIC TRANSFORMATION OF MYELOPROLIFERATIVE NEOPLASMS: IS NGS PROFILE THE BEST PROGNOSTIC BIOMARKER?

V. Geoffroy[1,*], F. Courtier[2], A. Charbonnier [1], E. D'Incan[1], C. Saillard[1], B. Mohty[1], D. Birnbaum[2], M.-J. Mozziconacci[3], A. Murati[3], N. Vey[1], J. Rey[1]
[1]Hematology - Leukemia Department, [2]CRCM, [3]Biopathology Department, Institut Paoli Calmettes, Marseille, France

Background: Leukemic transformation occurs in 8% to 23% of myelofibrosis patients in the first 10 years after diagnosis and in 4% to 8% of polycythemia vera and essential thrombocytosis patients within 18 years of diagnosis and is almost always fatal.
Aims: We retrospectively analyzed the survival outcome of patients with myeloproliferative neoplasms (MPNs) who progressed to acute myeloid leukemia (AML) based on the treatments received, response, different prognosis groups according to the (ELN) and based on a next-generation DNA sequencing profile (NGS).
Methods: A total of 72 patients diagnosed in our institute with AML secondary to MPNs between 2000 and 2016 were retrospectively analyzed. NGS was performed in 44 cases. Mutations found by NGS were classified according three different cellular functions of interest (Tumors suppressor (*TP53*), ADN/Histones' epigenetic (*DNMT3A, EZH2,IDH1/2,ASXL1*) and alternative splicing (*SRSF2,U2AF1,ZRSR2,PRPF8,SF3B1*)) and three groups were determined: Group A: patients without altered cellular function; Group B: patient with one altered function; Group C: patients with more one altered functions. AML treatment response was evaluated according Mascarenhas' proposed criteria for response assessment of AML secondary to MPNs. Overall survival (OS) was calculated according the different treatments, treatment response and NGS profiles.
Results: 72 patients who developed AML secondary to MPNs were included in the study.43.6% (N=31) had prior ET, 25% (N= 18) PV, 20.8% (N=15) PMF and 11.1% (N=8) secondary myelofibrosis. The median age at AML transformation was 70 (range: 38-89). The median time to AML transformation from MPNs diagnosis was 108 months (range: 2.4-408). Among these 72 AML, 5.6% (N=4) belonged to the favorable risk category according to ELN 2017, 13.9% (N= 10) belonged to the intermediate risk category and 55.6% (N=40) to the adverse risk category. 45.8% (N=33) patients were treated with intensive chemotherapy (IC), 15.3% (N=11) with azacitidine (AZA) and 38.9 (N=28) with supportive care (BSC). Median OS was 4.5 months (range, 0.1-65), with no significant difference between the three ELN 2017 risk categories (respectively 2.5 months (range: 1-9), 5.5 months (range: 1-60) and 5 months (range: 1-36) in the favorable, intermediate and adverse risk categories). Patients who received IC ($p<0.01$) or AZA ($p<0.05$) have a significant better OS (median OS of 7 months (range: 0.5-65) and 8.5 months (range: 3-24) respectively) than patients who received BSC (median OS of 2 months, range: 0.1-36). However, there is no significant difference between the IC and HMA groups ($p=0.44$). 7 Patients in Complete Cytogenetic Response (CCR) or Acute Leukemia Response-Complete (ALR-C) received an alloSCT had a better median OS than the 9 patients who did not (23 *vs* 6.5 months, $p=0.063$). Patients with group A and B NGS profiles have a significant better median OS (respectively 14 and 8 months) than Group C (3 months) ($p <0.05$).
Summary/Conclusions: Our results confirm the poor outcome of patients with secondary AML treated with IC and suggest that AZA provides comparable OS. ELN2017 risk stratification predicted poorly patients outcome although a NGS-based classification performed better.

P355

INCIDENCE AND OUTCOME OF SECONDARY NON HEMATOLOGICAL CANCERS IN ADULT PATIENTS WITH MASTOCYTOSIS

[1]GISM-Gruppo Interdisciplinare per lo Studio della Mastocitosi, Azienda Ospedaliera Universitaria Integrata di Verona, [2]Department of Medicine, Section of Hematology, University of Verona, [3]Allergy Unit, Azienda Ospedaliera Universitaria Integrata di Verona, Verona, [4]Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, [5]Department of Molecular Medicine, University of Pavia, Pavia, [6]CRIMM-Center of Research and Innovation of Myeloproliferative Neoplasms, Azienda Ospedaliero-Universitaria Careggi, [7]Department of Experimental and Clinical Medicine, University of Florence, Florence, [8]Oncohematology Unit, Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, Milan, [9]DIMES-Department of Expermimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, [10]Hematology Unit, Santa Maria delle Croci Hospital, Ravenna, Italy

Background: Mastocytosis is a clonal disease characterized by heterogeneous manifestations and a normal life expectancy in the majority of cases. In such a condition, it is important to ascertain if other diseases, and particularly solid malignancies, can worsen the prognosis.
Aims: To assess incidence and outcome of secondary primary malignancies (SPM) in adult mastocytosis patients.
Methods: We performed a retrospective analysis of 826 adult (>18 years at diagnosis) mastocytosis patients diagnosed and regularly followed in 6 Italian Institutions. SPM were defined as *de novo* cancers diagnosed after mastocytosis. We excluded from the analysis non-melanoma skin cancers due to the possible under-reporting of such neoplasms by patients themselves. Also, we did not consider newly hematological neoplasms, as they mainly represent a progression from Systemic Mastocytosis (SM) to SM with an Associated Hematological Neoplasm (AHN). Standardized Incidence Ratio (SIR) was calculated as the ratio between the observed cases in our cohort and the expected cases in the sex- and age-matched general Italian population in the same time period (these data were retrieved from http://www.registri-tumori.it). Times to event (patient-years) were calculated from the diagnosis of mastocytosis to the date of SPM diagnosis, death, or last contact, whichever comes first. Survival curves were estimated according to the Kaplan-Meier method.
Results: Males were 450 (54%). Median age at diagnosis was 49.3 years (range 19-84). Median follow-up was 2.3 years (range 0-41). Subtype diagnoses were: Cutaneous Mastocytosis (n=46), Indolent SM (n=633), Smoldering SM (n=10), SM-AHN (n=34), Aggressive SM (n=47) and Mast cell leukemia (n=2). Fifty-four patients were classified as having mastocytosis in the skin. Overall, 42 patients had a history of malignancies prior to the diagnosis of mastocytosis: in these patients we did not detect any relapse of their prior malignancy after the diagnosis of mastocytosis. A total of 35 SPM were diagnosed in 34 patients (4.1%). Median age at SPM was 56.4 years (range 37-76). Median time from mastocytosis to SPM was 22 months. The overall rate of SPM was 12.8 per 1,000 person-years (95%CI: 9.1-17.6) while the rate in the general adult population was 7.6 per 1,000 person-years (95%CI: 7.5-7.7) resulting in an increased hazard ratio of 1.7 (95%CI: 1.2-2.3). The risk for SPM was higher than expected in females (SIR 1.93, 95%CI: 1.2-3.1) while it was not significantly increased in males (SIR 1.46, 95%CI: 0.9-2.4). We found a clearly increased risk for melanoma (n=8, SIR 15.9, 95%CI: 7.9-31.9) and thyroid cancer (n=3, SIR 9, 95%CI: 2.9-27.9) while a non-significant increased risk was found for prostate cancer in males (n=5, SIR 2.06, 95%CI: 0.8-4.9) and breast cancer in females (n=3, SIR 1.7, 95%CI: 0.5-5.3). All the other malignancies were sporadic (one or two cases for each cancer type) and comparison to the general population was not significant. The death rate in patients with SPM was 14.7% with a median overall survival (OS) from SPM diagnosis of 38 months. OS was significantly inferior in patients with SPM as compared to patients without secondary neoplasia (5-year OS 77.6% *vs* 93.7% respectively, $p=.019$) (Figure 1).

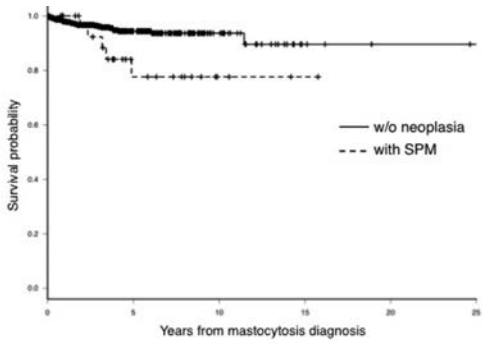

Figure 1.

Summary/Conclusions: Patients with mastocytosis may have a significantly higher risk of developing a secondary non hematological cancer as compared to the matched general population. Careful follow-up of these patients is warranted as the rate of malignancies may increase over time and reduce life expectancy.

Background: Colony stimulating factor 3 receptor gene (CSF3R)-mutated chronic neutrophilic leukemia (CNL) is a rare chronic myeloproliferative neoplasm. There is the limited information on the clinical course of CNL.
Aims: To explore the clinical course of patients with *CSF3R*-mutated CNL and identify risk factor(s) associated with survival.
Methods: A retrospective study was conducted to assess natural history and identify risk factor(s) for survival in patients with *CSF3R*-mutated CNL. Survival analysis was performed by the Kaplan-Meier method taking the interval from the date of diagnosis to death or last contact. The log-rank test was used to compare survival data. Cox regression model was used for multivariable analysis.
Results: Data of 47 patients with CSF3R-mutated CNL were collected and analyzed. 35 (76%) patients were male. Median age was 62 years (range, 16-92 years). At diagnosis, 17 (36%) patients had fatigue, 2 (4%) had a fever, 8 (17%) experienced diarrhea or abdominal discomfort, 20 (43%) were asymptomatic and leukocytosis had been mostly an incidental laboratory finding. 20 (43%) patients had palpable splenomegaly, and 4 (9%), palpable hepatomegaly. PB parameters, median and (range), were WBC 42.4×10^9/L (14.4-217.0), hemoglobin 100g/L (42-157), platelets 165×10^9/L (17-570), blast percentage 0% (0-10), neutrophil percentage 82% (70-99). The median of blast cells in bone marrow were 1% (range, 0-12%). 46 (98%) patients were in the chronic phase and 1 (2%) in the accelerated phase at diagnosis. Most of the CSF3R mutations was T618I (n=45, 96%), others were T568M (n=1, 2%) and O706T (n=1, 2%). 34 (72.3%) patients and 41 (87.2%) patients were screened for ASXL1 and SETBP1 mutations, respectively. 21 (61.8%) patients harbored ASXL1 mutation and 22 (53.7%) harbored SETBP1 mutation. All patients were BCR-ABL1, PDGFR and FGR mutation negative, 2 were CALR mutation and JAK2V617F mutation positive, respectively. Hydroxyurea was the most frequently used therapy (n=46). Other therapies included interferon-a (n=7), hypomethylating agents (n=4), thalidomide (n=2), ruxolitinib (n=1), imatinib (n=3), dasatinib (n=1), chemotherapy (n=6), and transplant (n=2). With a median follow up of 17 months (range, 2-103 months), 7 patients progressed to blastic phase or acute myeloid leukemia (n=6) or myelodysplastic syndrome (n=1), 17 patients died. Survival rate at 30 months was 55%. Median survival was 39 months (95% CI 8.5-69.5). Multivariate analysis showed that WBC >40×10^9/L (HR=3.26, 95% CI 1.14-9.30, p= 0.027) was the sole risk factor for survival. However, SETBP1 or ASXL1 mutation was not associated with survival.
Summary/Conclusions: High WBC count was independently predictive of shortened survival in patients with CSR3R-mutated CNL.

P357

CLINICAL PHENOTYPE AND OUTCOME OF ESSENTIAL THROMBOCYTHEMIA AND PREFIBROTIC MYELOFIBROSIS DIAGNOSED ACCORDING TO THE REVISED 2016 WHO DIAGNOSTIC CRITERIA

E. Rumi[1,2], E. Boveri[3], M. Bellini[1], D. Pietra[2], V. Ferretti[1], E. Roncoroni[2], C. Cavalloni[2], M. Ciboddo[1,*], I. Casetti[1], P. Benvenuti[1], C. Astori[2], M. Cazzola[1,2]

Background: The World Health Organization (WHO) classification system for myeloid neoplasms was recently revised in 2016. The revised WHO criteria underscore the importance of differentiating prefibrotic PMF (prePMF) from "true" essential thrombocythemia (ET) as these two entities have different clinical outcomes. For these reasons, standardization of morphologic findings in the bone marrow biopsy and an explicit definition of minor clinical criteria for the diagnosis of prePMF have been added (anemia, leukocytosis >11 x10^9/L, palpable splenomegaly, increased LDH).
Aims: To compare the clinical phenotype at diagnosis and the outcome of ET and prePMF diagnosed according to the new 2016 WHO criteria.
Methods: We identified in our database all patients affected with ET, prePMF and PMF diagnosed according to 2008 WHO criteria who satisfied these two requirements: a bone marrow fibrosis grade 0-1 at diagnosis and at least one DNA sample to define the mutational status. Firstly, the bone marrow morphology of all 404 identified patients was reviewed by an expert pathologist. Then, we reclassified patients according to the new 2016 WHO criteria as follows: patient with ET morphology were classified as ET, patients with PMF morphology and at least one clinical criteria (leukocytes, anemia, increased LDH, splenomegaly) were classified as prePMF, patients with PMF morphology but without clinical criteria were classified as myeloproliferative neoplasms unclassifiable (MPNu).
Results: According to the new criteria our cohort included 269 patients with ET, 109 patients with prePMF and 26 with MPNu. By comparing clinical phenotype at diagnosis in prePMF, MPNu, and ET respectively, we observed that prePMF showed higher leukocyte count, lower hemoglobin levels, higher platelet count, higher LDH values, higher number of circulating CD34-positive cells, and showed more frequently splenomegaly (Table 1). The higher frequency of *CALR* mutations in prePMF compared to ET might contribute to the high level of platelet count observed in prePMF. ET and MPNu did not differ in terms of leukocyte count, hemoglobin, platelet count, LDH, circulating CD34-positive cells and splenomegaly (Table 1). The 26 patients with MPNu were not further considered in the analysis of disease complications and overall survival due to the low number. PrePMF patients had lower overall survival (overall survival at 10 years 86.4% *vs* 96.6%, *P* <.001) and a trend to a higher incidence of leukemic evolution (cumulative incidence of acute myeloid leukemia at 10 years 2.3% *vs* 1.9%, *P* .067) compared to ET patients, while they did not differ in terms of thrombotic complications (cumulative incidence of thrombosis at 10 years 18.5% *vs* 18%, P>.90). Finally, we analyzed the subgroup of "old" ET diagnosed according to 2008 WHO criteria. Of 358 "old" ET, 268 were reclassified as ET, 25 as MPNu and 65 as prePMF. The "old" ET reclassified as prePMF had a higher risk of overt myelofibrotic evolution compared to the "old" ET reclassified as ET (cumulative incidence of overt myelofibrosis at 10 years 9.7% *vs* 0%, *P*=.033).

Table 1.

Clinical features of patients according to the new 2016 WHO criteria

	ET (A)	MPNu (B)	prePMF (C)	*P*		
N°	269	26	109	A vs B	B vs C	A vs C
Sex (male/female)	105/164 (39%/61%)	7/19 (27%/73%)	55/54 (51%/49%)	.291	.047	.051
Age at onset, years, median (range)	53.1 (17.4-88.5)	44.3 (18.2-79.4)	54.7 (15.6-83)	.015	.019	.938
Hemoglobin, g/dL, median (range)	14.2 (8.4-17.7)	13.5 (12.1-15.8)	13.5 (8.5-17.1)	.101	.390	<.001
WBC count, x 10^9/L, median (range)	8.3 (4.2-28)	8.1 (5.3-10.6)	10.3 (4.7-23.5)	.117	<.001	<.001
PLT count, x 10^9/L, median (range)	677 (450-2810)	765 (414-1825)	823 (97.8-3000)	.057	.643	<.001
Splenomegaly, no. (%)	12 (4.5%)	0 (0%)	31 (29%)	.609	.001	<.001
LDH, mU/mL, median(range)	200 (77-472)	194 (100-220)	265 (66-935)	.133	<.001	<.001
Circulating CD34+ cells, x 10^9/L, median(range)	3.6 (0.4-13.2)	3.6 (0.6-26.5)	6.6 (0.2-94.1)	>.900	.001	<.001
Mutational status, no. (%)				.419	.774	<.001
JAK2 V617F	179 (66.5%)	17 (65.3%)	57 (52.3%)			
CALR	48 (17.8%)	7 (26.9%)	39 (35.8%)			
MPL	9 (3.4%)	1 (3.9%)	7 (6.4%)			
Triple neg	33 (12.3%)	1 (3.9%)	6 (5.5%)			

Summary/Conclusions: ET and prePMF diagnosed according to 2016 WHO criteria are two entities with a different clinical phenotype at diagnosis and a different outcome. The clinical phenotype at disease onset of MPNu and ET is similar.

Background: The minimal effective treatment in Essential Thrombocythemia (ET) patients is tailored mainly on the basis of thrombotic risk scores (*primum non nocere).*The Revised International Prognostic Score for Thrombosis in ET (R-IPSET-Th) is based on different combinations of Age >60 yrs (Age >60), JAK2 V617F mutation (JAK2+) and Prior Thrombosis (PrTh+).
Aims: To validate the R-IPSET-Th in a cohort of ET patients reclassified according to the WHO 2016 criteria.
Methods: The web-based Registro Italiano Trombocitemie (RIT) recruited since 2005 patients with thrombocythemic bcr/abl negative chronic myeloproliferative neoplasms (MPN). ET patients (reclassified according to WHO 2016 criteria) with complete information (characteristics at diagnosis, antiplatelet and/or cytoreductive treatment, date and description of thrombotic events during the follow-up) were considered for this analysis. According to the R-IPSET-Th score, the patients were divided in 4 thrombotic risk groups: Very Low Risk (VLR: Age <60, absence of JAK2 mutations, no PrTh+), Low risk (LR: only JAK2+), Intermediate Risk (IR: only Age >60), High Risk (HR: PrTh+, or Age >60 with JAK2+). The rates (n and%, n/100 pt-yrs) of first thrombotic events during the follow-up (Th-FUP) were reported for each risk group. The thrombosis free survival (TFS, time from diagnosis to the first thrombosis) was determined for each risk group (Kaplan Meier analysis), and the curves were compared with the log-rank test. The concordance between the R-IPSET-Th score and the IPSET-Th score was evaluated (Harrell C concordance index).
Results: Overall, 734 ET patients were analyzed (females 62%). Data at diagnosis were: Age >60 in 286 (39%), JAK2+ in 417 (57%), and PrTh in 126 (17%) patients. Moreover: CVRFs in 66%, PLT >1000 x 10^9/L in 17%, and WBC >10 x 10^9/L in 21% of patients. The patients in the 4 R-IPSET-Th score risk groups were: VLR 193 (26%), LR 197 (27%), IR 79 (11%), HR 265 (36%). The median follow-up was 12, 12, 9, and 11 years, respectively (whole cohort, 11 years). The rates of treatment were: 88%, 94%, 92%, 91%, respectively (whole cohort, 91%), with anti-platelet drugs (mainly low dose aspirin); 71%, 62%, 95%, 95%, respectively (whole cohort, 80%), with cytoreductive drugs (mainly hydroxycarbamide). The Th-FUP were 103 (14.0%), with a rate increasing with the risk score (p <0.001): in VLR (n 15, 8%), in LR (n 20, 10%), in IR (n 12, 15%), in HR (n 56, 21%). The Th-FUP/100 pt-yrs increased (p <0.01) as follows: 0.60%, 0.79%, 1.61%, and 1.91%, respectively. TFS progressively decreased (p <0.001) from VLR group to HR group (Figure 1). In detail, the probability of TFS was 0.98, 0.97, 0.94, 0.88 at 5 years, and 0.85, 0.87, 0.78, 0.54 at 20years. The patient stratification according to the R-IPSET-Th and the IPSET-Th scores showed a concordance of 0.82 (Harrell C index).

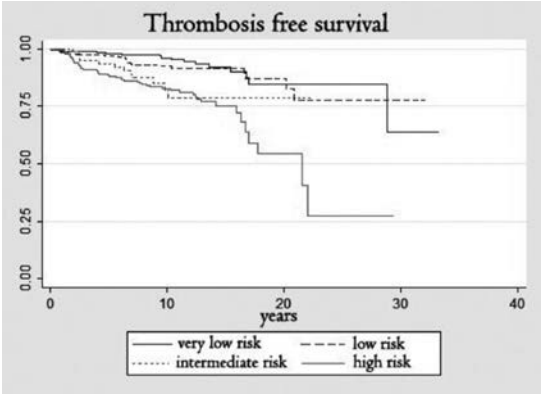

Figure 1.

Summary/Conclusions: In this study of the Registro Italiano Trombocitemie (RIT), we confirmed that the Revised International Prognostic Score for Thrombosis in ET (R-IPSET-Th) separated ET patients in 4 groups with increasing risk of thrombosis during the follow-up (p <0.001). According to the R-IPSET-Th score, an over-treatment seems to have occurred in this cohort of ET patients (anti-platelets in almost all cases, and cytoreduction in around 2/3 of VLR and LR cases), probably because other adjunctive risk factors have been considered.

P359

CORRELATIONS BETWEEN INFLAMMATORY BIOMARKERS AND INDIVIDUAL SYMPTOMS EXPRESSED BY MYELOFIBROSIS PATIENTS IN THE COMFORT-I TRIAL: ANALYSIS OF BASELINE ASSOCIATIONS AND CHANGES OVER TIME

H. Geyer[1,*], R. Scherber[2], H. Kosiorek[1], S. Verstovsek[3], B. Langlais[1], L. Padrnos[1], J. Palmer[1], A. Dueck[1], R. Mesa[1]
[1]Mayo Clinic, Phoenix, AZ, [2]OHSU, Portland, OR, [3]MD Anderson, Houston, TX, United States

Background: Myelofibrosis (MF) is characterized by significant inflammation driven by clonal dysregulation and subsequent disruption of cellular signaling cascades. Studies have confirmed a close relationship between circulating inflammatory BMKs and baseline symptom burdens, along with the potential to mitigate symptoms upon improvement of these proteins (Dueck Blood, 2013). To date, no study has evaluated the correlations between elevated biomarkers (BMKs) and specific MF symptoms.
Aims: In this analysis of the phase-III placebo controlled COMFORT-I study we investigated the relationships between blood BMKs and individual MF symptoms at baseline and post-treatment with ruxolitinib.
Methods: Biomarker levels at baseline, week 4 and 24 were measured along with MF symptoms (MFSAF 2.0-Mesa JCO 2013; collected during blinded phase of COMFORT-I). Patients were randomized to ruxolitinib *vs* placebo. BMKs were assessed using Rules-Based Medicine, Inc. (Austin, TX) Human MAP panel. Associations between the individual symptoms measured within the MFSAF and log2-transformed biomarker data were investigated at baseline using Spearman correlations. Mixed models were used to assess symptom and BMKs changes over time. Models included terms for visit, arm, visit-by-arm interaction, age, sex, and body mass index (BMI).
Results: *Study Population*. A total of 309 subjects were randomized in COMFORT-I with median age of 68 (range 40-91). Approximately 46% of patients were female and 50% had primary myelofibrosis (61% high risk). All 309 subjects had BMKs measured at one or more of the three visits included in this analysis, with 308 having biomarker values paired with MFSAF symptom scores at the same visit. *Correlations of Baseline Biomarkers and Symptoms*. Total symptom score (TSS) statistically significantly (p<0.05) correlated with 20 BMKs at baseline (Table 1). For individual symptoms, spleen-related symptoms appeared to statistically significantly correlate more frequently with BMKs at baseline: abdominal discomfort (23 BMKs), feeling full (20 BMKs), and pain under left ribs (19 BMKs). Night sweats, itchiness, and bone or muscle pain significantly correlated with 15, 14, and 10 BMKs each. The BMKs with the strongest correlations (absolute Spearman correlation of at least 0.20 with p<0.001) with at least one symptom included APOA1, EPO, FERRITIN, MIP1A, and PSAF. *Associations with Symptom and Biomarker Change Over the Trial Course.* Twenty BMKs were significantly associated with TSS over time. Like at baseline, BMKs appeared to be more often statistically significantly (p<0.05) associated with spleen-related symptoms over time including 25 and 24 BMKs for abdominal discomfort and feeling full, respectively. Night sweats, pain under left ribs, bone or muscle pain, and itchiness were associated with 20, 12, 12, and 9 BMKs each. Strongest associations (p<0.001) between symptoms and BMKs over time included VCAM1 (4/6 symptoms+TSS), B2MICG (3/6 symptoms+TSS), LEPTIN (3/6 symptoms+TSS), TIMP1 (2/6 symptoms+TSS), TNFRII (2/6 symptoms+TSS), INTLK18 (2/6 symptoms+TSS), and VWD (1/6 symptoms).

Summary/Conclusions: Spleen-related symptoms demonstrate close association with BMKs at baseline as well as BMKs over time, after taking into account age, sex, BMI, and treatment. At baseline and over time, abdominal symptoms remained the most frequently correlated or associated symptoms with biomarker levels. More research is needed to determine the role of some of these key BMKs in altered cellular signaling and potentially targetable pathways for symptom reduction.

Platelet disorders: Basic

NOVEL HETEROZYGOUS ITGB3 P.T746DEL MUTATION INDUCING SPONTANEOUS ACTIVATION OF INTEGRIN AIIBB3 CAUSES AUTOSOMAL DOMINANT MACROTHROMBOCYTOPENIA WITH ABNORMAL AIIBB3 LOCALIZATION

N. Miyashita[1,*], M. Onozawa[2], K. Hayasaka[3], S. Kunishima[4], T. Teshima[1]
[1]Department of Hematology, Hokkaido University Graduate School of Medicine, [2]Department of Hematology, [3]Clinical Laboratory, Hokkaido University Hospital, Sapporo, [4]Department of Advanced Diagnosis, Clinical Research Center, National Hospital Organization Nagoya Medical Center, Nagoya, Japan

Background: Congenital macrothrombocytopenia is a rare platelet disorder and its cause is genetically heterogeneous. Recently, integrin αIIb and β3 mutations have been identified in congenital macrothrombocytopenia patients with platelet aggregation dysfunction. Here, we found a novel, heterozygous *ITGB3* mutation in a pedigree and examined how this mutation contributed congenital macrothrombocytopenia.
Aims: To detect gene mutations responsible for the congenital macrothrombocytopenia in this pedigree and reveal the molecular pathophysiology.
Methods: Whole exome sequencing (WES) was performed to detect gene mutations. Expression and activation state of αIIbβ3 in platelets was evaluated by flow cytometry (FCM) and western blotting (WB). The effects of mutations on αIIbβ3 activation state, phosphorylation of FAK, and morphological changes were analyzed in transfected cells by WB and immunofluorescence staining.
Results: The patients were 56-year-old Japanese woman and 2 of her 3 sons. They had no bleeding tendencies and near-normal bleeding time (Duke's method). Hematological examination revealed their decreased platelet counts (58-86 x 10^9/l) with increase of mean platelet volume (12.8-14.5 fl). In all affected family members, giant platelets were observed on the peripheral blood smears. Platelet aggregation induced by ADP (1-10 μmol/l) and collagen (2 μg/ml) was obviously reduced although that induced by ristocetin (1.5 mg/ml) was within normal limit. The family pedigree indicates that the inheritance pattern is autosomal dominant. Common congenital macrothrombocytopenias, such as *MYH9* disorders, Bernard-Soulier syndrome and type 2B von Willebrand disease were excluded by the absent leukocyte inclusion bodies, normal ristocetin-induced platelet aggregation and normal platelet GPIb/IX expression, normal von Willebrand factor assays, respectively. WES revealed that all affected family members had a heterozygous *ITGB3* p.T746del mutation. FCM showed decreased surface expression level of αIIbβ3 in the affected member's platelets. However WB of platelet lysates showed that there was no difference in the total amount of αIIbβ3 among the affected and unaffected members and normal controls. FCM showed a constitutive activation of αIIbβ3 on the patient's platelets as reflected by the spontaneous binding of PAC-1 antibody. Immunofluorescence staining using CHO cells showed membrane localization of αIIbβ3 in wild-type αIIb/β3-expressing cells and cytoplasmic localization in αIIb/β3 (p.T746del)-expressing cells. *ITGB3* p.T746del led to spontaneous tyrosine phosphorylation of FAK and morphological changes, such as rhomboidal changes, elongated changes, abnormal cytoplasmic protrusions, and membrane ruffling, in transfected cells. FAK inhibitor (1,2,4,5-Benzenetetraamine tetrahydrochloride) hindered the localization change of αIIbβ3 and the morphological changes in transfected cells by dose dependent manner.
Summary/Conclusions: The autosomal dominant heterozygous *ITGB3* p.T746del mutation was found to be responsible for constitutive activation of αIIbβ3 in the patients' platelets as well as transfected cells. It is considered that *ITGB3* p.T746del mutation unclasps the highly conserved membrane proximal complex of αIIb and β3 cytoplasmic tails and renders the activated form. Activation of αIIbβ3 leads to phosphorylation of FAK causing morphological changes in transfected cells, which is considered to reflect abnormal thrombopoiesis leading to the production of giant platelets. We conclude that platelet aggregation dysfunction is due to decrease of αIIbβ3 expression on the platelet membrane surface due to cytoplasmic localization. These results suggest that the gain-of-function mutation around membrane region of αIIbβ3 leads to macrothrombocytopenia with impaired surface αIIbβ3 expression.

CHANGES IN THE GENE EXPRESSION PROFILE OF IMMUNE THROMBOCYTOPENIA PATIENTS TREATED WITH ELTROMBOPAG

J. Bastida[1,*], J. Hernandez-Sanchez[2], A. Rodriguez[2], D. Alonso-Lopez[2], E. Lumbreras[2], M. Lopez-Parra[1], R. Bueno[2], A. Veiga[1], J. Hernandez-Rivas[2], J. Gonzalez-Porras[1]
[1]Department of Hematology, Hospital Universitario de Salamanca-IBSAL, [2]Department of Hematology, IBSAL, IBMCC, CIC, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: Eltrombopag (ETP) is an orally bioavailable, small non-peptide molecule thrombopoietin receptor agonist that stimulates platelet production by a mechanism similar, but not identical to, endogenous thrombopoietin. ETP interacts with the transmembrane domain of thrombopoietin receptor, initiating a JAK/STAT signaling pathway inducing the proliferation and differentiation of the megakaryocytes to increase platelets production.
Aims: To assess the gene expression profile (GEP) and the underlying signaling pathways modified before and during the ETP treatment in chronic immune thrombocytopenia (ITPc) patients.
Methods: ITPc patients (n=14) treated with ETP were evaluated. Complete response (CR) was defined as a platelet count of ≥100x10^3/mm^3 and treatment failure was defined as a platelet count of≤20 x10^3/$mm^3$for 4 consecutive weeks at the highest recommended dose of ETP, a major bleeding event, or the need to change therapy. RNA was isolated from mononucleated cells pre/post ETP treatment. The "paired" GEP of the ITPc patients included the semi-supervised analysis cluster samples before and after (28 day) the treatment with ETP to detect changes attributed to ETP. This paired GEP was showed in Figure 1. The GEP workflow consisted of the following steps: 28-paired samples were hybridized to GeneChip® Human Gene 2.0 ST Array (Affymetrix's). The robust microarray analysis (RMA) algorithm was used for background correction and normalization, while signal expression was calculated by significance analysis of each microarray to provide a robust statistical inference by a permutation method. P-values were provided and adjusted by multiples testing using a false discovery rate (FDR). The pathways and upstream regulators related with the most differentially expressed genes were analyzed by *in silico* analysis tools: Advaita Bio's iPathwayGuide (http://www.advaitabio.com/ipathwayguide)" and DAVID Bioinformatics Resources.
Results: The median age of the 14 ITPc patients enrolled in the study was 77 years (range, 35-87y). 64% patients (n=9) were treated with ETP after ≥2 lines of treatments. Only 3 patients were splenectomized. Median platelet (P) and white blood cell counts (WBC) increased after treated by ETP at day 28. (P and WBC pre: 14,15x10^3/mm^3 and 6,85x10^3/mm^3 *vs* P and WBC post: 132x10^3/mm^3 and 9,1x10^3/mm^3). All but two patients achieved CR (85,7%) and other 2 were considered failure of treatment. Regarding the gene expression profile, *in silico* analysis showed that the expression of 147 genes was modified after ETP treatment; all of them were overexpressed after treatment. Semi-supervised cluster analysis showed 2 groups: pre and post ETP treatment (Figure 1). Pathway analysis revealed that 38 genes were involved in the maintenance of hemostasis, most of them related to platelet activation (*PTGS1, GP1BA* or *GP6*). Interestingly, the paired GEP pointed out *E2F1 and GFI1B* as possible leaders of the increase of the megakaryopoiesis. Other signaling pathways overexpressed by ETP treatment are downstream routes of PI3K/Akt (*GFI1B, JAM3, ITGB3 and ITGA2B*) and platelet activation (*GP6, GP9, GP1BA* or *PTGS1*).

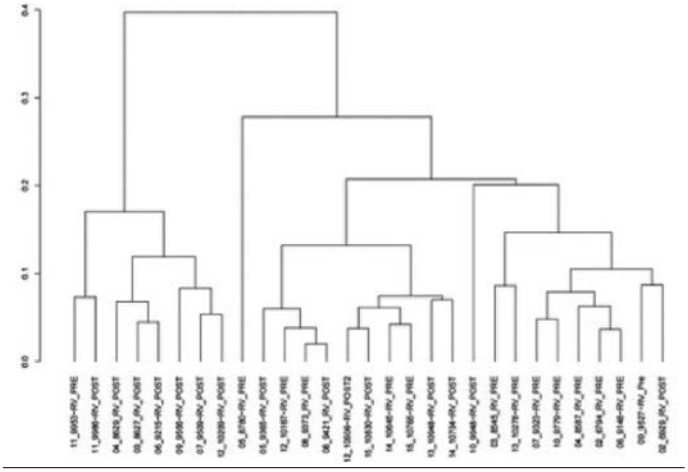

Figure 1.

Summary/Conclusions: In ITPc patients, ETP can induce overexpression of genes involved in platelet activation and megakaryopoiesis and also alter key/relevant/important-signaling pathways such as JAK/STAT and PI3K/Akt.

P362

DEFECTIVE PTEN REGULATION CONTRIBUTES TO B CELL HYPERRESPONSIVENESS IN CHRONIC IMMUNE THROMBOCYTOPENIA

S. Wang[1,*], Y. Guan[1], H. Li[1], R. Yang[1], Y. Wang[2]
[1]State Key Laboratory of Experimental Hematology, Institute of Hematology and Blood Disease Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China, Tianjin, [2]Second Affiliated Hospital of Kunming medical University, Kunming, China

Background: Immune thrombocytopenia (ITP) is a complex autoimmune disease characterized by low platelet counts. The autoantibodies produced by autoreactive B cells against self-antigens, specifically immunoglobulin G (IgG)

antibodies against glycoprotein IIb (GPIIb)/IIIa and/or GPIb/IX, are considered to play a crucial role. B cell homeostasis and function are controlled by cell surface receptor-ligand interactions. The activation of PI3K is initiated by engagement of the pre-B cell receptor (BCR) and the BCR. The phosphatase and tensin homolog (PTEN) suppress the activity of the PI3K pathway. As a consequence, loss of PTEN function leads to excessive PI (3, 4, 5) P 3 at the plasma membrane and to recruitment and activation of Akt family members that potently drive cell survival and proliferation .PTEN regulates normal signaling through the B cell receptor (BCR). In immune thrombocytopenia (ITP), enhanced BCR signaling contributes to increased B cell activity, but the role of PTEN in human ITP has remained unclear. Both IL-21/IL-21R signaling and PI3K-PTEN molecules are involved in maintaining normal humoral immunity and deletion of autoreactive B cells. In this study, we want to determine whether abnormalities in PTEN might contribute to increase B cell responsiveness in this disease and IL-21 mediated PTEN induction was defective. Meanwhile, we want to evaluate the relation between the expression of PTEN in B cells and the prognosis of ITP, which will provide a theoretical basis of new treatment strategy for the ITP patient.

Aims: PTEN is involved in maintaining normal B cell function. Since B cell overactivity is characteristic ofImmune thrombocytopenia(ITP) we sought to determine whether abnormalities in PTEN might contribute to increase B cell responsiveness in this disease.

Methods: 1. This study recruited 28 newly-diagnosed CITP patients and 26 sex and age matched health volunteers as health controls(HC)Peripheral blood mononuclear cells were isolated from collected anti-coagulated blood. 2. Flow cytometry and real time quantitative PCR were used for detecting the level of PTEN from PBMC cells of HC and CITP patients. 3. The relationship between PTEN levels and the disease severity of CITP was analyzed. 4. PBMC cells were incubated with human rIL-2 rIL-21r CD40L or anti-IgM alone or in combination for 72h and after that the PTEN level was detected by flow cytometry .The proportion and surface activated marker of B cells were determined by flow cytometry

Results: 1. Compared to HC the expression of PTEN was diminished in each CITP B cell population except IgD-CD38low/-memory B cells. In addition PTEN mRNA was also decreased in ITP B cells. 2. The level of PTEN in B cells was slightly correlated with blood platelet count (p=0.008) and also directly correlated with the positive serum platelet-specific antibody (P=0.03). 3. The capacity of IL-21 to induce PTEN expression in B cells of HC was found by flow cytometry. Importantly.We found that CD40L and anti-IgM were the most potent inducers of PTEN expression in normal B cells, followed by IL-21 and IL-2. Neither IL-21 alone nor CD40L plus anti-IgM nor the three in combination stimulated PTEN protein up-regulation in B cells in CITP patients. 4. These immature B cells in CITP patients had a greater expression of CD95 but less PTEN compared to HC suggesting that down-regulation of PTEN was associated with an increasing proportion of immature B cells with a more activated phenotype in CITP patients (Figure 1).

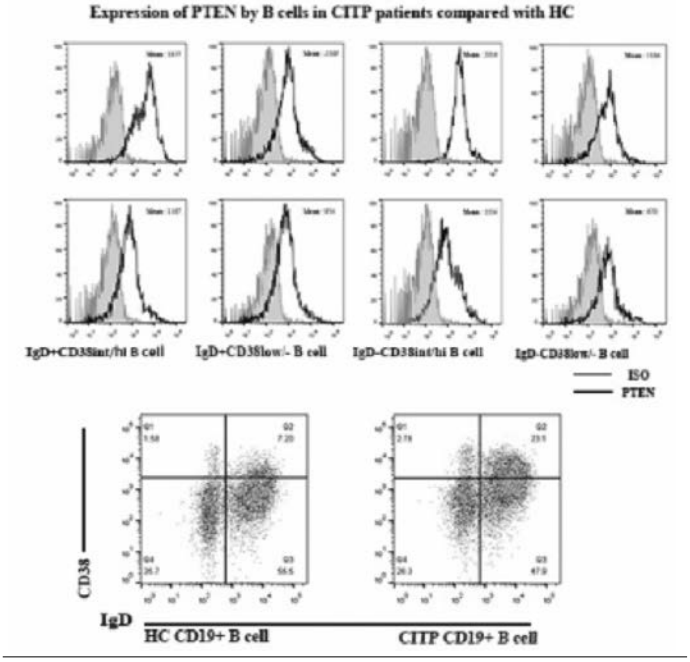

Figure 1.

Summary/Conclusions: Immune thrombocytopenia B cell showed decreased levels of PTEN and the decrease was associated with low platelet count and positive serum platelet-specific antibody.The capacity of IL-21 to induce PTEN was defect in CITP.Together,these data suggesting that the defective PTEN expression,regulation and function contribute to B cell hyper-responsiveness in CITP.

A DECREASED INTRACELLULAR S1P LEVEL AND S1P RECEPTORS EXPRESSED ON MEGAKARYOCYTES POSSIBLY CONTRIBUTE TO DEFECTIVE PROPLATELETS FORMATION IN IMMUNE THROMBOCYTOPENIA

J. Xue[1], J. Zhang[1], Q. Wang[1], L. Xu[1], X. Zhu[1], Y. He[1], Y. Kong[1], Y. Chang[1], X. Zhao[1], X. Zhao[1], M. Lv[1], L. Xu[1], K. Liu[1], X. Huang[1], X. Zhang[1,*]
[1]Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Immune thrombocytopenia (ITP) is a common autoimmune disorder characterized by increased bleeding tendency and isolated thrombocytopenia. The precise pathogenesis of the decreased thrombopoiesis in ITP remains unknown. It has been demonstrated that megakaryocytes (MKs) in ITP show impaired proplatelets formation (PPF) (Br J Haematol.2014;165:854-64). However, the pathogenesis of the impaired PPF in ITP is not entirely understood. Additionally, the lipid mediator sphingosine 1-phosphate (S1P) plays a critical role in megakaryocytic PPF in the bone marrow (BM) niche (J Exp Med. 2012;209:2137-40). It has been demonstrated that cell-surface S1P receptors (S1PR) on MKs trigger the activation of Gi/Rac GTPase signaling. Sphingosine kinase 2 (Sphk2) is the major isoenzyme regulating intracellular synthesis of S1P in MKs. Additionally, intracellular S1P influences the expression of Src family kinase (SFK) in MKs, including 6 members (Fyn, Lyn, Src, Yes, Fgr, and Hck), which mutually regulate each other with Rac GTPase.

Aims: To determine whether the S1P levels in both the BM niche and within MKs, as well as S1PR expression of MKs contribute to the defective thrombopoiesis in ITP through impaired PPF.

Methods: The PPF of ITP-MKs was measured by an *in vitro* PPF assay using HSCs from the BM. (FASEB J. 2010;24:4701-10). Additionally, all-trans-retinoic acid (ATRA), the S1pr1-specific agonist SEW2871, and extracellular S1P were used as interference factors. The concentration of S1P in the plasma and BM was analysed by ELISA. The concentration of intracellular S1P was measured using liquid chromatography mass spectrometry (LC/MS) analysis. Intracellular Sphk2 , SFKs and cell-surface S1PR were measured using PCR and western blotting. The location of Sphk2 was analysed by immunofluorescence using an anti-human Sphk2 antibody. The activities of Rac-GTP were quantified by pull-down assay.

Results: Significantly fewer numbers of proplatelet-forming MKs were observed in ITP cultures. The concentration of S1P in the plasma and in BM of patients with ITP was measured, of which the results showed no significant difference in the plasma/BM S1P ratio. Decreased expression of S1PR1 and S1PR4 was observed in ITP MKs. We found that downstream Gi/Rac GTPase signalling activated by S1PR1 was down-regulated. ITP-MKs exhibited decreased intracellular Sphk2, indicating less biosynthesis of intracellular S1P. Immunostaining of Sphk2 in ITP MKs was performed, showing that less Sphk2 was primarily localized to the nucleus of ITP MKs. Intracellular S1P of ITP MKs was further explored showing a decrease of megakaryocytic S1P production ascribed to significantly reduced Sphk2. Furthermore, the gene expression and protein levels of family of SFKs were examined in ITP MKs, and the overall mRNA expression was significantly limited in ITP MKs. The total Src protein levels and p-SFKs (phospho-tyrosine-418) were significantly reduced in ITP MKs, indicating significant reduction of SFK activity. ATRA, SEW2871 and extracellular S1P enhanced Rac GTPase activity and SFK expression, which rescued the defect of PPF in ITP.

Summary/Conclusions: Decreased intracellular S1P ascribed to significantly reduced Sphk2, results in down-regulated SFK expression and activity, and decreased S1PR1 and S1PR4 down-regulate Gi/Rac GTPase signalling in ITP-MKs. Therefore, abnormal S1P/S1PR possibly plays a role in the pathogenesis of impaired PPF in ITP, which may be therapeutically regulated by ATRA.

ANTIBODY MEDIATED GLYCAN MODIFICATION: A POTENTIAL ROLE IN PLATELET DESTRUCTION IN AUTOIMMUNE THROMBOCYTOPENIA

I. Marini[1,*], R. Jouni[1], J. Alex[2], A. Greinacher[2], T. Bakchoul[1]
[1]Center for Clinical Transfusion Medicine, University Hospital of Tübingen , Tübingen, [2]Transfusion Medicine , Universitätsmedizin Greifswald, Greifswald, Germany

Background: Immune thrombocytopenia (ITP) is a bleeding disease caused by autoantibodies (AAbs) directed against platelet (PLT) glycoproteins (GP). A novel mechanism of antibody-mediated PLT destruction based on Fc-independent PLT clearance via Ashwell-Morell receptors (AMRs), which recognize glycan modifications on the surface of PLTs, has been suggested in mice.

Aims: In this study we investigated the effects of human AAbs from ITP patients on the glycan pattern of human PLTs and the consequent impact on their survival *in vivo*.

Methods: Monoclonal platelet antigen capture assay (MAIPA) and lectin binding assay (LBA) were used to analyzed sera from ITP patients and healthy donors. In LBA, after incubation with sera and PLTs from healthy donors, the modification in glycan pattern was investigated by flow cytometry using lectins; Ricinus communis agglutinin (RCA), Erythrina cristagalli lectin (ECL) and Peanut agglu-

tinin (PNA) that bind to galactose, N-acetyllactosamine and N-acetylgalactosamine residues, respectively. The NOD/SCID mouse model was used to study the impact of different glycan patterns on the survival of human PLTs.
Results: In this work 37 sera from ITP patients and 25 sera from healthy donors were analyzed. In the LBA, after incubation with AAbs, different patterns of glycan modification were observed. 17/37 sera caused a significant increase in PNA binding compared to heathy donors: (median fold increase (FI): 1.21, range: 1.08 – 1.40). 9/37 sera induced higher ECL binding (median FI: 1.02, range: 1.08 – 1.15). In contrast, 8/37 sera showed strong decrease in RCA binding (median FI: 0.52, range: 0.50 – 0.59). Sera from healthy donors did not induced significant change. Interestingly, not only GP-Ib/IX AAbs but also GPIIb/IIIa AAbs were able to modify glycan pattern. In NOD/SCID mice the administration of AAbs induced an accelerated clearance of human PLTs from the circulation. The destruction of human PLTs by ITP-AAbs was decreased but not completely prevented by a specific neuraminidase inhibitor that blocks glycan changes on PLT surface (survival of human PLTs after 5h: 48%, range 41-53% *vs* 29%, range 22-40%).
Summary/Conclusions: Our results demonstrate that AAbs from ITP patients are able to induce cleavage of glycan moieties on the PLT surface in distinct manners. Antibody-mediated modification of glycan patterns seems to contribute to AAb-mediated PLT destruction.

Trambusti", University of Bari, [6]U.O.C of Pediatrics, Hospital "D. Camberlingo", Francavilla Fontana, Bari, Italy, [7]Instituto de Investigaciones Médicas Alfredo Lanari, Universidad de Buenos Aires, IDIM-CONICET, Buenos Aires, Argentina, [8]Department of Medical Sciences, University of Trieste, Trieste, Italy

Background: Familial platelet disorder with propensity to acute myeloid leukemia (FPD/AML) is a rare autosomal dominant inherited thrombocytopenia (IT) caused by mutations in the hematopoietic transcription factor RUNX1; an important hallmark of this IT is the increased risk of developing myeloid neoplasms, such as AML and myelodysplastic syndromes (MDS). FPD/AML is caused by different mutations of *RUNX1* encoding the DNA binding subunit (known as core binding factor-alpha, CBF-alpha) of the CBF transcription complex. The N-terminus domain of RUNX1 (runt-homologous domain) mediates DNA binding and heterodimerization to CBF-beta, the other subunit of the CBF complex. The C-terminus of RUNX1 includes domains that are involved in transcription activation and repression. This IT is characterized by impaired megakaryopoiesis and moderate thrombocytopenia, with normal-sized and dysfunctional platelets.
Aims: To unravel the molecular basis of ITs and to improve our knowledge on the molecular basis and clinical-laboratory picture of FPD/AML.
Methods: Whole exome sequencing (WES) was performed in 86 propositi with an unknown IT after the diagnostic workup based on the most updated diagnostic algorithm for ITs (Clin Genet 2016;89:141). *RUNX1* variants detected by WES were confirmed by Sanger sequencing in the propositi and all available family members, which also undergo clinical-laboratory characterization. The study was approved by the Institutional Review Board of the IRCCS Policlinico S. Matteo Foundation; all patients gave written informed consent.
Results: We identified three pedigrees (families 1-3) with different *RUNX1* heterozygous mutations, all segregating with thrombocytopenia in the respective families: the novel variants c.578T>A and c.967+2_5del, and the known c.351+1G>A. The thirteen individuals carrying the *RUNX1* mutations had mild thrombocytopenia (platelet count ranging from 70 to 130 x 10^9/L) with mild bleeding tendency. Platelet sizes were within the normal range in all the six patients analyzed, and the serum level of thrombopoietin was normal or moderately increased. No specific morphological alteration of platelets was detected, except for moderate reduction in the alpha-granule content in family 1, confirmed by immunofluorescence analysis. The surface expression of the major platelet glycoprotein (GP) complexes GPIIb-IIIa and GPIb-IX-V was normal. In family 1 a moderate reduction of GPIa-IIa was detected, regardless of genotypes at the *ITGA2* locus. A defective aggregation was detected after platelet stimulation with collagen 4 mcg/ml and ADP 2 mcM in the five patients investigated; normal responses were obtained using collagen 20 mcg/mL, ADP 20 mcM and ristocetin 1.5 mg/mL, suggesting mild functional platelets defects. Of note, three patients from two families developed AML, with a prevalence lower than reported in literature, probably because of a different criteria of enrolment (*RUNX1* germline mutations are usually searched in ITs associated with AML). No solid/hematological cancer was reported in family 1.
Summary/Conclusions: FPD/AML is an IT lacking pathognomonic laboratory criteria: it is characterized by a mild functional defect and, much more importantly, by a normal platelet size, similarly to the other ITs predisposing to hematological malignancies (*ANKRD26* and *ETV6*-related thrombocytopenias). Given the importance of recognizing these diseases for patients counseling, follow-up, and therapeutic approach, we recommend a systematic screening for *RUNX1*, *ANKRD26*, and *ETV6* mutations in all patients with an autosomal dominant IT and normal platelet size.

A SINGLE-ARM, OPEN-LABEL, LONG-TERM EFFICACY AND SAFETY STUDY OF SUBCUTANEOUS ROMIPLOSTIM IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA

J. Grainger[1,*], J. Bussel[2], N. Cooper[3], M. Tarantino[4], V. Blanchette[5], J. Despotovic[6], A. Maschan[7], N. Carpenter[8], M. Eisen[9], B. Mehta[9]
[1]University of Manchester, Manchester, United Kingdom, [2]Weill Cornell Medicine, New York, United States, [3]Hammersmith Hospital, Imperial College, London, United Kingdom, [4]The Bleeding and Clotting Disorders Institute, Peoria, United States, [5]Hospital for Sick Children, Toronto, Canada, [6]Texas Children's Hematology Center, Houston, United States, [7]Federal Research Center of Pediatric Hematology, Oncology and Immunology n.a. Dmitry Rogachev, Moscow, Russian Federation, [8]Amgen Ltd., Uxbridge, United Kingdom, [9]Amgen Inc., Thousand Oaks, United States

Background: The use of romiplostim in children with ITP has been evaluated in phase 1/2 and 3 studies. Here we describe children with ITP who will receive open-label SC romiplostim for up to 3 years (y).
Aims: To assess platelet responses in children with ITP receiving romiplostim.
Methods: Eligible children, recruited in 16 countries worldwide, had ITP for ≥6 months, ≥1 prior ITP therapy, and platelet (plt) counts ≤30×10^9/L. Weekly SC dosing started at 1 µg/kg and was titrated in 1 µg/kg increments up to 10 µg/kg to target plt counts of 50-200×10^9/L. The primary endpoint was the% of time in the first 6 months with a plt response (plt count ≥50×10^9/L without rescue medication use in the past 4 weeks).

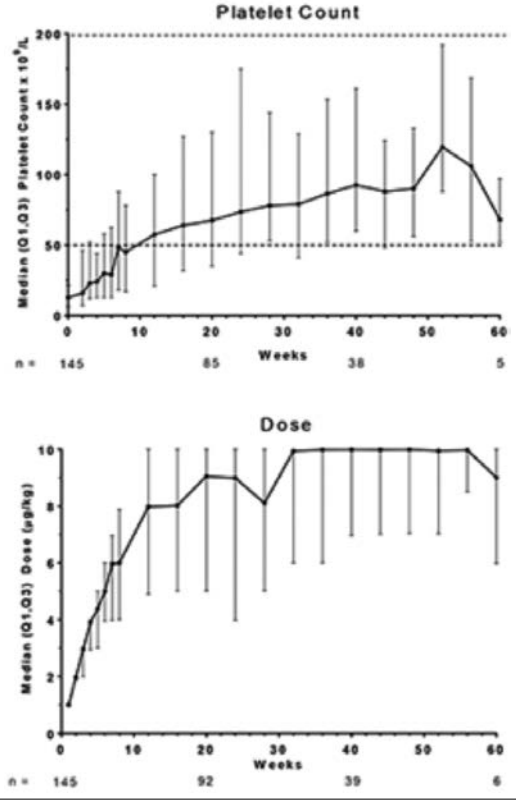

Figure 1.

Results: As of 15 Mar 2016, 145 patients received ≥1 dose. At baseline, median (min-max) age was 10 (2-17) y; 51% were female; 4% had prior splenectomy. Median (min-max) ITP duration was 1.9 (0.5-12.3) y and plt count was 13 (2-168)×10^9/L. The median (Q1, Q3)% of time with a plt response in the

first 6 months was 50% (0%, 83.3%); that of months 7-12 was 92% (33%, 100%). Overall, 80% (114/143) of patients had a plt response. The median (Q1, Q3)% of time with an increase in plt counts ≥20×10^9/L above baseline was 60% (25%, 84%). The median dose increased to 10 µg/kg by week 32. Median (min-max) treatment duration to date was 25 (1-67) weeks for a total exposure to date of 79 patient-years. Median (min-max) average weekly romiplostim dose over the course of the study was 6.1 (0.4-9.0) µg/kg. 32 patients (22%) discontinued treatment for lack of efficacy (n=17), required other therapy (n=5), patient request (n=4), noncompliance (n=2), adverse event (AE) (n=2) (interstitial lung disease in a 15 y old boy and abdominal pain, vomiting, and headache related to treatment per investigator in a 9 y old girl), administrative decision (n=1), and investigator decision (n=1). 34 (23%) patients received rescue medications. 15 (10.3%) patients had serious AEs (SAEs) including epistaxis (n=4), petechiae (n=2), decreased plt count (n=2), and thrombocytopenia (n=2). A case of abdominal pain was the only SAE deemed treatment-related by the investigator. CTCAE grade 3 bleeding was seen in 8 patients (6%) and included epistaxis (n=5), ecchymosis (n=2), petechiae (n=2), and 1 case each of hematemesis, hematoma, SC hemorrhage, injection site hemorrhage, and mouth hemorrhage. No grade 4 or 5 bleeding was observed. No neutralizing antibodies against romiplostim or TPO were identified. Of 30 patients with baseline bone marrow biopsies (bone marrow biopsies were obtained at European sites), all had modified Bauermeister scores of grade 0 (no reticulin) or 1 (fine fibers) and bone marrows typical for ITP. Of these 30 patients, 21 had evaluable on-study biopsies obtained after ~1 year of treatment, with no increases in 2 or more grades, findings of collagen, or bone marrow abnormalities (Figure 1).

Summary/Conclusions:
In this year 1 datacut of an ongoing open-label study of romiplostim in children with ITP, the% of time in the first 6 months with a platelet response was 50%, with 80% of children having a platelet response at some point on study. The median romiplostim dose reached 10 µg/kg and there were no new safety signals. No effects of romiplostim were observed on the bone marrow in the subset of patients with bone marrow biopsies. Future datacuts for years 2 and 3 in this study, the largest of romiplostim in children with ITP with 79 patient-years of exposure to date, will provide more information on platelet response, dose requirements, and safety.

P368

NOVEL THIENOPYRIDINES AS POTENT PLATELET INHIBITORS: FUTURE TREATMENTS FOR PLATELET HYPERACTIVITY DISORDERS?

N. Binsaleh[1,*], C. Wigley[1], K. Whitehead[1], D. Moreno-Martinez[1], S. Daniels[1], S. Jones[1], M. van Rensburg[2], L. Pilkington[2], D. Barker[2], N. Dempsey-Hibbert[1]
[1]School of Healthcare Science, Manchester Metropolitan University, Manchester, United Kingdom, [2]School of Chemical Sciences, University of Auckland, Auckland, New Zealand

Background: Platelet hyperactivity is associated with a number of disorders including Acute Coronary Syndromes (ACS) and manifests as increased platelet activation and often inappropriate thrombus formation. The thienopyridine class of anti-platelet drugs, of which clopidogrel and prasurgrel are the most well known, target the $P2Y_{12}$ receptor on platelets, blocking the effects of the platelet agonist ADP. However, the effect of these drugs is variable amongst patients, with some patients responding well and some remaining at risk of thrombosis. This variability highlights a need for a refinement of this class of $P2Y_{12}$ inhibitor.
Aims: The aim of this study was to assess the efficacy of six novel thienopyridine derivatives synthesized by our group by examining their potential as *in-vitro* inhibitors of platelet function.
Methods: Healthy human platelets were isolated and incubated with novel thienopyridine compounds (DJ0081, DJ0199, DJ0021, DJ0206, DJ0171, DJ0097) (10µM, 30min) prior to stimulation with ADP (10µM) and analysis of alpha granule secretion (CD62P expression), GPIIbIIIa activation (PAC1 expression) and platelet leukocyte aggregate (PLA) formation using flow cytometry. Furthermore, light transmission aggregometry (LTA) was used to assess ADP-stimulated aggregation after these treatments. As clopidogrel is usually prescribed in combination with the COX-1 inhibitor acetylsalicylic acid (ASA), synergy of the novel compounds with ASA (30µM) was also analysed by LTA. All results were compared to ADP-stimulated samples and samples treated with clopidogrel (10µM, 30min) prior to ADP stimulation.
Results: All six novel compounds demonstrated a significant reduction in ADP-mediated platelet aggregation (P<0.001), CD62P expression (p<0.001), PAC1 expression (p<0.01) and PLA formation (p<0.05). These compounds were also shown to enhance the inhibitory effects of ASA. DJ0171 and DJ0199 were particularly potent, displaying greater inhibitory effect than clopidogrel.
Summary/Conclusions: The study demonstrates the potential for new thienopyridine compounds as modulators of platelet function and points to the possibility of future use in patients at risk of platelet hyperactivity and thrombosis.

PATIENT-REPORTED OUTCOMES AND HEALTHCARE RESOURCE UTILIZATION BEFORE AND DURING TREATMENT WITH ECULIZUMAB: RESULTS FROM THE INTERNATIONAL PAROXYSMAL NOCTURNAL HEMOGLOBINURIA REGISTRY

P. Muus[1,*], S. Langemeijer[1], B. Höchsmann[2], A. Hill[3], L. Arnold[3], G. Tjønnfjord[4], B. Donato[5], P. Gustovic[6], A. Wilson[5], J. Szer[7]
[1]Radboud University Medical Center, Nijmegen, Netherlands, [2]Institute for Clinical Transfusion Medicine and Immunogenetics, University Hospital Ulm, Ulm, Germany, [3]St. James's University Hospital, Leeds, United Kingdom, [4]Oslo University Hospital, Oslo, Norway, [5]Alexion Pharmaceuticals, Inc., Lexington, MA, United States, [6]Alexion Pharma GmbH, Zurich, Switzerland, [7]Royal Melbourne Hospital and University of Melbourne, Melbourne, Australia

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare disease caused by somatic phosphatidylinositol glycan class A (*PIGA)* gene mutation in bone marrow stem cells. Clinical manifestations may include fatigue, abdominal pain, dyspnea, dysphagia, erectile dysfunction, anemia, sudden hemoglobin level reductions due to complement-induced hemolysis, and PNH-related complications such as thrombosis, chronic kidney disease, and pulmonary hypertension, all of which impair quality of life (QoL) and could impact survival. Eculizumab, a humanized monoclonal antibody approved for treatment of PNH, reduces intravascular hemolysis, thrombosis rates, and other PNH-associated comorbidities. The International PNH Registry (NCT01374360) is an ongoing prospective, multinational, observational study established to record the natural history of patients with PNH and collect data on long-term efficacy and safety of eculizumab treatment.
Aims: Analyze patient-reported outcomes (PRO) and healthcare resource utilization (HRU) before and during eculizumab treatment.
Methods: Patient assessment questionnaire (PAQ) data for patients with PNH who commenced eculizumab after Registry enrollment and had data available as of August 1, 2016, were analyzed. Patients had to have non-missing data on demographics, ≥1 recorded PAQ within 12 months prior to eculizumab initiation, and ≥1 PAQ recorded ≥6 months after initiation. Outcomes of interest included changes in QoL assessments (Functional Assessment of Chronic Illness Therapy [FACIT]-Fatigue score; EORTC QLQ-C30 score, disease symptoms, Karnofsky Performance scale, HRU, and missed work days.
Results: Of 4082 enrolled patients, 649 had non-missing data on demographics and initiated treatment with eculizumab as of August 1, 2016; 229 patients (55% female; 86% white; 74% from Europe) of the 649 met inclusion criteria for the current analysis. Median (min, max) interval between PNH disease start and initiation of treatment was 4.4 (0.1, 44.9) years. Clinically meaningful improvement in FACIT-Fatigue score (≥4-point increase) was reported by 53% of patients after initiating eculizumab (mean change, 5.2 points, Figure 1). Clinically meaningful improvement (≥10-point increase) was also observed in EORTC QLQ-C30 mean scores for global health/QoL (mean change, 15.1), role functioning (16.3), emotional functioning (12.1), and social functioning (13.9) subscales. PNH-related symptoms disappeared in 19–44% of patients who reported the symptom prior to eculizumab across all assessed symptoms except erectile dysfunction, which did not disappear in any of the 21 patients who answered this question both before initiation and during eculizumab treatment. Mean Karnofsky scale scores improved by 8.4 points after eculizumab initiation. HRU decreased for emergency room visits and number of missed work days while patients received eculizumab (incidence rate ratio [IRR] [95% confidence interval (CI)], 0.33 [0.20, 0.54] and 0.48 [0.25, 0.93], respectively) and increased for healthcare provider visits and hospital admissions (IRR [95% CI], 1.47 [1.22, 1.77] and 1.17 [0.60, 2.27], respectively).

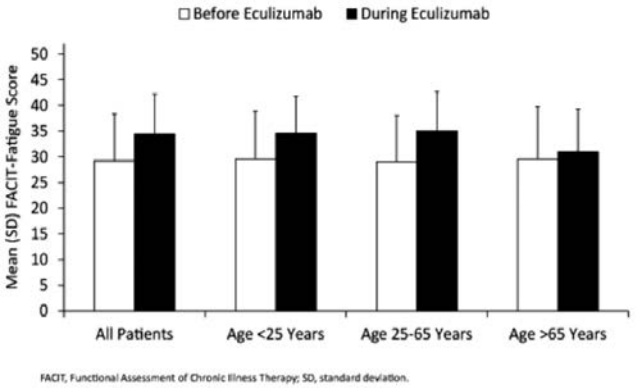

Figure 1.

Summary/Conclusions: In this cohort of patients from the International PNH Registry, treatment with eculizumab was associated with clinically meaningful improvements in PROs, including assessments of fatigue, global health status, patient functioning, and disease-related symptoms, as well as a decrease in emergency room visits and number of missed work days.

P370

ECONOMIC IMPACT OF INTRODUCING AGE-ADJUSTED D-DIMER CUT-OFF LEVELS IN THE DIAGNOSIS STRATEGY OF VENOUS THROMBOEMBOLISM

P. Toulon[1,*], N. De Pooter[2], M. Brionne-François[3], M. Smahi[4], L. Abecassis[5]
[1]Hematology, Pasteur University Hospital, Nice, [2]Hematology, General Hospital, Grasse, [3]Hematology, University Hospital, Caen, [4]Hematology, Simone Veil Hospital, Eaubonne, [5]Hematology, General Hospital, Aulnay, France

Background: The diagnosis of venous thromboembolism (VTE) can be safely excluded in the case of D-dimer levels below a well defined cut-off level in patients with a low or intermediate pre-test probability (PTP), as the test negative predictive value (NPV) is close to 100%. As ageing is associated with increased D-dimer levels, the question arose whether D-dimer measurement was useful to rule out VTE in elderly patients.
Aims: The aim of the present study was to evaluate the clinical performance of a diagnosis strategy based on age-adjusted cut-off values calculated by multiplying the patient's age by 10 in patients aged over 50, and to evaluate its economic impact.
Methods: We included 1255 consecutive outpatients with non-high PTP of VTE referred to the emergency departments at 5 French centres (2 university hospitals, and 3 general hospitals, in whom D-dimer testing was prescribed. The same standardized procedure was used in the 5 centres *i.e.* D-dimer measurement in patients with a non-high PTP, and imaging techniques (usually computed pulmonary angiography in case of suspected PE and Doppler ultrasonography in case of suspected DVT) in the case of D-dimer above the cut-off level. D-dimer levels were evaluated using the same fully automated latex-based assay (HemosIL D-dimer HS500, Instrumentation Laboratory), the usual cut-off level for VTE exclusion being 500 ng/mL (fibrinogen equivalent units, FEU).
Results: VTE diagnosis was established by objective testing in 115 patients (9.2%): 88 of the 1082 patients referred for suspected PE (8.1%) and 27 of the 173 patents referred for suspected DVT (15.6%). D-dimer levels were above 500 ng/mL in all patients with VTE and in 521 of the 1140 patients without VTE (45.7%), leading to test NPV and sensitivity of 100%. The overall test specificity was 54.3%, even though it significantly decreased in an age-dependent manner over 60 years old. This is due to increased D-dimer levels in older patients particularly in those above 80 years. Using age-adjusted cut-off levels, calculated by multiplying the patient's age by 10, significantly improved the overall test specificity (60.2%). The NPV remained high (99.9%), even though a 78 y-old female with a low PTP of PE would have been misdiagnosed as her D-dimer level (540 ng/mL) was above 500 ng/mL but below the age-adjusted cut-off value. Such an improvement in test performance was found both in patients with suspected PE and DVT (Table). As such an increase in test specificity would have led to exclude VTE in a higher percentage of patients in the studied population, we evaluated the cost-effectiveness of both strategies, taking into account the local reimbursement rates of D-dimer testing, angiography and Doppler ultrasonography (16.20, 58.72, and 75.60 Euros respectively). The economic impact of the proposed diagnosis strategy was a decreased of 6.9% of total costs (45,023.4 *vs* 48,356.4 Euros) for PE diagnosis and 5.1% (9,909 *vs* 10,438.2 Euros) for DVT. If such an analysis was used in the US, where angiography and Doppler US were more expensive (648 and 226 US$ respectively), and D-dimer less costly (14 US$), the cost savings would have been even higher (-11.0% for PE, and -6.3% for DVT).
Summary/Conclusions: The use of age-adjusted cut-off levels for D-dimer, in patients aged over 50 years old, led to a significant increase in the test specificity, but correlatively to slightly decreased NPV and sensitivity. Even though some patients with D-dimer levels above 500 ng/mL but below the age-adjusted cut-off value could be misdiagnosed, such a strategy was found to be safe in our studied population with a high NPV (99.9%) and sensitivity (99.1%), and cost-effective.

P371

IMPACT OF CELLULAR THERAPY ON THE ECONOMIC BURDEN AND SURVIVAL FOLLOWING RELAPSE AFTER HLA IDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ACUTE LEUKEMIA AND MYELODYSPLASTIC SYNDROME

S. Lachance[1,*], J. Bibeau[2], N. Ladjemil[3], J. Lachaine[4]
[1]Hematology, Hematopoietic cell transplantation, Université de Montréal, Hôpital Maisonneuve-Rosemont, [2]Peripharm Inc., [3]Peripharm, Montréal, [4]Pharmacie, Université de Montréal, Montreal, Canada

Background: Relapse following allogeneic hematopoietic stem cell transplant (aHSCT) is associated to a very poor outcome and remains an unmet medical needs. The impact of treatment approach on costs and survival remains unknown. The development of innovative cellular therapy for the treatment of relapse following aHSCT may change its dismal outcome but the cost of such intervention has prohibited its large-scale development.
Aims: The objective of this study was to measure the economic burden associated with the management of relapse following aHSCT and to evaluate the impact of treatment choice on survival and health care costs.
Methods: A retrospective medical chart review was conducted at Maisonneuve-Rosemont Hospital (HMR) after research and ethic committee approval. Patients were selected using the Hematopoietic Stem Cell Transplant (HSCT) program database. Eligible patients were diagnosed with acute leukemia (AL) or MDS and relapsed following a HLA identical aHSCT between January 1st 2011 and December 31st 2014. Patients' and disease characteristics and relapse-related health care resource utilization were collected from the date of post transplant relapse until death or last follow-up. Canadian unit costs for each intervention/treatment were obtained from literature and governmental publications.
Results: During the study period, 645 HSCT were performed at HMR, 303 were allogeneic. A total of 36 patients met the inclusion criteria and were included in the analysis. 32 recipients were diagnosed with AL and 4 with MDS. Treatment approaches following aHSCT relapse were divided in three groups according to patient and physician choices: group 1 received supportive care (n=9), group 2 received chemotherapy or tyrosine kinase inhibitors (n=21) and group 3 received a cellular based therapy, either donor lymphocyte infusion (DLI) or a second aHSCT (n=6). The mean cost of care per patient per month was C$20,239 (SD=17,079). The median survival following relapse for the entire cohort was 12.4 months (SD=2.8). For group 1, 2 and 3, the mean cost of care per patient per month was C$17,436 (SD=16,447), C$22,914 (SD=18,474) and C$15,082 (SD=12,954), respectively. The median survival was 4.0 months (SD=2.0), 7.2 months (SD=1.6), and 44.6 months (SD=8.4), for treatment group 1,2 and 3 respectively (Figure1).

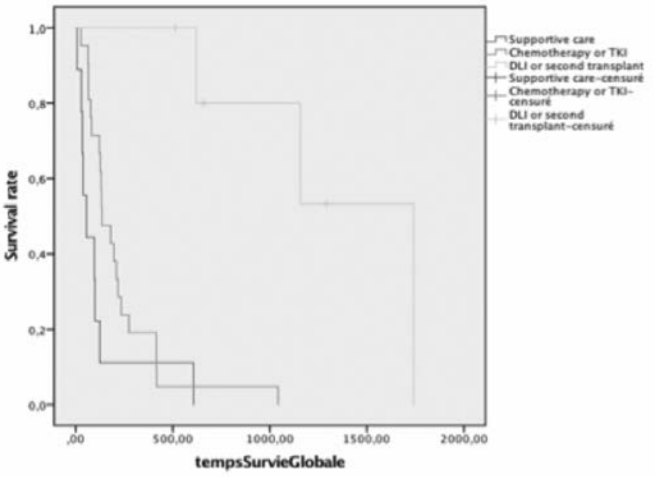

Figure 1. Survival according to treatment group.

Summary/Conclusions: Relapse following AHSCT is associated to a poor prognosis and survival and to significant use of health care resources. Despite the selection bias, only patients who received cellular based therapy, either DLI or another HSCT, enjoyed a prolonged survival. Healthcare resources devoted to the care of patients in relapse post AHSCT provide a comparative basis for cost efficiency analysis in the development of innovative cellular therapy.

P372

ACUTE MYELOID LEUKEMIA TREATMENT PRACTICE PATTERNS, HEALTHCARE RESOURCE UTILIZATION (HRU) AND COSTS IN A US COMMERCIALLY-INSURED POPULATION

M. Hagiwara[1,*], A. Sharma[1], K. Chung[2], T. E. Delea[1]
[1]Policy Analysis Inc., Brookline, MA, [2]Jazz Pharmaceuticals, Palo Alto, CA, United States

Background: AML is a rapidly progressive hematologic malignancy that accounts for 25% of adult leukemias in the Western world, with an estimated 5-year survival of 26%, and is associated with high HRU and costs.
Aims: To estimate HRU and costs among newly-diagnosed AML patients (pts) in a US commercially insured population by receipt of chemotherapy (CT) or stem cell transplant (SCT).
Methods: This was a retrospective observational study using the PharMetrics Plus® database. Pts were adults with AML (ICD-9-CM code 205.0x and corresponding ICD-10-CM codes) diagnosed between Jan 2007 and Jun 2016 (study period). Pts were excluded if: first AML claim was for remission/relapse;

not continuously enrolled for 12-months (mos) before the first AML claim (index date); evidence of acute promyelocytic leukemia anytime during the study period; missing enrollment information; or ≥1 hospitalizations during follow-up (FU) with missing cost. Pts were classified as treated or untreated, with treatment defined based on receipt of CT (inpatient or outpatient) or SCT. For treated pts, FU was partitioned into 2 periods: index date to 6 mos and >6 mos post index date. Mean HRU and costs over the FU period were calculated by receipt of treatment and, for treated pts, by time since index date.
Results: 10,197 pts met study criteria including 6,862 treated pts (67%) and 3,335 untreated pts (33%). Mean age was 55 and 60 years in treated and untreated pts, respectively. Mean follow-up was 19.3 mos in treated pts and 18.1 mos in untreated pts. Mean total costs were higher for treated pts ($386,711) *vs* untreated pts ($83,274). In treated pts, mean total costs were $166,156 during the first 6 mos (mean duration 3.9 mos), and $220, 555 during the remaining follow-up period (mean duration 19 mos). 26% of treated pts had SCT. Costs of inpatient and outpatient CT during the first 6 mos were $86,188, representing 22% of the total cost for treated pts (Table 1).

Table 1.

	Treated Pts			Untreated Pts
	All (n = 6,862)	Index date to 6 mos (n = 6,862)	6 mos post index date onward (n = 5,627)	All (n = 3,335)
SCT / RBC transfusions / platelet transfusions / GCSF, %	26.5 / 57.0 / 38.7 / 39.8	8.4 / 43.8 / 26.3 / 22.9	22.8 / 40.1 / 25.9 / 31.4	0.0 / 18.2 / 7.8 / 2.9
Office or outpatient visits, mean	108	36	72	39
Outpatient pharmacy claims, mean	72	16	56	46
Emergency department visits, mean	1.7	0.6	1.0	1.1
Hospitalizations, mean	3.6	1.6	2.0	1.1
Inpatient days, mean	49	25	24	11
Total costs, mean, $	386,711	166,156	220,555	83,274
SCT	54,526	16,699	37,827	0
Inpatient CT	102,999	67,849	35,150	0
Outpatient CT	35,827	18,339	17,488	0
Other inpatient	70,362	26,605	43,758	38,024
Other outpatient	102,058	31,939	70,119	21,816
Pharmacy	20,938	4,725	16,213	23,434

Summary/Conclusions: HRU and costs of managing AML pts are considerable, with greatest HRU and cost in pts receiving CT or SCT.

P373

HEALTH-RELATED QUALITY OF LIFE IN AL AMYLOIDOSIS PATIENTS WITH NERVOUS SYSTEM INVOLVEMENT

M. Yokota[1], S.D. Guthrie[2], T.P. Quock[2], K.L. McCausland[1,*], M.K. White[1], M. Bayliss[1]
[1]Optum, Lincoln, [2]Prothena Biosciences Inc, South San Francisco, United States

Background: In light chain (AL) amyloidosis, misfolded light chains accumulate and cause progressive peripheral neuropathy (PN) and failure of critical organs such as the heart and kidneys. Consequently, a progressive, ascending sensorimotor neuropathy is often a related clinical finding.
Aims: This study describes disease characteristics and health-related quality of life (HRQoL) in AL amyloidosis patients with peripheral nerve involvement (AL-PN).
Methods: An online survey was administered to AL-PN (n=126) and non-nerve–affected (n=215) patients to assess patient characteristics and HRQoL (based on the SF-36v2® Health Survey [SF-36v2]). The survey measures eight domains including physical functioning (PF), role physical (RP) due to health-related physical limitations, bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role emotional (RE), mental health (MH), in addition to physical (PCS) and mental component summary (MCS) measures. Patient characteristics were compared using chi-square tests. Differences in symptomatic and HRQoL burden were tested with multivariable logistic and linear models, respectively. Differences in mean HRQoL between AL-PN and non-AL-PN patients were compared to established minimally important differences (MIDs).
Results: Compared to non-nerve–affected patients, greater proportions of AL-PN patients visited ≥6 doctors (42.1 *vs* 19.5%, p <0.001) and ≥6 specialists (24.6 *vs* 9.9%, p <0.001). AL-PN patients also had symptoms for ≥1 year prior to receiving a diagnosis (50.8 *vs* 39.1%, p=0.035), relative to non-nerve–affected patients. Nearly all AL-PN patients (97.6%) reported multi-system involvement. Gastrointestinal involvement was more prevalent in AL-PN patients *versus* non-AL-PN patients (68.3 *vs* 28.8%, p <0.001). There were greater odds of experiencing numbness (OR=4.23, 95% CI: 2.45–7.30, p <0.001) and fatigue (OR=3.09, 95% CI: 1.36–7.02, p <0.01) among AL-PN patients as compared to non-AL-PN patients, even after controlling for other types of organ involvement. Similar findings were observed for gastrointestinal symptoms, such as alternating bouts of constipation or diarrhea (OR=1.92, 95% CI: 1.12–3.34, p=0.019) and early satiety/feeling fullness in the stomach (OR=1.80, 95% CI: 1.03–3.16, p=0.04). With the exception of RE, MH, and MCS, there were significant differences in SF-36v2 scores among AL-PN patients as compared to non-AL-PN patients (p <0.05 for all). These significant differences also exceeded the thresholds for clinically meaningful differences between the two groups.
Summary/Conclusions: This study suggests that the burden of illness from AL amyloidosis may be greater for those with PN involvement *versus* those without. AL-PN patients also experienced more complicated journeys to diagnosis and significantly worse symptoms related to nervous systems and physical HRQoL. The SF36v2, a reliable and valid assessment of HRQoL in AL amyloidosis studies, was sensitive to differences in HRQoL between AL-PN and non-AL-PN patients. Future research should examine whether improvements in neuropathy symptoms following treatment subsequently lead to improvements in HRQoL among patients with AL-PN. These findings are helpful for patient-focused drug development and supportive treatments.

P374

ACCESS TO COMMUNITY CHEMOTHERAPY IMPROVES PATIENT QUALITY OF LIFE

R. Iredale[1,*], R. Pugh[2], C. Bygrave[3], H. Cosh[3], W. Ingram[3], J. Kell[3]
[1]Faculty of Life Sciences and Education, University of South Wales, Pontypridd, [2]Tenovus, [3]Haematology, University Hospital of Wales, Cardiff, United Kingdom

Background: Deciding how services for people with haematological cancers are to be delivered is going to be an important challenge in the coming years. Clinics have limited clinic capacity in terms of staff and bed space to cope with increased demand. In Wales many day units are already at capacity, overcrowded and have long waits for treatment. Ambulatory care, including diagnosis, observation, consultation, intervention, and rehabilitation, has the potential to improve the patient experience, if traditionally-based hospital services are moved into the community. We used a Mobile Unit – a 34-tonne articulated lorry which opens out to become a bespoke clinical space - to deliver treatments in a community setting to a range of haematology patients for a period of 12 months in South Wales.
Aims: We aimed to explore whether the administration of cytotoxic therapy on a Mobile Unit in a community setting for patients with haematological cancers could prove to be a safe and efficient alternative to hospital therapy, and in particular whether this model of service delivery would be acceptable to patients. Our target group was patients with myeloma, aiming for up to 20 a day once or twice a week.
Methods: The first drugs administered on the Mobile Unit were zoledronate infusions, followed by bortezomib. When twice weekly doses were required, patients collected an additional injection pack which they could self-administer in their own homes, thereby saving another trip into hospital. Immunoglobulin infusions, taking between 1-2 hours, were also administered. There was a consultant review clinic on board for patients receiving bortezomib which further reduced the numbers of hospital visits for patients and also a nurse-led Quality of Life clinic.
Results: In one year 548 treatments were administered on 91 days to a total of 54 individual patients. All 54 patients had a diagnosis of myeloma. 56% are female and 44% are male with an age range of 46 to 90 years of age, with 48% over 70 years of age. 37 patients are married and all but 4 classed themselves as White British. The greatest number of patients treated in a single day was 16. Patient experience was measured using self-administered questionnaires which 50 patients completed. 100% of patients thought it was convenient or extremely convenient having their treatment on a Mobile Unit. 98% felt safe having their treatment outside hospital and 92% said their experience was better than hospital. Patients could drive right up to the door of the Mobile Unit and the average time waiting from arrival to treatment chair was 2 minutes, with many people not having to wait at all. Uptake of the psychosocial support services was lower than expected with only 10 people opting for additional support. Any criticisms received focused on the locations we chose to site the Mobile Unit in relation to accessibility via public transport.
Summary/Conclusions: Treatment in the community alleviates the stress of treatment and with minimal waiting times it gives some patients the ability to maintain family life and where possible to continue to work. It is both feasible and acceptable to begin to ambulate many different sorts of treatments. The possibilities opening up for haematology include rituximab maintenance; community blood transfusions; delivering pentamidine for patients at risk of pneumocystis infection; late effects clinics for teenage and young adult cancer patients; and myeloproliferative neoplasm clinics, possibly near community pharmacies to facilitate dispensing medicines such as hydroxycarbamide.

P375

THE BUDGET IMPACT OF TREATMENT-FREE REMISSION FOR FIRST-LINE NILOTINIB OR GENERIC IMATINIB IN TREATING CHRONIC PHASE PHILADELPHIA-POSITIVE CHRONIC MYELOID LEUKEMIA

D. Tran[1], S. Brown[1], N. Goyert[1], P. Brandt[2,*], D. Grima[1]
[1]Cornerstone Research Institute, Burlington, Canada, [2]Global Value & Access, Novartis Pharmaceuticals Corporation, East Hanover, United States

Background: The 2013 European LeukemiaNet (ELN) guidelines recommend switching from first-line therapy as early as 6 months with poor molecular response (MR). They also recognize the possibility of treatment-free remission (TFR), requiring deep MR (MR^4 or $MR^{4.5}$). These emerging shifts in practice will dramatically change chronic myeloid leukemia (CML) treatment patterns. Occurring in parallel to this is the introduction of generic imatinib in Europe,

which will have a substantial price difference compared with nilotinib. However, given the possible changes in switching patterns and use of TFR, this price difference may not translate into a similar magnitude of difference in drug budget for first-line nilotinib *vs* imatinib due to better MR with nilotinib.
Aims: To estimate the budget impact for first-line nilotinib *vs* imatinib when considering generic imatinib pricing, early treatment-switching, and TFR.
Methods: A state transition model was developed to project the impact of ELN switching and TFR use on clinical outcomes and treatment costs. Analyses were run for 1000 patients with newly diagnosed CML, starting either nilotinib or imatinib, over a 5-year time horizon and using French drug pricing. It was assumed that all patients in the model would switch therapy (imatinib to nilotinib, and nilotinib to dasatinib) based on the failure criteria of the ELN guidelines. As such, ENESTnd trial data were re-analyzed to estimate switching based on MR. The model assumed that patients could enter first-line or second-line TFR after 36 months of continuous therapy where the last 12 months were at $MR^{4.5}$. Duration of first-line or second-line TFR was based on an extrapolation of ENESTfreedom and ENESTop treatment-free survival curves, respectively. Monthly drug costs were €2,952 for first-line nilotinib and €1,063 for generic imatinib, assuming a 50% discount to brand pricing.
Results: A greater number of patients in the first-line nilotinib arm remained on first-line therapy (690 *vs* 479 at 15 mos., and 542 *vs* 368 at 60 mos.); achieved $MR^{4.5}$ on first-line therapy (442 *vs* 248 by 60 mos.); entered TFR on first-line therapy (347 *vs* 183 by 60 mos.); entered TFR on either first- or second-line (494 *vs* 400 by 60 mos.); and was in any TFR at 60 months (293 *vs* 200). The incremental budget impact per patient for first-line nilotinib *vs* imatinib decreased each year from €16,482 in Year 1 to €377 in Year 5. Overall, the 64% lower drug acquisition costs per month of imatinib (€1,063) *vs* nilotinib (€2,952) provided only a 17% lower total budget impact over five years (€141,204 *vs* €170,002) per patient.
Summary/Conclusions: Results from the model considered more switching as per 2013 ELN guidelines, which resulted in greater and quicker switching than observed in ENESTnd. Overall, it was projected that compared with imatinib, patients who receive first-line nilotinib would have earlier and more sustained molecular response-requirements for TFR eligibility—and be subject to less treatment-switching. The model projected that less than 50% of patients would remain on first-line imatinib at 15 months. This would significantly reduce the budget benefits of a lower imatinib acquisition price. The budget impact between first-line imatinib and nilotinib would be further reduced by TFR, which occurred in the model more frequently in the nilotinib group. The superior efficacy of nilotinib and the associated differences in switching and TFR eligibility are predicted to substantially offset the lower unit cost for generic imatinib.

Nuestra Señora de La Candelaria, Santa Cruz de Tenerife, [8]Hematology Department, C.H. de Navarra, Pamplona, [9]Hematology Department, H.U. Vall d´Hebrón, Barcelona, [10]Hematology Department, H.U. Infanta Leonor, Madrid, [11]Hematology Department, IDIBELL, H. Dúran i Reynals, Barcelona, [12]Hematology Department, C.H. de Segovia, Segovia, [13]Hematology Department, H.U. Gregorio Marañón, Madrid, [14]Hematology Department, C.S. Parc Tauli, Barcelona, [15]Hematology Department, H. U. Central de Asturias, Oviedo, [16]Celgene S.L.U., Madrid, [17]Hematology Department, H.U. Doctor Peset , Valencia, Spain

Background: The Geriatric Assessment in Hematology (GAH) scale is a newly developed tool that is intended to be an ancillary questionnaire to better categorize older patients diagnosed with common hematological neoplasms for intensive treatment in routine clinical practice. It is a brief (<12 min) and easy instrument, which takes into account 8 dimensions of geriatric assessment that were initially dichotomized into 0 or 1. The GAH scale has recently been shown to be psychometrically valid, responsive to clinical change, and able to predict survival.
Aims: To determine the weights for each dimension of the GAH scale and the cut-off points for the scale to be used as a tool to predict treatment tolerability in older patients diagnosed with myelodysplastic syndrome / acute myeloblastic leukemia, multiple myeloma, or chronic lymphocytic leukemia.
Methods: This was a multicenter, retrospective, observational study conducted at 14 Spanish sites. Prior participants of the GAH study were given treatment within 3 months after having completed the GAH scale were eligible for inclusion after giving informed consent.
A logistic regression model and a full multiple linear regression model were calculated to determine the weights for each dimension to find out its contribution to the final score; the ROC curve analysis was used to calculate the cut-off points that defined three groups: "go-on" (low probability to develop toxicity regardless of intensive or attenuated therapy), "slow-go" (high probability to develop toxicity with intensive therapy but low probability with attenuated therapy), and "no-go" (high probability to develop toxicity regardless of therapy).
Results: A total of 108 patients (women, 53.7%; median age [IQR], 78 [73-83] years) out of 360 included in the main study were evaluated. During treatment administration, 61 (56.5%) patients developed treatment-related toxicities, requiring discontinuation/modification of the initial therapy. The coefficients for the dimensions are: 7 for number of drugs, -10 for gait speed, 2 for mood, 23 for activities of daily living, 6 for subjective health status, 27 for nutrition, -5 for mental status, and 1 for comorbidities. The sum of the GAH scale score, ranging from 0 to 66, plus a factor derived from the treatment intensity (34 points for intensive therapy or 0 for attenuated) leads to a maximum score of 100 points, with a cut-off point set at 47. Figure 1 shows the GAH scale score for treatment toxicity prediction and the classification of patients according to their score. Among the 97 (89.8%) patients that received intensive therapy, 26 patients were classified as go-on, 48 as slow-go, and 23 as no-go. The proportion of patients that developed toxicities for each group was 34.6%, 56.3%, and 78.3%, respectively with a statistically significant difference (*P*=0.002).

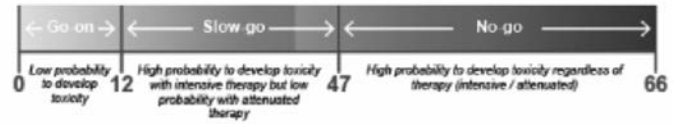

Figure 1.

Summary/Conclusions: The GAH scale appears to have the potential to give guidance for election of individual treatment regimens. By identifying elderly patients at high risk to develop toxicities, it may help to choose low-toxicity combinations, to avoid harmful therapies and to identify those patients that could benefit from more intensive treatment. Nonetheless prospective studies with larger populations should be performed to confirm these findings and to try to determine particular cut-off points for different diseases.

NUTRITIONAL NEEDS AND PREFERENCES OF MYELOPROLIFERATIVE NEOPLASM PATIENTS: PHASE IA OF THE NUTRIENT STUDY

R. Scherber[1,2,*], H. Geyer[3], A. Dueck[4], C. Johnston[5], B. Langlais[4], L. Padrnos[1], J. Palmer[1], A. Fleischman[6], R. Mesa[1]
[1]Hematology and Oncology, Mayo Clinic, Scottsdale, [2]Hematology and Oncology, Oregon Health and Science University, Portland, [3]Internal Medicine, [4]Biostatistics, Mayo Clinic, Scottsdale, [5]Arizona State University, Phoenix, [6]Hematology and Oncology, University of California, Irvine, Irvine, United States

Background: Cachexia, weight loss, and malnutrition in cancer patients are important contributors of adverse outcomes of cancer patients. MPN patients have abnormal cytokine expression (*e.g.*, IL-1, IL-6, IL-8, and TNF-a) that contributes to symptom burden (*e.g.*, fatigue, pruritus, night sweats, bone pain) and nutritional deficiencies (e,g., hypocholesterolemia, hypoalbuminemia, weight loss). Diets rich in fruits, vegetables, legumes, whole grains, fish, nuts, and low-fat dairy products are associated with a decrease in inflammatory (*e.g.*, TNF-a, IL-6, and CRP) and thrombotic markers (*e.g.*, homocysteine, fibrinogen; Chrysohoou 2004, Smidowicz 2015). To date, no studies have evaluated the nutritional needs or preferences of MPN patients in regards to dietary change.
Aims: The aim of this project was to determine the nutritional needs and preferences that will help inform the creation of a tailored MPN dietary intervention.
Methods: An internet-based survey was hosted by the Mayo Clinic Survey Research Center and promoted on multiple MPN-based forums, Facebook pages and websites during February of 2017. The survey included data on demographics, MPN characteristics, nutritional habits, supplement use, and symptom burden using the MPN-SAF TSS/MPN-10 (Emanuel 2012).
Results: *Demographics and symptom burden*: 919 international MPN patients responded to the online survey of which 22.5% were diagnosed with MF, 37.1% with PV, and 37.4% with ET. Respondents represented MPN patients from 37 countries, although the highest proportion of respondents were from the United States (48.8%), United Kingdom (32.7%), Australia (6%), and Canada (3.6%). Average MPN-SAF TSS score was 33.6 (SD=17). *Dietary Habits:* 22.5% of patients endorsed having food allergies or intolerances (Table 1). 31.4% of individuals followed a specific diet or had dietary restrictions. On average, MPN patients ate 2.1 meals outside the home per week. Among those taking supplements, 16.6% took supplements with the intent of reducing inflammation. Half (47.5%) of these individuals felt that the supplements they used made them feel better. Approximately 15% of respondents had tried alternative medicine to help treat their MPN. Among these, 44.8% were under the care of a naturopath and 60.2% endorsed that their treatment plan included dietary change. *Nutritional Education Preferences*: Overall, 34.4% of patients endorsed

using diet to help control their symptoms or MPN disease. Patients most often utilized books (28.2%), websites (27.1%), health care providers such as physicians, NPs or naturopaths (28.2%), online forums (23.2%), friends (12.2%), nutritionists(9.5%), phone or tablet applications (9.1%), or videos (4.2%) for nutritional education. The vast majority (95.9%) of MPN patients endorsed being willing to eat only certain foods if it helped to control symptom burden and or could help their MPN to stabilize or reduce the risk of their MPN getting worse (98.0%).

Table 1.

Frequency of dietary allergies, intolerances, restrictions and supplement use among a large international cohort of MPN patients (N=919).

Food Allergies and Intolerances	Frequency among all respondents
Milk	8.3%
Wheat	6.9%
Fruit	4.1%
Shellfish	2.8%
Soy	2.3%
Peanuts	1.7%
Egg	1.4%
Tree Nuts	1.4%
Fish	1.3%
Dietary Restrictions	
Low salt	6.6%
Gluten-free	6.5%
Mediterranean diet	6.0%
Vegetarian	5.7%
Low fat	5.3%
Anti-inflammatory	5.1%
Lactose intolerant	3.9%
Supplement Use	
Vitamin D	28.7%
Multivitamin/mineral	22.7%
Calcium	16.5%
Vitamin B12	13.8%
Curcumin	8.8%
CoQ 10	7.6%
Digestive enzymes	7.2%
Antioxidants	6.4%

Summary/Conclusions: There remains an unmet need for symptom burden improvement in low-risk MPN patients or among those who have reoccurrence of symptoms while on JAK inhibitor therapy. Nutritional interventions for MPN patients have not previously been investigated and have the potential to be paired with traditional interventions to allow MPN patients to self-manage symptom burden. This study represents the first evaluation of MPN-related nutritional habits and preferences. These results will be used to inform the creation of an MPN nutritional intervention with the goal of improving symptom burden and reducing inflammation.

P378

DO PHYSICIANS NEED HELP TO ADEQUATELY INFORM AND SUPPORT PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA? RESULTS FROM A QUALITATIVE STUDY IN GREECE

C. Karamanidou[1,*], A. Xochelli[1], V. Koutkias[1], P. Ghia[2], K. Stamatopoulos[1]
[1]Institute of Applied Biosciences, CERTH, Thessaloniki, Greece, [2]Division of Experimental Oncology and Department of Onco-Hematology, Università Vita-Salute San Raffaele and IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: Despite recent progress in prognostication and management, chronic lymphocytic leukemia (CLL) remains unpredictable at diagnosis, while virtually incurable, posing challenges to physicians on how to properly communicate the actual nature of the disease. Moreover, the great majority (~85%) of patients do not need treatment at diagnosis, creating a major cognitive dissonance between the perception of leukemia diagnosis and the "wait & watch" strategy usually applied, that may become a major reason of anxiety and quality of life (QoL) impairment for patients and frustration for physicians. Evidently, both patients and physicians need parameters that would allow co-decision making tailored to each particular case.
Aims: To identify physicians' needs in order to improve their communication skills and thus facilitate CLL patient empowerment through a patient-centeredness model.
Methods: An in-depth qualitative study with semi-structured interviews was conducted within hematologists (n=30) all over Greece. Data collection was considered as completed when saturation was reached *i.e.* no new themes emerged as assessed by the investigators. Content analysis was performed separately by a hematologist and a health psychologist with 98% inter-rater reliability score.
Results: None of the participants had ever received formal communication training but rather adopted the techniques of senior physicians or developed their own through experience alone, thus frequently doubting their approaches (n=12/30, 40%). The most popular communication technique mentioned was adaptation of the quality and quantity of information provided according to each patient's characteristics (n=29/30, 96.7%); followed by the use of caregivers as mediators for the communication of difficult issues (n=24/30, 80%); balance of realism and hope (n=21/30, 70%); careful choice of wording (*e.g.* lymphocytosis instead of leukemia) (n=18/30, 60%); gradual disclosure (n=17/30, 56.7%); and, descriptions through pictorial representations or metaphors (n=16/30, 53.3%). Even though physicians did not systematically assess patients' anxiety and depression levels, they often found themselves dealing with patients' emotions (n=29/30, 96.7%) through lengthy discussions. With regards to decision making, some mentioned that physicians should make all the decisions (n=9/30, 30%) and that patients are not always willing to take part in the decision-making process (n=8/30, 26.7%), while others were keener on stirring patients towards a decision (n=15/30, 50%), taking into account patients' preferences (n=10/30, 33.3%). Most physicians felt uncomfortable delivering bad news such as initial diagnosis, relapse and poor prognosis (n=25/30, 83.3%). Self-reported needs included (i) communication skills training (n=20/30, 66.7%); (ii) psychological support (n=7/30, 23.3%); and, (iii) working in a multidisciplinary team (n=8/30, 26.7%).
Summary/Conclusions: In the absence of structured communication guidance there is great uncertainty among physicians concerning their skills on communicating CLL nature and handling difficult situations, leading to distress endangering their engagement in a healthy relationship with the patient. Additional studies are warranted at European level for identifying physician needs in different countries aiming at improving their communication skills to support and empower CLL patients for participating in their own care and enhance their QoL.

Stem cell transplantation - Clinical 1

P379

OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR PATIENTS WITH ACUTE LEUKEMIA ABOVE 70 YEARS OF AGE: ON BEHALF OF THE ACUTE LEUKEMIA WORKING PARTY OF THE EBMT

O. Ringdén[1], A. Boumendil[2], M. Labopin[2], B. Sadeghi[1], B. Savani[3], M. Mohty[4], A. Nagler[5,*]
[1]LABMED, Translational Cell therapy Research, Karolinska Institutet, Stockholm, Sweden, [2]Hôpital Saint Antoine, Paris, France, [3]Division of Hematology/Oncology, Medical Center Drive, Nashville, United States, [4]Hôpital Saint Antoine, Paris, France, [5]Chaim Sheba Medical Center, , Tel-Hashomer, Israel

Background: The average age of patients (pts) with AML is about 67 years. Historically, many of these pts were not considered as viable candidates for allogeneic transplantation (HCT) because of concerns about increased transplantation-related toxicity and excessive non-relapse mortality (NRM), a challenging problem especially in older individuals. However the development of reduced-intensity conditioning (RIC) regimens and the improvement in HCT supporting care allowed the successful application of HCT in older pts with AML.
Aims: Compare outcome of allo SCT in acute myeloid leukemia AML patients aged above 70 years with that of younger patients.
Methods: AML patients aged between 50 and 90 years old receiving a first or second allo SCT between 2004 and 2014 with MSD or UD donor were included in the study. Comparison of outcomes of patients aged above 70 with that of patients between 50-70 years were performed for the whole group and separately according to disease status at SCT (CR1, CR2, above).
Results: Altogether N=16874 pts were included in the study, N=713 were aged above 70 years old (median 72, IQR 71-73) and N=16161 between 50 and 70 (median 59, IQR 55-63) . Older pts were more often male (62 *vs* 55%, p<0.001), had more often secondary AML (42% *vs* 28%, p<0.001), more advanced disease (42% *vs* 27%, p<0.001), more often peripheral blood stem cell grafts (96 *vs* 91%, p<0.001), more often unrelated donors (79% *vs* 59%, p<0.001) and poorer Karnofsky score (36% below 90 *vs* 29%, p<0.001), received more often reduced intensity conditioning (80 *vs* 63%, p<0.001). Incidence of acute GVHD II/IV, III/IV, chronic GVHD and relapse were the same in the two groups in multivariate analysis. Non-relapse mortality (NRM) at two years was 34% (95%CI 31%>38%) in pts above and 24% (25%>32%) in those below 70 years of age (p<0.001). Overall survival and leukemia-free survival (LFS) at 2 years was 38% (95%CI 34-42) *vs* 50% (95%CI 49-50) p<0.001 and 33% (95%CI 29-37) *vs* 44% (95%CI 43-45) in the two groups, respectively (p<0.001). Among pts in CR1, 2 years survival was 43%(95%CI 37-51) *vs* 57%(95%CI 56-58) (p<0.001), in CR2 it was 36% (95%CI 27-27) *vs* 52% (95%CI 50-54) (p=0.002) and in advanced disease 35% (95%CI 29-41) *vs* 33% (95%CI 31-34) (p=0.36) in pts above and below 70 years of age, respectively. Among pts older than 70 years of age a Karnofsky score <80% was associated with improved survival and LFS in multivariate analysis (HR 0.7 95%CI 0.5-0.9 , p=0.005 and HR 0.7 95%CI 0.5-0.9 , p=0.003 respectively).
Summary/Conclusions: In AML with CR1, CR2 status at allo SCT, pts above 70 years of age have worse NRM, survival and LFS compared to pts 50-70 years of age. In pts above 70 years of age Karnofsky score is of significant importance for outcome.

P380

BLOOD BAALC AND MN1 COPY NUMBER ASSESSMENT BY DIGITAL DROPLET PCR PRIOR TO ALLOGENEIC TRANSPLANTATION PREDICTS RELAPSE IN ACUTE MYELOID LEUKEMIA PATIENTS

M. Jentzsch[1,*], M. Bill[1], J. Schulz[1], J. Grimm[1], J. Häntschel[1], S. Beinicke[1], K. Schubert[1], W. Pönisch[1], G. Behre[1], G.-N. Franke[1], T. Lange[1], V. Vucinic[1], D. Niederwieser[1], S. Schwind[1]
[1]Hämatologie und int. Onkologie, UNIVERSITÄTSKLINIKUM LEIPZIG, Leipzig, Germany

Background: Acute myeloid leukemia (AML) patients (pts) that relapse after allogeneic stem cell transplantation (HSCT) have a dismal prognosis. Identification of pts at high risk of relapse may allow preemptive therapy & improve outcomes. At diagnosis high expression of the AML associated genes *BAALC* (brain and acute leukemia, cytoplasmic) & *MN1* (meningioma 1) adversely impact on AML pts outcomes, but little is known about their usability for residual disease detection. Recently, we demonstrated a higher cumulative incidence of relapse (CIR) for pts with high pre-HSCT *BAALC* copy numbers in 82 AML pts (ASH 2016, #517). Until today no study assessed the prognostic impact of *MN1* copy numbers prior to HSCT.
Aims: To assess the prognostic impact of peripheral blood (PB) pre-HSCT *BAALC* & *MN1* copy numbers in an expanded set of AML pts in hematologic CR using digital droplet (dd) PCR.
Methods: We identified 118 AML pts (median age at HSCT 64 [range 31-76] years [y]) in first (55%) or second complete remission (CR; 23%) or CR with incomplete recovery (22%) with PB prior to HSCT (median 7, range 0-29 days) available. All pts received non-myeloablative (NMA) conditioning (fludarabine 3x30 mg & 200 cGy total body irradiation). At diagnosis karyotypes & *NPM1*, *CEBPA* gene mutations (mut) & presence of *FLT3*-TKD & *FLT3*-ITD were assessed. Quantification of *BAALC* & *MN1* normalized to *ABL1* copy numbers in pre-HSCT PB of the AML pts & in PB of healthy controls (n=7, median age 63 [range 40-82]y) was performed by ddPCR. Median follow up after HSCT for pts alive was 1.8y.
Results: European LeukemiaNet (ELN) 2010 classification was 20% favorable, 25% intermediate-I, 24% intermediate-II, 31% adverse. AML pts & healthy controls did not differ in age (*P*=1), sex (*P*=1) or mean *BAALC* (*P*=.37, Figure 1A) or *MN1* (*P*=.96, Figure 1B) copy numbers. *BAALC* & *MN1* copy numbers correlated well in pts (R=.80) & healthy controls (R=.75). The previously determined cut-off of 0.14 *BAALC* copy numbers (in 82 pts; ASH 2016, #517) defined pts with high (27%) & low (73%) pre-HSCT *BAALC* copy numbers. A cut-off of 0.74 *MN1* copy numbers was determined using the R package 'OptimalCutpoints' & defined pts with high (12%) & low (88%) pre-HSCT *MN1* copy numbers. Applying these cut-offs, 71% of the pts had low *BAALC* & *MN1* copy numbers & 10% had high *BAALC* & *MN1* copy numbers, 2% had high *MN1* but low *BAALC* & 17% had high *BAALC* but low *MN1* copy numbers. Pts with high & low pre-HSCT *MN1* copy numbers did not differ significantly in pre-treatment characteristics or remission status at HSCT (CR *vs* CRi) while pts with high pre-HSCT *BAALC* copy numbers were less often in CRi at HSCT (*P*=.02). Both high pre-HSCT *BAALC* & *MN1* copy numbers significantly associated with higher CIR (*P*=.02, Figure 1C & *P*<.001, Figure 1D, respectively). In multivariate analyses, high pre-HSCT *BAALC* (Hazard Ratio [HR] 2.5, Confidence Interval [CI] 1.1-5.7, *P*<.001) & high pre-HSCT *MN1* copy numbers (HR 5.6, CI 2.6-12.2, *P*<.001) retained their prognostic impact on CIR after adjustment for ELN 2010 genetic risk groups.

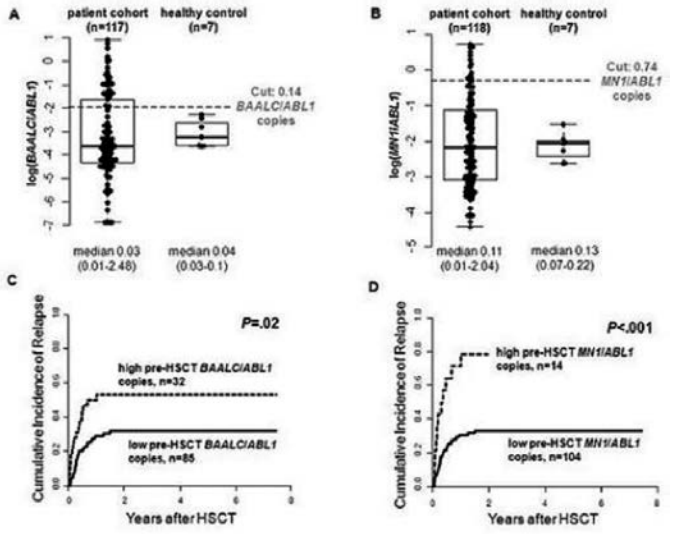

Figure 1.

Summary/Conclusions: High pre-HSCT copy numbers of *BAALC* & *MN1* associated with higher CIR in univariate & multivariate models and might indicate residual disease burden in these AML pts. High copy number pts should be closely monitored for relapse in the post-transplant period. Prospective clinical trials are needed to validate the determined cut-offs, to evaluate if *BAALC* or *MN1* copy numbers or a combination of the genes represents the most suitable prognosticator pre-HSCT and whether AML pts with high pre-HSCT *BAALC* or *MN1* copy numbers benefit from additional pre- or post-HSCT treatment.

P381

THE USE OF BPX-501 DONOR T CELL INFUSION (WITH INDUCIBLE CASPASE 9 SUICIDE GENE) TOGETHER WITH HLA-HAPLOIDENTICAL STEM CELL TRANSPLANT TO TREAT CHILDREN WITH HEMOGLOBINOPATHIES AND ERYTHROID DISORDERS

A. Bertaina[1,*], P. Merli[1], K. Mahadeo[2], A. Woolfrey[3], F. Galaverna[1], M. Algeri[1], P. Merli[1], D. Pagliara[1], G. Li Pira[1], A. Moseley[4], J. Weinberg[4], F. Locatelli[1]
[1]Ospedale Pediatrico Bambino Gesu, Rome, Italy, [2]Childrens Hospital at Montefiore, Bronx, [3]Fred Hutchinson cancer Research Center, Seattle, [4]Bellicum Pharmaceuticals Inc., Houston, United States

Background: Allogeneic HSCT from either an HLA-identical sibling or an unrelated donor is a potentially curative treatment for patients with hemoglobinopathies and erythroid disorders (ED), such as Thalassemia Major (TM),

Sickle Cell Disease (SCD) and Diamond-Blackfan Anemia (DBA). Bertaina et al (Blood, 2014) have previously shown that abTCR depleted haplo-transplantation in children with multiple types of non-malignant disorders was feasible. An ongoing Phase I/II trial evaluates the safety and efficacy of post-transplant infusion of donor T-cells transduced with the iC9 suicide gene (BPX-501 cells). (ClinicalTrials.gov identifier: NCT02065869). The iC9 vector contains the sequence for the CD19 marker, so that the BPX-501 cells (CD3+/CD19+) can be tracked in peripheral blood. We report on 15 children with hemoglobinopathies and ED.

Aims: This study was performed to determine the clinical impact of infusing BPX-501 T cells post αβ T-cell depleted haplo-identical HSCT in pediatric patients with hemoglobinopathies.

Methods: Fourteen patients were transplanted from a parent and one patient was transplanted from a sibling. Conditioning regimen included busulfan, thiotepa and fludarabine. Low dose ATG was administered to prevent graft-*versus*-host disease (GvHD) and graft failure. No post-transplantation GvHD prophylaxis was given. Median follow-up is 387 days (range 126-631 days). Six patients were males and nine females, and median age at diagnosis and at HSCT was 0.8 and 8.9 years (range 2.5-19.2), respectively. Two patients had DBA and four with SCD. All 9 TM patients were βo/βo, and among the those with TM, 4 patients belonged to class I and 3 to class II of the Pesaro classification. All 15 patients were transfusion-dependent and receiving iron-chelation therapy before haplo-HSCT. 13/15 patients maintained full donor chimerism. The patients with secondary graft failure were re-transplanted from the same donor and maintained full donor chimerism.

Results: All patients are alive and well with no Treatment Related Mortality (TRM). Initial discharge was at a median of 23.5 days(range 14-55) and there were two patients re-hospitalized at 30, 163 days respectively. Grade I/II skin acute GvHD occurred in four patients and one patient had acute skin GvHD Grade IV. No chronic GVHD was observed. Median time to neutrophil recovery was 14 days (range 10-32 days), while median time to platelet recovery was 11 days (range 8-12 days). Median time to last RBC transfusion was 8 days (5 – 34 days). See Figure 1 for individual Hemoglobin levels. Median time of infusion of $1x10^6$ BPX-501 T cells/kg was 14 days after HSCT (range 10-26). BPX-501 cells expanded after infusion and still persist in all patients. Immune reconstitution with normal cellular and humoral immunity present at 180 days post HSCT. All patients remain transfusion-free with a median hemoglobin of 11 or greater after 6 months.

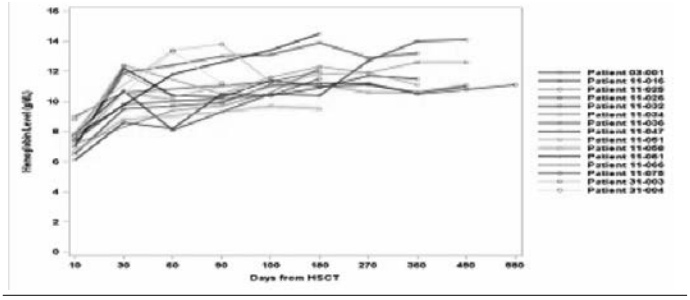

Figure 1.

Summary/Conclusions: These data suggest that Haplo-HSCT combined with infusion of BPX-501 T cells with a suicide gene may be a safe and curative option for children with hemoglobinopathies and ED who lack a matched donor. Infusion of gene modified T cells with an inducible suicide mechanism, combined with selective αβ T-cell depletion, offers the potential to rapidly reverse GvHD and eliminate the need for the use of GvHD prophylaxis. Additionally, this approach results in rapid hematological and immune reconstitution for Haplo-HSCT recipients.

P382

EXCELLENT RESPONSE, LOW TRM AND GOOD SURVIVAL IN PATIENTS WITH THERAPY-REFRACTORY AGVHD AFTER TREATMENT WITH EQUIPOTENT MSCS OF A SERUM-FREE MSC-BANK GENERATED FROM POOLED BM-MNCS OF MULTIPLE DONORS

Background: All clinical data published thus far on the use of MSCs were generated using cells expanded from individual bone marrow donors hence suffer from huge inter-donor differences in MSC generation, expansion and immunomodulatory potential. To control these variables and to be able to administer to all patients highly similar MSC products, we established a proprietary pooling procedure and generated a large bank of MSC end-of-passage-1 vials from which end-of-passage-2 MSC products are expanded for clinical use. The manufacturing process is fully GMP-compliant and generates an animal serum-free MSC product with near-identical phenotype and in-vitro immunomodulatory potency. Importantly, they showed a significantly higher allosuppressive potential than the mean allosuppressive potential of MSCs generated from individual donors. All tested individual MSC doses were equipotent in suppression of the alloantigen-driven reaction in mixed lymphocyte reactions (Kuçi *et al.* Haematologica 2016: 101 (8); 985-994).

Aims: A "hospital exemption" issued by the national regulatory authority Pau-Ehrlich-Institute (Number: PEI: A.11748.01.1) licenses the clinical use of these products for patients with steroid refractory GVHD. On the basis of this licence patients were with severe GVHD were treated who were either non responsive to any other treatment or who were resistant steroids after 7 days.

Methods: Using these standardized MSC products altogether 52 patients were treated between December 2014 and December 2016. Patients were male (n=31, 60%) or female (n=21, 40%) and were transplanted for leukemia (n=38, 73%) or non-malignant (n=14, 27%) diseases. Median age was 8y (range: 0.5-52 years). Stem cell source MSD (n=9, 17%), MUD (n=33, 63%) or MMFD (n=10, 19%) and derived from BM (n=27, 52%), peripheral blood (n=24, 46%) or cord blood (n=1, 2%). Patients were suffering from aGVHD grade II (n=3, 5.5%), III (n=14, 27%), or IV (n=31, 60%) or extensive cGVHD (n=4, 7.5%). Acute GVHD occurred at a median time of 52 days (5-280 days) after transplant. Patients received in weekly intervals up to four MSC infusions after having failed to respond to the treatment with either two lines (n=10, 19%), three lines (n=20, 38%), four lines (n=10, 19%), 5 lines (n=7, 13%), six lines (n=4, 8%), or 7 lines (n=1, 2%) of immune suppressive drugs.

Results: Response was defined as either complete response (CR) in patients who showed complete resolution of all signs of GVHD, partial response (PR) in patients who showed one overall GVHD grade less according to the Glucksberg criteria, or non response (NR) at day 28 after first MSC transfusion.

At day +28, 12 patients (23%) achieved CR, 29 patients (57%) PR (overall response= 80%), 9 patients (17%) NR, and in 2 patients (4%) no data were available at day +28. At the last follow up of GVHD**,** 29 patients (56%) were in CR, 13 patents (25%) in PR, 9 patients (17%) in NR, and for 1 patient (2%) no data were available. At 2 years these response rates resulted in a non-relapse mortality rate (NRM) of 27±6%, cumulative relapse incidence (CIR) of 14±4%, and an overall survival rate (OS) of 59±9%. Patients with aGVHD III and IV had an OS survival probability at 2 years of 77±12% and 59±35%, respectively thus dramatically in excess of expected survival rates for patients with such severe aGvHD. There was no difference between younger (n=40) and older patients (n=12) than 16 years.

Summary/Conclusions: Treatment with standardized equipotent MSCs from the "FRANKFURT MSC-BANK" offers an excellent chance to overcome treatment-resistant and steroid-refractory acute GVHD.

P383

HIGHER PEAK TACROLIMUS CONCENTRATIONS AFTER ALLOGENEIC TRANSPLANTATION INCREASE THE RISK OF ENDOTHELIAL CELL DAMAGE COMPLICATIONS

T. Morishita[1,*], M. Ohbiki[1], M. Osaki[1], M. Yoshino[1], S. Ikeno[1], M. Nakashima[1], T. Sato[1], Y. Kagaya[1], Y. Ozawa[1], K. Miyamura[1]

[1]Hematology, Japanese Red Cross Nagoya Daiichi Hospital, Nagoya, Japan

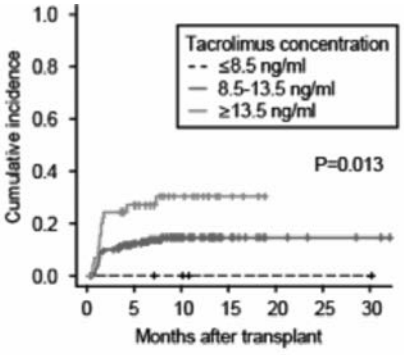
Background: Noninfectious transplantation-related complications (TRC) such as GVHD and endothelial cell damage (TRC-EC) including sinusoidal obstructive syndrome (SOS), transplant-associated microangiopathy (TAM), idiopathic pneumonia syndrome (IIP) are dismal complications after allogeneic hematopoietic stem cell transplantation (allo-HSCT).Calcineurin inhibitors such as tacrolimus (TAC) have been broadly utilized to manage post-transplant complications. Higher blood levels of TAC were expected to reduce the risk of GVHD, but may increase the risk of endothelial damage. Since TRC-EC often developed in patients with GVHD, it is difficult to judge appropriateness of immunosuppression clinically.

Aims: Here we evaluated the impact of TAC blood levels upon TRC-EC occurrence and prognosis after allo-HSCT.

Methods: Two hundred sixty-one consecutive patients (pts) who received TAC as a GVHD prophylaxis after allo-HSCT at our institute from 2009 to 2015 were candidates for this retrospective study. Pts who received haploidentical allo-HSCT

and pts with unavailable TAC concentration data were excluded. A total of 253 pts was eligible. All pts received standard GVHD prophylaxis by continuous intravenous (iv) TAC with starting dose of 0.02 mg/kg/day from 1 day before allo-HSCT (day -1) and iv methotrexate on day 1, 3, 6 at dose of 10 mg/m2, 7mg/m2, 7 mg/m2, respectively. TAC dosage was adjusted to target the serum concentration of 8-12 ng/ml until at least day 30 and then tapered. TAC was rapidly tapered in case of the pathological diagnosis of TAM.TAC serum concentration was sequentially examined triad weekly until day 35 at least. The primary endpoint of this study was to evaluate the cumulative incidence of TRC-EC in relation to weekly mean/peak TAC concentration. Secondary endpoint was OS.

Results: Median patient age was 45 years (16-68). The risks of disease were standard in 168 and high in 85 pts. Forty pts were diagnosed of TRC-EC; SOS: 7 pts (median onset: day 24 (17-40)), TAM: 27 pts (median onset: day 40 (25-128)), IIP: 6 pts (median onset: day 161.5 (46-223)).The cumulative incidence of TRC-EC at day 250 was 0.16 (95%CI, 0.12-0.21). Univariate analysis showed that higher peak TAC concentrations (PTC) during day 22-28 (P=0.013), male pts (P=0.018) and grade 3-4 acute GVHD (P<0.01) were significantly associated with the development of TRC-EC. Higher mean TAC concentrations (MTC) during day 0-7 was correlated with higher incidence of TRC-EC, but not significant (P=0.069). In multivariate Fine-Gray analysis, high PTC during day 22-28 (HR: 1.92, 95%CI, 1.07-3.45, P=0.028) and grade 3-4 acute GVHD (HR: 8.33, 95%CI, 4.18-16.59, P<0.01) remained associated with TRC-EC occurrence. The probability of OS at 15-months was 0.56 (95%CI, 0.47-0.64). Univariate analysis showed that pts diagnosed TRC-EC (P<0.01), pts older than 50 (P<0.01), pts with high disease risk (P<0.01) and pts who received reduced intensity conditioning regimens (P=0.010) were significantly associated with poor OS. PTC and MTC at any time-period were not significant factors for OS. By Cox proportional-hazards regression models, TRC-EC diagnosis (HR: 1.90, 95%CI, 1.16-3.11, P=0.011) and high disease risk at transplant (HR: 1.76, 95%CI, 1.14-2.73, P=0.011) were significantly associated with poor OS (Figure 1).



The cumulative incidence curves of TRC-EC.
The peak tacrolimus concentrations (PTC) during 22-28 days after allo-HSCT were divided into low (≤8.5ng/ml), intermediate (8.5-13.5 ng/ml) and high (≥13.5 ng/ml). The incidence of TRC-EC was proportionally increased with the PTC.

Figure 1.

Summary/Conclusions: Higher peak TAC concentrations during 22-28 days after allo-HSCT increased the risk of TRC-EC. And the development of TRC-EC was associated with poor OS.

Background: T-cell replete haplo-identical stem cell transplantation (haploSCT) is a valid therapeutic option for adult patients (pts) with high risk acute myeloid leukemia (AML) lacking a sibling or unrelated donor. However the impact of reduced intensity (RIC) *vs* myeloablative (MAC) conditioning regimens is not conclusive as no randomized study addressing this question is yet available.

Aims: In the present study we compared the outcome of RIC and MAC in pts with AML older than 45 years (yrs) undergoing haploSCT. The aim of the study was to confirm the efficacy and feasibility of RIC among a population for which the choice of conditioning intensity is more related to center strategy than pts comorbidities or disease status.

Methods: We retrospectively compared the outcomes of 614 pts with de novo or secondary AML transplanted between 2007 and 2015 from an haplo-identical donor using either RIC (n=365) or MAC (n=249) regimens. Age was categorized in three subgroups (45-55 yrs, 55-60 yrs, >60 yrs). Patients receiving a previous allogeneic transplantation were excluded. RIC was defined according to EBMT definitions.

Results: The median follow up for MAC and RIC was 24 and 20 months, respectively and the median year of transplant was 2013 for both. Pts receiving a RIC were older (55 yrs in MAC *vs* 61 yrs in RIC, p=<10^{-4}). Secondary AML was more frequent in RIC *vs* MAC (31% *vs* 22%) while 77% of MAC and 68% of RIC were transplant for de novo AML, p=0.01. No differences were found on disease status and Karnofsky performance status (KPS) at transplant: pts were in CR1 (MAC: 44%, RIC: 40.5%), CR2/3 (MAC: 17%; RIC: 17%) or had active disease (MAC: 40%; RIC: 43%), p=0.68; 12% of pts in both groups had KPS<80, p=0.95. The most frequently used MAC regimen was TBF (56%), while in RIC it was miniTBF (27%) and low dose TBI+Fludarabine (24%). RIC regimens were more frequently associated with the use of peripheral blood as stem cell source (MAC 42% *vs* RIC 55%, p=0.002). Post-transplant cyclophosphamide was used in 69% of both RIC and MAC, p=0.39. Main outcomes were not different according to conditioning regimen: at 2 years RI was 26% *vs* 32% (p=0.29), NRM 31% *vs* 34% (p=0.62), aGVHD II-IV 24% *vs* 31% (p=0.05), and cGVHD 27% *vs* 26% (p=0.94), LFS 42% *vs* 39% (p=0.17), OS 46% *vs* 39% (p=0.15), GRFS 36% *vs* 28% (p=0.10) for MAC *vs* RIC, respectively. The results according to RIC and MAC were not different in any of the three age subgroups. 338 patients died; main causes of death were infections and GVHD to be followed by disease recurrence. In multivariate analysis, the type of conditioning regimen was not associated with risk of relapse or treatment failure: RI (HR: 1.22, p=0.28), NRM (HR: 0.92, p=0.63), acute GVHD grade II-IV (HR: 1.14, p=0.48), chronic GVHD (HR: 1.26, p=0.30), LFS (HR: 1.03, p=0.77), GRFS (HR: 1.07, p=0.55), OS (HR: 1.05, p=0.68). Disease status was associated with outcomes (active disease *vs* CR): RI (HR: 2.44, p=<10^{-4}), LFS (HR: 1.75, p=<10^{-4}), GRFS (HR: 1.72, p=<10^{-4}), OS (HR: 1.71, p=<10^{-4}) as well as KPS>90: NRM (HR: 0.53, p=0.0002), LFS (HR: 0.67, p=0.001), GRFS (HR: 0.74, p=0.014), OS (HR: 0.62, p=0.0002).

Summary/Conclusions: In our study no differences were found between RIC and MAC regimens for haplo-SCT in adults with AML including the age stratified populations. Disease status and performance status were the major predictors of transplantation outcome, while conditioning intensity had no effect. These results may serve as the background for a well design randomized study comparing RIC *vs* MAC for haplo-SCT in adult pts with AML.

Background: Patients with aggressive adult T cell leukemia-lymphoma (ATL) have a dismal outcome even with an intensive chemotherapy. There is still controversy regarding the indication of up-front allogeneic hematopoietic stem cell transplantation (allo-HSCT) as no prospective randomized controlled trial (RCT) has been conducted due to a rarity of patients with ATL even in Japan.

Decision analysis is a computerized modeling analysis which can simulate the clinical outcomes of different therapeutic strategies and identify an appropriate therapeutic strategy.

Aims: The aim of this study is to compare the life expectancy (LE) of chemotherapy followed by up-front allo-HSCT to that of chemotherapy alone using decision analysis in patients with aggressive ATL using database constructed by a nationwide survey.

Methods: We constructed a Markov decision analysis model to compare the outcomes in 2 therapeutic strategies: chemotherapy followed by upfront allo-HSCT *vs* chemotherapy alone. The transition probabilities between each health states were calculated from the database of 1,792 patients and patients were stratified into low-, intermediate- and high-risk groups according to the risk stratification system which we developed previously (Fuji S *et al.* 18th International Conference on Human Retrovirology). The model simulated the LE, quality-adjusted LE (QALE) and survival curve after diagnosis of aggressive ATL. Since QoL data for patients with aggressive ATL are lacking, estimates from a similar decision analysis study of patients with acute myeloid leukemia were used. In terms of the timing of up-front allo-HSCT, it was set as all patients receive up-front allo-HSCT from 2 to 6 months if ATL did not progress before allo-HSCT. We used the TreeAge Pro 2016 software package for decision analysis (TreeAge Software Inc., Williamstown, MA).

Results: In all patients, up-front allo-HSCT was associated with higher LE in comparison to chemotherapy alone (2.26 years *vs* 1.75 years). Stratified into 3 groups according to the prognostic scoring system, LE of up-front allo-HSCT was higher compared to that of chemotherapy alone in the intermediate- (2.27 years *vs* 1.66 years) and high-risk groups (1.50 years *vs* 0.91 years). The estimated survival curve depicted by TreeAge showed the superiority of up-front allo-HSCT as shown in Figure 1A-D. The Monte Carlo simulation showed that the probability of superiority of up-front allo-HSCT was 100% in all patients, 97.1% in the low-risk group, 100% in the intermediate-risk group, and 100% in the high-risk group in terms of LE, and was 99.8% in all patients, 75.2% in the low-risk group, 100% in the intermediate-risk group, and 100% in the high-risk group in terms of QALE.

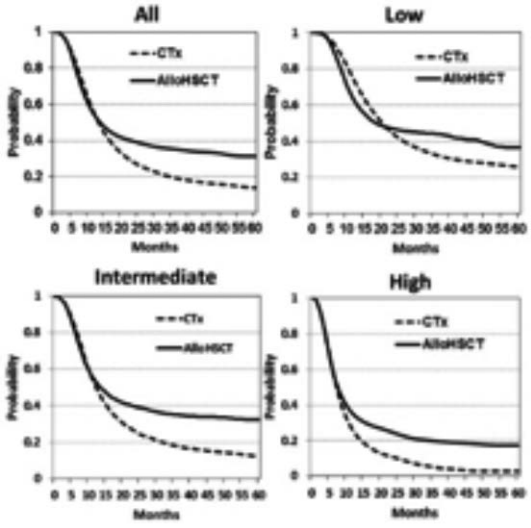

Figure 1.

Summary/Conclusions: Based on decision analysis, up-front allo-HSCT was associated with higher LE and QALE in the intermediate- and high-risk groups in comparison to chemotherapy alone in patients with aggressive ATL. In the absence of prospective randomized controlled trials, our results suggest that up-front allo-HSCT for aggressive ATL is the favored treatment strategy in the intermediate- and high-risk groups.

P386

OUTCOMES OF THIOTEPA BASED REDUCED-INTENSITY CONDITIONING VERSUS STANDARD REDUCED-INTENSITY CONDITIONING IN ADULT PATIENTS UNDERGOING DOUBLE-UNIT CORD-BLOOD HEMATOPOIETIC STEM CELL TRANSPLANT

P. Sharma[1,*], D. Pollyea[1], C. Smith[1], E. Purev[1], M. Kamdar[1], B. Haverkos[1], D. Sherbenou[1], J. Gutman[1]
[1]Division of Hematology, University of Colorado, Denver, United States

Background: Cord blood transplantation (CBT) is an established alternative source for hematopoietic stem-cells in patients without matched donor. However, the most commonly used high-dose total-body-irradiation (TBI) myeloablative conditioning (MAC) results in high treatment related mortality (TRM). Non-myeloablative and reduced-intensity conditioning (RIC) have been studied to decrease TRM and provide curative chance to the elderly and those with comorbidities. However, these strategies are associated with higher relapse-rate and graft rejection. A novel-RIC using addition of thiotepa and higher dose of TBI to standard RIC has shown to result in sustained donor engraftment. Our study compares transplant-related-outcomes in patients who underwent first double-unit CBT with standard-RIC regimen of fludarabine (Flu, 200mg/m^2), cyclophosphamide (Cy, 50mg/kg), and TBI (200cGy or 300cGy) *versus* this standard-RIC regimen with addition of thiotepa (10mg/kg) and increased dose of TBI (400cGy).

Aims: 1. To compare transplant related outcomes in CBT recipients who received *standard-RIC* (FluCyTBI) to those who received *novel-RIC* (FluCy with addition of thiotepa and increased dose of TBI). 2. To identify optimal conditioning regimen in patients undergoing UCT.

Methods: After IRB approval, consecutive patients undergoing CBT from 08/2009 to 08/2016 were evaluated and data retrospectively abstracted. Patient selection, graft-*versus*-host disease prophylaxis and transfusions were per institutional standards and conditioning regimens were compared as described.

Results: Of the 99 patients who underwent allogeneic double-CBT, 52 received standard-RIC and 47 received novel-RIC. Median age at transplant was 67 years (range, 24-74) and 54 years (range, 25-67) in standard-RIC and novel-RIC cohort respectively. Acute myeloid leukemia was the major indication for transplant in both cohorts. Median hematopoietic stem-cell transplant comorbidity-index (HSCT-CI) was 3 (range, 0-6) and 1 (range, 0-6) in standard-RIC and novel-RIC groups respectively. Four patients suffered engraftment failure (2 in each cohort). Median neutrophil engraftment was 13 days (range, 6-42) and 21 days (range, 12-43) while median platelet engraftment was 37 days (range, 26- 70) and 38 days (range, 24-74) in standard-RIC and novel-RIC groups respectively. Fifty-three suffered acute-GVHD which occurred in 21 (40%) patients (grade 2-4: n=15, 29%; grade 3-4: n=2, 4%) in standard-RIC group and in 32 (68%) patients (grade 2-4: n=29, 62%; grade 3-4: n=5, 11%) in novel-RIC group. Chronic-GVHD (cGVHD) occurred in 18 patients (n=7, 14% in standard-RIC; n=11, 23% in novel-RIC group). The one-year cumulative incidence of relapse was 36% (n=15) in standard-RIC while it was 15% (n=5) in novel-RIC cohort. Median relapse free survival (RFS) was significantly improved in novel-RIC cohort compared to standard-RIC (HR, 0.32, CI:0.11- 0.76, p=0.01). Median RFS was 29 months in standard-RIC cohort while median RFS was not reached in novel-RIC cohort. The one-year cumulative incidence of transplant related mortality (TRM) was 22% (n=10) in those who received standard-RIC while it was 16% (n=7) in those who received novel-RIC. TRM was not significantly different between the standard-RIC and novel-RIC cohorts. Median follow-up in standard-RCI cohort was 9.3 months (range, 0.16- 79) and 13 months (range, 1.4- 36) in novel-RCI cohort. The overall survival (OS) was significantly better in novel-RCI cohort compared to standard-RCI (HR 0.49, CI: 0.25- 0.94, p= 0.03). Median OS was 17 months in standard-RIC cohort while median OS was not reached in novel-RIC group (Figure 1).

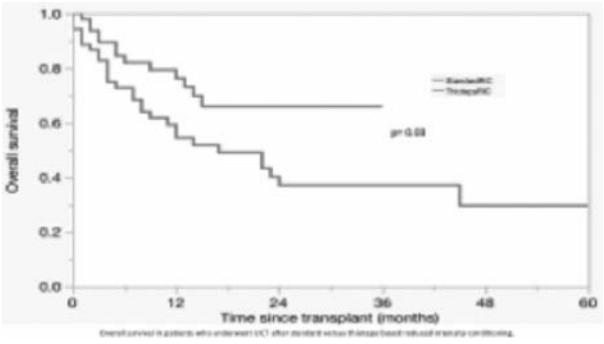

Figure 1.

Summary/Conclusions: In our study, RIC consisting of FluCy with addition of thiotepa and increased dose of TBI in patients undergoing double-cord UCT was associated with improved OS and improved RFS without increase in TRM as compared to standard RIC. While older and more comorbid patients might experience increased TRM with the thiotepa based regimen, these data suggest that consideration of this regimen may be appropriate in fit, older patients.

P387

INTERFERON-A IS EFFECTIVE FOR TREATMENT OF MINIMAL RESIDUAL DISEASE IN PATIENTS WITH ACUTE LEUKEMIA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

X.-D. Mo[1,*], X.-H. Zhang[1], L.-P. Xu[1], Y. Wang[1], C.-H. Yan[1], H. Chen[1], Y.-H. Chen[1], W. Han[1], F.-R. Wang[1], J.-Z. Wang[1], K.-Y. Liu[1], X.-J. Huang[1]
[1]Peking University People's Hospital, Institute of Hematology, Beijing, China

Background: Post-transplant relapse is a major cause of transplant failure. Because impending relapse can be indicated by minimal residual disease (MRD) after allogeneic hematopoietic stem cell transplantation (allo-HSCT), MRD-directed intervention may be a reasonable option for relapse prophylaxis.

Aims: We investigated the efficacy of MRD-directed interferon-α (IFN-α) treatment in acute leukemia patients who were positive for MRD after allo-HSCT.

Methods: A total of 107 patients who were MRD-positive after allo-HSCT were enrolled. MRD-positive status was defined as positivity for leukemia-associated aberrant immune phenotypes or positivity for Wilms' tumor gene 1 in a single bone marrow sample. Recombinant human IFN-α-2b injections were administered subcutaneously 2–3 times per week for 6 months.
Results: The 2-year cumulative incidence of severe acute and chronic graft-*versus*-host disease after IFN-α treatment was 5.7% and 6.6%, respectively. Eighty-one (75.7%) patients turned MRD-negative after IFN-α treatment, including 42 (39.3%), 6 (5.6%), 7 (6.5%), and 26 (24.3%) who turned MRD-negative 1, 2, 3, and >3 months after MRD-directed IFN-α treatment, respectively. Twelve patients showed relapse after IFN-α treatment, and 4 patients died of non-relapse mortality (NRM). The 2-year cumulative incidence of relapse and NRM after IFN-α treatment was 11.5% and 4.3%, respectively. The 2-year probabilities of event-free survival and disease-free survival after IFN-α treatment were 66.5% and 82.4%, respectively. Persistent MRD after IFN-α treatment was significantly associated with higher relapse risk and poorer survival.
Summary/Conclusions: These data confirmed that MRD-directed IFN-α treatment is effective for patients who were MRD-positive after allo-HSCT.

P388

COMPARABLE LONG-TERM OUTCOME AFTER ALLOGENEIC STEM-CELL TRANSPLANTATION FOR OLDER PATIENTS (AGE ≥50 YEARS) WITH AML FROM SIBLING AND MATCHED UNRELATED DONORS. A REPORT ON BEHALF OF THE ALWP OF EBMT

A. Shimoni[1,*], M. Labopin[2], B. Savani[3], L. Volin[4], J. Finke[5], D. Niederwieser[6], G. Ehninger[7], D. B. Blaise[8], D. Beelen[9], R. T. Tabrizi[10], H. Sengeloev[11], A. Ganser[12], J. C. Cornelissen[13], M. Mohty[2], A. N. Nagler[1]
[1]CHAIM SHEBA MEDICAL CENTER, Tel-Hashomer, Israel, [2]Hôpital Saint Antoine, Paris, France, [3]Vanderbilt University , Nashville, United States, [4]HUCH Comprehensive Cancer Center, Helsinki, Finland, [5]University of Freiburg, Freiburg, [6]University Hospital Leipzig, Leipzig, [7]Universitaetsklinikum Dresden, Dresden, Germany, [8]Institut Paoli Calmettes Marseille, Marseille, France, [9]University Hospital, Essen, Essen, Germany, [10]CHU Bordeaux, Bordeaux, France, [11]National University Hospital , Copenhagen, Denmark, [12]Hannover Medical School, Hannover, Germany, [13]Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: Allogeneic stem-cell transplantation (SCT) is curative therapy in AML. Most deaths after SCT occur within the first 2 years. Prior large cohort studies showed that patients (pts) surviving leukemia free 2 years after SCT have high probability of survival at 10 years. Most of these studies were done in younger pts following myeloablative conditioning (MAC). Marked improvement has been achieved in SCT from unrelated donors (UD) in recent years due to improvement in tissue typing, donor selection and supportive care. However, there is relatively limited data on the comparative long-term outcomes (beyond 10 years) of SCT in AML pts (age ≥50 years) from sibling and UD in this setting.
Aims: To compare the long-term outcomes after SCT from sibling and UD using different conditioning intensities in AML pts age ≥50 years.
Methods:
We analyzed long-term outcomes in a relatively large cohort of pts with de-novo AML (n=1134), age ≥50 years, who were alive and leukemia-free 2 years after SCT from matched siblings (n=848) or UD (n=286), in the years 2000-2007, median follow up 8.6 years (2-16.4).
Results: The median patient age was 56 years (50-75) and 58 years (50-74) after SCT from siblings and UD, respectively (P=0.005). 77%, 12% and 11% in the sibling group were in CR1, CR2 and active leukemia at SCT compared to 50%, 25% and 25% in the UD group, respectively (P<0.001). 37% and 38% had reduced-intensity conditioning according to EBMT definitions (P=0.78), while 27% and 70% had in-vivo T-cell depletion (TCD), respectively (P<0.001). Chronic GVHD prior to the 2 year time-point occurred in 61% and 53%, respectively (P=0.02). The 10-year leukemia-free survival (LFS) of pts surviving leukemia-free 2 year after SCT was 72% (68-75) and 62% (55-70) after SCT from sibling and UD, respectively (P=0.30). Multivariate analysis (MVA) identified active leukemia at SCT (HR 1.8, P<0.001) or CR2 (HR 1.5, P=0.02) compared to CR1 and female recipient (HR 0.7, P=0.005) as independent factors predicting LFS. The donor type, conditioning regimen, age, cytogenetics and prior acute or chronic GVHD were not significant. The 10-yearr overall survival was 74% (70-77) and 66% (59-74), respectively (P=0.42). Relapse occurred in 15% (13-18%) and 17% (12-22%, P=0.97), respectively. MVA identified SCT in active disease (HR 2.2, P<0.001) or CR2 (HR 1.9, P=0.006), poor cytogenetics (HR 5.8, P=0.02), in-vivo TCD (HR 5.5, P=0.03) and female gender (HR 0.6, P=0.03) as risk factors for late relapse. Non-relapse mortality (NRM) occurred in 13% (11-16%) and 21% (15-28%, P=0.15), respectively. Advanced age was the only risk factor for late NRM (HR, 1.6, P=0.03). Donor and conditioning type were not predictive of late relapse or NRM. A center effect was documented for NRM (P<0.001) and LFS (P=0.05). There were 209 late deaths after sibling and 72 after UD SCT. Relapse was the cause of death in 53% and 37% of late deaths, respectively (P=0.06). GVHD was the cause of death in 16% and 22% and infection in 9% and 19%, respectively (P=0.05). Second malignancy was the cause of death in 13% and 12% of late deaths, respectively.
Summary/Conclusions: Long term outcome is similar after SCT form sibling or UD in pts with AML, age ≥50 years. Pts who are leukemia free 2 years after SCT can expect good and similar subsequent outcome with both donor types. Disease status was the major predictor of subsequent LFS while conditioning intensity had no effect. While relapse is the major cause of late death after both donor types, NRM and in particular GVHD and infections are more common causes of late death after SCT from UD.

Background: Myelodysplastic syndrome (MDS) is a heterogeneous myeloid stem cell disorder with ineffective hematopoiesis, dysplastic cell morphology, and a propensity for progression to acute myeloid leukemia. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the only curative therapy for MDS. In recent years, azacitidine (AZA) has been increasingly used as pre-transplant induction therapy in high-risk MDS patients. However, the benefits of pretransplant therapy in these patients are unclear, and the optimal therapy regimen remains unknown.
Aims: We conducted a retrospective analysis to elucidate the clinical impact of prior treatment with AZA on outcomes after allo-HSCT in high-risk MDS patients.
Methods: Clinical data were collected from the registry database of the Japan Society for Hematopoietic Cell Transplantation. We selected patients with high-risk MDS at diagnosis (IPSS intermediate 2 or high), aged 16 years or older, who underwent their first transplantation between January 2009 and December 2014 and received AZA or best supportive care (BSC) before allo-HSCT. Patients who received conventional chemotherapy or immunosuppressive therapy prior to allo-HSCT were excluded. We compared overall survival (OS), relapse, non-relapse mortality (NRM), and hematopoietic recovery after allo-HSCT patients were pretreated with AZA or BSC.
OS was estimated by the Kaplan–Meier method, and a log-rank test was used for comparisons. Relapse and NRM were considered competing risk events and were compared using Gray's test. The cumulative neutrophil and platelet recoveries were also compared by Gray's test, considering death without these events as a competing risk. In a multivariate analysis, the Cox proportional hazard model and Fine-Gray methods were used for OS and cumulative incidence of relapse and NRM and hematopoietic recovery, respectively, using the following variables: age, gender, performance status at transplantation, marrow blast at diagnosis, cytogenetic risk, donor source, donor-recipient gender mismatch, ABO mismatch, and conditioning regimen.
Results: Of the 485 patients, 161 patients (33.2%) received AZA and 324 patients (66.8%) received BSC before allo-HSCT. The median age was 60 (18–70) and 56 (18–74) years, respectively (P=0.002). A higher proportion of BSC patients received cord blood transplantation (P=0.005). Bone marrow blast at diagnosis was significantly higher in AZA patients (P <0.001) and cytogenetic risk was better in AZA patients (P=0.02) than those in BSC patients. No differences were observed in other factors. The 2-year OS rate (46.7% and 50.8%, P=0.66), relapse (31.5% and 28.6%, P=0.59), NRM (26.5% and 26.1%, P=0.99), 30-day neutrophil engraftment (88.2% and 83.6%, P=0.18), and 60-day platelet engraftment (72.0% and 69.4%, P=0.36) were not significantly different between the AZA and BSC groups. In multivariate analysis, AZA and BSC showed comparable OS (HR, 1.16; P=0.31), relapse (HR, 1.13; P=0.50), NRM (HR, 0.92; P=0.64), neutrophil engraftment (HR, 1.01; P=0.89), and platelet engraftment (HR, 1.07; P=0.59).
Summary/Conclusions: Our study showed that pretransplant AZA and BSC provide similar outcomes of allo-HSCT in high-risk MDS patients. Further analysis is needed to clarify the role of pretransplant therapy in high-risk MDS and to identify the subset of patients who may benefit from pretransplant AZA.

LOW-DOSE DECITABINE IMPROVES PLATELET RECOVERY IN PATIENTS WITH ISOLATED THROMBOCYTOPENIA AFTER HSCT

Y. Han[1,2,*], Y. Tang[1], Y. Zhao[1], M. Huang[1], J. Chen[1], J. Qi[3], Y. Wang[1], X. Wu[1], X. Ma[1], F. Chen[1], X. He[1], C. Ruan[1], D. Wu[12]
[1]The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, [2]Institute of Blood and Marrow Transplantation,Collaborative Innovation Center of Hematology, [3]Soochow University, Suzhou, China

Background: Isolated thrombocytopenia is a common complication of hematopoietic stem-cell transplantation (HSCT), which was defined as consistent low platelet counts with recovery of the other two cell lines after transplantation. This status leads to an increased risk of life-threatening hemorrhage, frequent requirements of platelet transfusion and extended hospital stays, representing a challenging clinical problem. Previous studies have demonstrated that decitabine, a hypomethylating agent, may increase platelet counts by promoting megakaryocyte maturation and platelet release in mouse model.
Aims: In order to investigate the role of decitabine in patients after HSCT suffering from isolated thrombocytopenia, we conduct a clinical trial to validate this effect in post-HSCT setting.
Methods: We performed a prospective open-label study to evaluate the treatment of low-dose decitabine in patients with hematological malignancies who received allogeneic HSCT and suffered from isolated thrombocytopenia. The inclusion criteria were: (1) Platelet count ≤30 × 109/L persistently at day 60 post-HSCT or later; (2) Recovered neutrophil and hemoglobin; (3) Full donor chimerism; and (4) No response to conventional treatments for a duration of at least 4 weeks. Patients with malignancy relapse, active infections, uncontrolled graft-*versus*-host disease, severe organ damage or transplant-related thrombosis were excluded. From July 2013 to July 2016, 38 patients were randomly assigned into either the control group to receive conventional treatment only, or the test group to receive additional decitabine (15mg/m^2, intravenously daily for 3 consecutive days).
Results: Major response was observed in 16 out of 19 patients (84.2%) in decitabine group, with a median time of 22 days to achieve platelet transfusion-independence. Two patients (10.5%) showed a minor response and 1 patient (5.3%) failed. In contrast, 3 out of 19 patients in the control group (15.8%) showed a major response, 2 patients (10.5%) showed a minor response, 14 patients (73.7%) did not show any improvement, of which 1 patient died of severe hemorrhage in week 5. For bone marrw morpholocial analysis, all 38 patients showed low levels of megakaryocytes at week 0. However, the megakaryocyte counts in decitabine group were significantly increased at week 4, while no significant difference was recorded in control group. After decitabine treatment, we did not observe a change in anti-platelet antibodies levels and T cell subsets ratios. However, reactive oxygen species (ROS) and megakaryocyte counts increased in the test group. No considerable myelosuppression, febrile neutropenia, and nonhematologic toxicities associated with the treatment were observed.
Summary/Conclusions: Our data showed an encouraging efficacy of decitabine in patients after HSCT suffering from isolated thrombocytopenia owing to remarkably increased megakaryocyte counts. Decitabine may improve isolated thrombocytopenia via regulating ROS and megakaryocyte reconstitution.

Thalassemia

QUANTITATIVE PROTEOMICS OF PLASMA EXTRACELLULAR VESICLES TO IDENTIFY NOVEL BIOMARKERS OF CLINICAL SEVERITY FOR HBE/B-THALASSEMIC PATIENTS

J. Kittivorapart[1,2,3,*], V. Karamatic Crew[1], N. Siritanaratkul[4], A. Mark Toye[1,2]
[1]Bristol Institute for Transfusion Sciences (BITS), NHS Blood and Transplant, [2]School of Biochemistry, University of Bristol, Bristol, United Kingdom, [3]Department of Transfusion Medicine, [4]Department of Medicine, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand

Background: Hemoglobin (Hb) E/β-thalassemia has a wide spectrum of clinical manifestations that cannot be explained purely by its genetic background. Extracellular vesicles (EV) are one factor that may indicate and/or contribute to disease severity because there is an observed increase in EV release due to the enhanced oxidative stress in thalassemic erythrocytes.
Aims: This study aims to explore the differences in protein composition and abundance between circulating EV from HbE/β-thalassemic patients and normal individuals.
Methods: 15 HbE/β-thalassemia patients and 15 matched-controls from Thailand were fully consented and recruited for this study. Pooled EVs isolated from five thalassemic samples were compared to pooled EVs from five matched controls using a Duplex-Tandem Mass Tag (TMT) mass spectrometry (TMT-MS) analysis. This experiment was repeated three times in total, using different patient and control samples to identify consistent alterations of protein expression in EVs. Finally, protein differences were also confirmed using Western blotting.
Results: The total proteins identified across the three experimental TMT-MS datasets ranged from 1,764 to 2,534 proteins. When restricted to proteins that contained more than one unique peptide, the range of proteins was reduced to 685 to 1,127 proteins. Many proteins were previously reported EV constituents. 19 proteins were consistently increased in patient samples compared to controls across all data sets. The majority of these proteins were chaperone proteins and antioxidant enzymes. Alpha Hemoglobin Stabilizing Protein (AHSP) had the highest increase of between 31 to 47-fold. Other proteins that exhibited increased abundance in thalassemic circulating EV included catalase, superoxide dismutase, T-complex proteins, heat shock protein 70 and ferritin light chain. Importantly, the heme scavenger and plasma proteins – haptoglobin and hemopexin were observed to be consistently decreased in patients' EV across all data sets. Immunoblotting results corroborated the TMT-MS findings.
Summary/Conclusions: We have successfully identified consistent alterations in protein expression levels between EV generated by HbE/β-thalassemic patients and normal individuals. These findings may potentially lead to the development of a prognostic marker, and therefore may improve the therapeutic outcome for the patients suffering from thalassemia.

P392

A SELECTIVE ORAL GLYT1 INHIBITOR IMPROVES ANEMIA IN A MOUSE MODEL OF BETA-THALASSEMIA

A. Matte'[1], M. Winter[2], E. Beneduce[1], E. Federti[1], A. Siciliano[1], A. Macias-garcia[3], A. Iolascon[4], T. Singer[2], O. Khwaja[2], A. Korner[2], J.-J. Chen[3], A. Harmeier[2], C. Brugnara[5], L. De Franceschi[1,*]
[1]Medicine, University of Verona, Verona, Italy, [2]Pharmaceutical Research and Early Development, Hoffmann-La Roche , Basel, Switzerland, [3]MIT, MIT, Cambridge, United States, [4]Biotecnologie Avanzate-CEINGE, Federico II University, Naples, Italy, [5]Lab of Medicine, Children's hospital Harvard Medical School, Boston, United States

Background: The anemia of β-thalassemia is due to a combination of reduced red cell survival in the peripheral circulation and ineffective erythropoiesis, the latter due to unbalanced hemoglobin chain synthesis, and hemichrome-induced oxidative damage. Here we used a specific and selective inhibitor of the plasma membrane expressed glycine transporter GlyT1 (RO4917838) in a mouse model for β-thalassemia ($Hbb3^{th/+}$). A previous study in Wistar rats has shown that RO4917838 induces a dose-dependent decrease in MCH, Hb, soluble transferrin receptor, and increase in absolute reticulocytes and RBC counts (Winter *et al*. Exp Hematol, DOI: 10.1016/j.exphem.2016.07.003). This has been linked to the ability of RO4917838 to reduce glycine bioavailability in erythroblasts and decreased heme biosynthesis.
Aims: To evaluate the impact of the glycine transporter GlyT1 selective inhibitor RO4917838 on anemia of a mouse model for β-thalassemia.
Methods: Wild-type control (WT) C57B6/2J, and $Hbb^{th3/+}$ mice (β-Thal) aged between 3 to 4 months were treated daily with either vehicle or RO4917838 at dosages of 3, 10, 30 mg/kg/d for 4-6 weeks by gavage. Hematological parameters, analysis of erythropoiesis, molecular studies of sorted erythroid precursors, indices of hemolysis, hepcidin liver expression and Pearls staining were carried out.
Results: RO4917838 administration was associated with an improvement of β-Thal hematologic phenotype, as supported by (i) the amelioration of red cell morphology; (ii) the increase in Hb levels; (iii) the reduction in reticulocyte count

and in the percentage of circulating erythroblasts; (iv) the increase in β Thal red cell survival. RO4917838 induced a significant reduction in extramedullary erythropoiesis as well as in the amount of insoluble alpha chain aggregates in circulating red cells. It is of note that in β-Thal sorted erythroblasts we found a reduction in HRI and in phospho-eIF2a, indicting a reduction in free heme, which shall resulted in the activation of HRI, in RO4917838 treated β -Thal mice (10 mg/Kg/d, 6 weeks). Finally, in β-Thal mice treated with RO4917838 (4 weeks at 30 mg/kg/d) a reduction in liver and spleen iron-overload was identified, which was associated with increased hepcidin liver expression.
Summary/Conclusions: Our data suggest that RO4917838 ameliorates anemia and ineffective erythropoiesis by reduction of heme biosynthesis in a mouse model for β-thalassemia. RO4917838 is a potential, novel therapeutic approach for the treatment of anemia in patients affected by beta-thalassemia.

P393

MAY MUTATIONS IN THE KLF1 GENE HAVE WORSENING EFFECTS ON THE BETA THALASSEMIA PHENOTYPE?

M.R. Storino[1], M. Giuliano[1], G. Fioretti[2], S. Puzone[1], R. Sessa[1], L. Vicari[2], M.P. Ottaiano[1], M. Caldora[3], S. Costantini[4], C. Matarese[3], A. Sarappa[3], G. Amendola[5], A. Filosa[4], P. Izzo[1], M. Grosso[1,*]
[1]Dep. Molecular Medicine and Medical Biotechnology, University of Naples Federico II, [2]UOSC Genetica Medica, AORN A. Cardarelli, [3]UOC Patologia Clinica, P.O. Pellegrini, ASL NA1, [4]UOSD Malattie rare del globulo rosso, AORN A. Cardarelli, Naples, [5]UOC Pediatria-TIN, P.O. Umberto I, Nocera Inf. , Italy

Background: Kruppel-like factor 1 (KLF1) is a pleiotropic erythroid transcriptional factor that plays a key role in erythropoiesis (Siatecka M, Blood 2011; 118: 2044-521). Accordingly, KLF1 mutations have been found to be responsible for a variety of hematological disorders. KLF1 also contributes directly or indirectly to regulate the expression of genes in the beta-globin gene cluster and the fetal-to-adult globin gene switching (Waye JS et al Int. J. Lab. Hem. 2015; 37: 78-84). It has been reported that mutations leading to KLF1 haploinsufficiency are linked to increased fetal hemoglobin (HbF) levels with ameliorative effects on the severity of beta-thalassemia (Liu D. *et al.* Blood 2014; 124: 803-811; Perkins A. *et al.* Blood 2016; 127: 1856-1862).
Aims: This study was aimed at providing a functional characterization of known and novel mutations in the KLF1 gene associated with atypical beta-thalassemia phenotypes.
Methods: Hematological parameters were measured using an automated hematology analyzer (Beckman Coulter) and high performance liquid chromatography (Variant II, Bio-Rad Laboratories). Screening of KLF1 mutations was performed by Sanger sequencing on an Applied Biosystems 3730 DNA analyzer. Functional studies were performed by gene reporter assays and expression vectors for KLF1 mutants in the human K562 erythroleukemia cell line. This study was performed on 19 adult subjects, including 11 beta-thalassemia heterozygotes with an unexpected phenotype of intermediate thalassemia (moderate or severe anemia, elevated HbA_2 and/or HbF levels) and 8 subjects with normal erythrocyte indices and borderline HbA_2 and/or HbF levels without mutations in alpha- and beta-globin gene clusters.

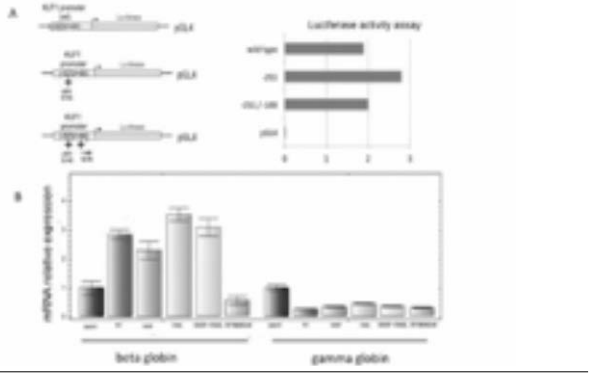

Figure 1.

Results: Of the 19 patients who were tested, 15 were found to be positive for mutations in the KLF1 gene. More in detail, we found 7 mutations, comprising a nucleotide variation (c.-251 C>G) already reported as a single nucleotide polymorphism and a known mutation (c.-148 G>A) in the proximal promoter region, 3 known mutations associated with increased HbA_2 and/or HbF levels (S102P, F182L and M39L) (Radmilovic M. *et al.* Ann. Hematol 2013; 92: 53-58) and two novel mutations (C94X and P173Pfs*236), all of them in the proline-rich domain in exon 2. Functional studies were performed in K562 cells in order to clarify the pathogenic significance of these mutations and to better define the role of KLF1 in atypical thalassemia phenotypes. Interestingly, the c.-251 C>G polymorphism was found to be associated with an increased transcriptional activity of the KLF1 promoter (Figure 1A), thus allowing us to exclude for this nucleotide variation the condition of a neutral polymorphism. Furthermore, unexpectedly, the novel P173Pfs*236 mutation was found to be associated with a dramatic reduction of the beta-globin gene expression levels (Figure 1B).
Summary/Conclusions: Our study confirmed the ameliorative effect of some KLF1 mutations on the thalassemia phenotype that were found to be associated with increased fetal- and/or beta-globin gene expression. In other cases we demonstrated that KLF1 mutations may contribute to worsen the beta thalassemia phenotype or result in a silent beta thalassemia trait. This study provides further insights into the multiple roles of KLF1 in erythropoiesis and highlights an intriguing effect of a subset of KLF1 mutations that may contribute to the severity of the thalassemia phenotype, thus reinforcing the relevant implications of KLF1 screening for genetic counseling and for effectiveness of prevention screening programs for hemoglobinopathies.

P394

SECONDARY SOLID TUMORS FOLLOWING HEMATOPOIETIC CELL TRANSPLANTATION FOR THALASSEMIA MAJOR

A. Meloni[1,*], A. Natale[2], S. Santarone[2], M. Di Ianni[3], S. Angelini[4], L. Pistoia[1], L. Cuccia[5], A. Spasiano[6], A. Pepe[1], P. Di Bartolomeo[2]
[1]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Bone Marrow Transplant Center, Pescara, [3]University of L'Aquila, L'Aquila, [4]Tor Vergata University, Roma, [5]ARNAS Civico "Benfratelli-Di Cristina", Palermo, [6]AORN A. Cardarelli, Napoli, Italy

Background: Secondary solid tumors (SST) have been described after HCT, in particular for patients affected by hematologic malignancies. There is limited information about the incidence of SST following HCT for thalassemia major (TM).
Aims: The aim of this study was to determine the incidence of SST in 134 patients with TM who received HCT in our Center between 1983 and 2013
Methods: 117 patients survived more than 3 years after HCT and were enrolled in the study. Of them, 57 were males and 60 females. Their median age at time of HCT was 10 years (1-29). As conditioning regimen, they received Busulfan (14 mg/Kg) and Cyclophosphamide (200 mg/Kg). The GvHD prophylaxis included Cyclosporine and Methotrexate. All patients received bone marrow cells from an HLA identical donor.
Results: At time of this report, 112 patients were cured, whereas 5 patients rejected their graft and are now under regular transfusion treatment.
Overall, the median follow-up after HCT was 24 years (3-34). Seven patients developed a malignancy 3.2 to 28 years (median 16,4 years) after HCT including 2 carcinomas of the tongue, 1 oral squamous cell carcinoma, 1 colorectal cancer, 1 thyroid carcinoma, 1 carcinoma of the uterine cervix, and 1 parotid carcinoma. The 30-yr cumulative incidence (CI) of developing SST was 10±0.17%. All patients underwent surgical resection of the tumor and in addition 4 of them received chemotherapy and/or radiotherapy. Of relevance, the 3 patients with cancer of the oral cavity were affected by severe chronic GvHD with buccal cavity involvement. Two patients (1 with parotid and 1 with tongue carcinoma) died of tumor progression and 5 are living. We compared these results with 2 case control populations. First of all, we investigated the occurrence of solid tumors in the 117 individuals (64 males, median age 10 years at time of marrow donation), who served as stem cell donors for HCT. One donor developed breast cancer 29 years after marrow donation at age of 38. The 30-yr CI of developing solid tumor for donors was 4.5±0.21% with a statistically significant difference (p=0.03) as compared to that of transplanted patients. The second case control population consisted of 117 patients affected by TM treated with transfusions and iron chelation. The matching technique applied was based on the variables age and sex. One control per case (transplanted patient) was randomly selected from the MIOT (Myocardial Iron Overload in Thalassemia) registry and matched by sex and age with the transplanted patient population. Two patients developed an hepatocellular carcinoma (HCC) at age of 39 and 44 years, respectively. One patient died and one is living. Using the event rate measure, we observed an event rate of 0.102 at 30 years for the transplant group and 0.041 for the nontransplant group (p=0.106).
Summary/Conclusions: This study shows that the magnitude of increased risk of SST is twofold to threefold for patients treated with HCT as compared with an age- and sex matched nontransplant TM patients or with stem cell donors. Notably, among the transplanted patients we didn't observe any case of HCC, which is one of the most frequent solid tumor in nontransplant TM patients, whereas we observed 4 cases of head/neck cancers. In our series, cGvHD seems to be a strong risk factor in the development of new solid tumors. Patients with cGvHD, especially those with involvement of the oral cavity, must receive a very long careful monitoring and surveillance in order to prevent the development of secondary cancers.

P395

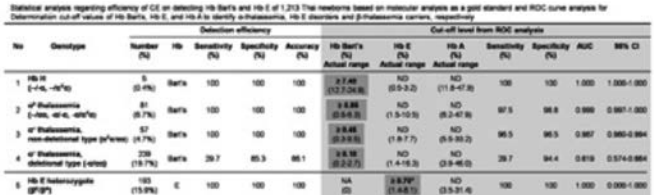
VALIDATING A NOVEL CAPILLARY ELECTROPHORESIS: THE MOST SUITABLE PLATFORM FOR THE NATIONAL NEWBORN SCREENING PROGRAM IN A REGION WITH HIGH PREVALENCE OF THALASSEMIA AND HEMOGLOBINOPATHIES

T. Suksangpleng[1,*], S. Riolueang[1], J. Korchuenjit[1], W. Korchuenjit[1], J. Pooliam[2], V. Viprakasit[1,3]

[1]Thalassemia Center, [2]Clinical Epidemiological Unit, Office for Research and Development, [3]Division of Hematology/Oncology, Department of Pediatrics, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Newborn screening program for thalassemia (thal) and hemoglobinopathies (NBS-Hbs) is crucial for early detecting patients with serious hemoglobinopathies (Hb variants) *e.g.* Sickle cell anemia (Hb SS). NBS-Hbs has been incorporated into a routine neonatal service in several developed countries. However its role on early detection other forms of globin disorders remains unclear. Moreover, NBS-Hbs can detect several types of thalassemia and Hb variants carriers. This application could be useful for the national prevention and control program for severe thalassemia syndromes in many developing countries including Thailand where these conditions are highly prevalent especially β-thal major, Hb E/β-thal and Hb Bart's hydrops fetalis (caused by α^0-thalassemia). Recently a new capillary electrophoresis (CE) has been developed specifically for NBS-Hbs. However there is a limited data on validation of this technology on detecting several types of thalassemia and Hb variants found in Southeast Asia.
Aims: To evaluate and validate a new CE system to screen globin disorders in newborn to initiate the national NBS-Hbs for Thailand
Methods: After informed consent, 1,213 blood samples of 2-day old newborns were collected by heel prick puncture into 5-dried blood spots. After elution, dried blood samples were analyzed by Capillarys 2 NEONAT FAST® (SEBIA, Évry, France). All samples were also extracted for DNA and genotyped by our extensive PCR based panel to detect >98% of abnormal globin alleles found in Thailand using α-thal GAP-PCR, α-thal ARMS-PCR, β-thal ARMS-PCR, and PCR-RFLP for Hb E. We compared CE data with each globin genotypes and use a ROC curve to set up new diagnostic criteria using% Hbs from CE for future cases.
Results: Identification of Hb Bart's provided 100% of sensitivity, specificity and accuracy in most individuals with α-thal. Using ROC analysis, we proposed different cut-off values of Hb Bart's to differentiate Hb H disease, α^0-thal and non-deletional α^+-thal traits; ≥7.40%, ≥0.85%, ≥0.45%, respectively with excellent accuracy (Table 1). Interaction of Hb E with these α-thal genotypes has no effect on these cut-off values (Table 1). However, there was a limitation to identify deletional α^+-thal trait using CE by the level of Hb Bart's ≥0.10% (detectable level). A cut-off level to distinguish Hb EE from Hb E trait was suggested at ≥4.95% *vs* ≥0.7%. Two patients with Hb E/β-thalassemia were identified through this study with different CE pattern from Hb EE. 11 β-thalassemia traits was identified and they had a lower level of Hb A as compared to their gestational age (GA)-sex matched controls with normal β globin genotypes (n=148). We recommend Hb A level ≤10.35%; a cut-off to primarily consider for β-thalassemia carrier followed by molecular analysis.

Table 1.



Summary/Conclusions: This newborn CE platform showed a high efficiency for detecting several types of thalassemia and Hb variants in particular α-thal, β-thal and Hb E using cut-off levels of each Hb species described herein. Besides early detecting of Hb S, we can now apply this NBS into a routine service in order to early detect Hb H disease, Hb E/β thalassemia and the majority of common thalassemia carriers. This NBS-Hbs approach can reinforce and leverage our current program on prevention and control for severe thalassemia syndromes in our region. Moreover, due to population migration from The East to the West, our new diagnostic guideline by CE could be useful and applicable for existing NBS programs currently available in several European countries.

P396

TRANSIENT ELASTOGRAPHY IN NON TRANSFUSION DEPENDENT THALASSEMIA: A SUCCESSFUL TOOL TO ASSESS AND MONITORING LIVER FIBROSIS

A. Marcon[1,*], G. Graziadei[1], M. Pennisi[1], M. Migone De Amicis[1], M. Fraquelli[2], M.D. Cappellini[3]
[1]Rare Diseases Center, Department of Medicine and Medical Specialities, Foundation IRCCS "Ca' Granda" Ospedale Maggiore Policlinico, [2]Department of Pathophysiology and Organ Transplantation, [3]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy

Background: Non Transfusion Dependent Thalassemia (NTDT) patients are at risk for several complications due to chronic anemia, hypoxia and iron overload. Over the recent years hepatic complications are more frequently observed in these patients probably due to the aging and poor care: monitoring liver fibrosis is becoming part of the follow up. Liver stiffness measurement (LSM) by transient elastography (TE), a widely-used non-invasive tool, in our centre has been included in the regular follow-up of patients with NTDT
Aims: To evaluate by TE liver fibrosis in NTDT patients, its correlation with biochemical, hematological and clinical parameters at baseline and after 5 years
Methods: Hepatic fibrosis and siderosis were evaluated in 101 NTDT patients using respectively TE, and liver iron concentration (LIC) derived from T2* Magnetic Resonance Imaging (MRI) at baseline and, in a subset of patients, after 5 years. The following TE thresholds were taken into account: <5.0 kPa no fibrosis (F0), 5.1-7.9 kPa mild fibrosis (F1), >7.9 kPa moderate fibrosis (F2), >10.3 advanced fibrosis (F3), >11.9 kPa cirrhosis (F4). Biochemical and hematological blood test were collected too. Patients were also tested for HCV antibodies and HCV RNA. Data were analyzed retrospectively
Results: Patient's mean age was 46±11 years, 37/101 (36.6%) were splenectomized, 51/101 (50.5%) had never been transfused, 46/101 (45.5%) were occasionally transfused and 4/101 (3.9%) had been regularly transfused for 10+5yrs. At baseline (T0), the overall mean LSM was 5.9 ±2.6 kPa, mean LIC 6.68±5.37 mg/g dw, ferritin 700±596 ng/ml, Hb 9.3±1.3 g/dl, AST, ALT GGT and ALP were normal. LSM correlate with GGT (p <0.001) and AST values (p=0.02). Seven/101 (6.9%) patients were HCV RNA positive, one of them had never been transfused. At baseline 37/101 (36.6%) patients were on iron chelation (ICT) (29 deferoxamine, 7 deferasirox, 1 deferiprone). At T0 patients with fibrosis (any grade) didn't show differences compared with patients without fibrosis (F0) regarding age, splenectomy, transfusions, ICT and all biochemical tests except for GGT (mean GGT 16.1 ± 10.9 U/L in F0 group, GGT 27.1 ± 24.8 U/L in patients with any grade of fibrosis, p <0.05). For 60 patients data at 5±1 years (T1) were available. LSM remained stable in 35/60 (58.3%): 24 patients did not show fibrosis in both T0 and T1 evaluations, 10 patients showed a F1 fibrosis in both evaluations and one remained in the F4 class. Among these patients 13/35 (37.1%) were on ICT. A reduction in LSM was found in 21/60 (35%) patients (T0=7.09±1.63 kPa, T1=5.07±1.61 kPa, p<0.001), with a reduction trend in LIC (T0 =6.79±4.09 mg/g dw, T1=5.18±3.04 mg/g dw; p=0.09 ns) and a statistical significant reduction in ferritin levels (T0=709±458 ng/ml, T1 436±280 ng/ml, p=0.005); 14/21 (66.6%) were on ICT. Comparing patients who remained stable with patients who ameliorate the grade of fibrosis, a significant difference was found regarding the number of patients on ICT (37.1% *vs* 66.6% respectively, p <0.05). A worsening in LSM was observed in 4/60 (6.6%) patients: among them LSM changed from F0 to F1 in 2 patients, and from F2 to F4 in the other 2 patients. None of these patients presented HCV RNA positivity
Summary/Conclusions: NTDT patients could benefit from regular non-invasive assessment of liver fibrosis. In our study subject who received ICT had best chance to reduce the grade of fibrosis through the reduction in iron overload. In these patients, that usually are HCV RNA negatives, monitoring and treating iron overload is a crucial point in the prevention of hepatic fibrosis being the hepatic siderosis the primary cause of hepatic tissue damage, cirrhosis and hepatocellular carcinoma.

P397

INCREASING INCIDENCE OF MALIGNACIES IN AGING THALASSEMIC PATIENTS: A SINGLE INSTITUTION'S LONGITUDINAL EXPERIENCE

E. Repousi[1,*], M. Moraki[1], D. Kyriakopoulou[1], P. Delaporta[1], A. Kafourou[1], A. Kattamis[1]
[1]Thalassemia Unit,First Department of Pediatrics, National and Kapodistrian University of Athens, 'Aghia Sophia' Children's Hospital, Athens, Greece

Background: The introduction of close monitoring, regular blood transfusions and systematic iron chelation in the management of thalassemia have significantly changed the clinical phenotype of the patients and improved their survival. The patients, who have benefited of the current therapeutic regimen, are now reaching middle age, and they have started facing problems more commonly seen in older people. Recent observations suggest of an increased incidence of malignancies in the aging group of thalassemic patients.
Aims: The purpose of this study is to determine the longitudinal changes in the incidence of malignancies, along with possible correlations to different aspects of the disease.
Methods: A retrospective study in the largest Thalassemia Unit in Greece has been conducted spanning an observation period from 2001-2016. The occurrence and type of cancer, as well as history on transfusion dependence, liver failure, HCV infection and chelation therapy were recorded and analyzed. Statistical analysis was performed with SPSS software package, v. 20. A p-value<0.05 was considered statistically significant.
Results: Records from 591 patients (338 with thalassemia major and 253 with thalassemia intermedia) were evaluated. 27 patients (11 males and 16 females)

with malignancies were identified (incidence: 4.6%). The mean age of the diagnosis of the malignancy was 41.6 years (36.6 years for thyroid gland cancer, 45.8 years for liver, 38 years for hematologic malignancies and 46 for renal cancer). 24 patients were transfusion dependent (TD) (7% of the patients) and 3 non transfusion dependent (1.18%). Liver cancer had the highest incidence 29.6%, following by thyroid gland cancer 25.9%, hematologic malignancies 11.1% and renal cancer 14.8%. HCV infection was found in 56.7% of the patients and a statistical significant relationship between HCV infection and cancer (p=0.001) was detected. No correlation between liver failure and cancer was detected. In the TD group, the age specific ratio of cancer increased with age with the patients >50 years having the highest ratio of 42.3, compared to 36.9 and 17.1 observed in the 46-50 years and 41-45 years age groups, respectively. In regards to chelation therapy, at the time of diagnosis 40.9% of the patients were receiving deferasirox (DFX), 22.7% deferiprone (DFP), 22.7% deferoxamine (DFO), 9.1% no chelation therapy and 4.5% DFO/DFP. No statistical significant difference was observed between the different chelation therapies (p=0.119). As the utilization of different types of chelation changed throughout the years, according to the availability of the chelating agents, we analyzed separately, the patients that developed malignancies in the period after 2010 when longitudinal exposure to all three chelators can be assumed. Even though the results showed a difference (p=0.027) between the different groups with 47.1% of those patients receiving DFX at the time of the diagnosis compared to 27.1% receiving DFP and to 11.8% receiving DFO, this distribution reflects the overall distribution of chelator usage during that period. Apart from the incidence, there was no statistical significant difference between TD and NTD patients with cancer regarding the gender, age and year of diagnosis. The mean cancer mortality rate was 48%, but varied significantly with the type of cancer with liver cancer and hematological malignancies having a mortality of 66% .Overall only 2% of the deaths occurring in our group of patients were attributed to cancer.

Summary/Conclusions: This retrospective study has confirmed the increased incidence of malignancies in thalassemia patients in Greece, which is, at least, partially related to the aging of this population. Based on these observations, adaptation of monitoring guidelines is essential for optimal management of thalassemic patients. Periodic screening for malignancies, especially hepatic, thyroid and hematologic, will allow early detection and timely, and thus, more efficacious treatment of the neoplasia.

P398

SAFETY AND EFFICACY OF EARLY START WITH SUBOPTIMAL DOSE OF DEFERIPRONE IN MINIMALLY TRANSFUSED INFANTS WITH TRANSFUSION DEPENDENT THALASSEMIA: A RANDOMIZED TRIAL

M. Elalfy[1,*], B. Helal[2], V. Berdoukas[3], F. Tricta[4], M. Tarif[1], H. Awad[5], A. Adly[1]
[1]AinShams university, [2]Ain Shams University, Cairo, Egypt, [3]3 Oasis International Hospital, Beijing, China, Beijing, China, [4]4 ApoPharma Inc., Toronto, Canada, [5]National Research Center, Cairo, Egypt

Background: Early exposure to Iron toxicity is the main risk factor for morbidity and mortality in patients with transfusion-dependent thalassemia. Current practice is to start chelation therapy only after 10-20 transfusions, or when the serum ferritin (SF) level rises above 1,000 µg/L.

Aims: To evaluate the safety and efficacy of the early use of low-dose deferiprone in minimally transfused pediatric thalassemia patients and to evaluate if it can postpone iron overload in these group of patients.

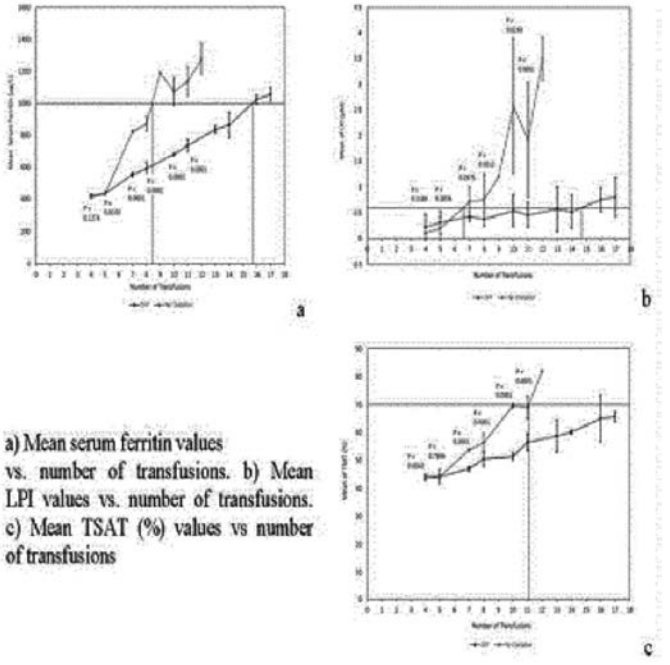
Methods: In the current trial (ClinicalTrials.gov Identifier: NCT02173951), sixty-four children recently diagnosed with thalassemia major who had begun receiving blood transfusions in first year of life to keep pre-transfusion Hb above 10 gm/dl, had not yet started iron chelation therapy and had SF ≥400 µg/L or transferrin saturation (TSAT) ≥70% or labile plasma iron (LPI) ≥0.2 µM were randomized to start deferiprone (DFP) at a sub-therapeutic dose (50 mg/kg/day) or no chelation (NC). Median age at 1st transfusion was 8 months for both DFP-treated and for NC children. The percentage of patients with LPI ≥0.6 µM, SF ≥1000 µg/L or TSAT ≥70% in each study arm was assessed at 6, 9 and 12 months (patients confirmed SF ≥1000 ng/mL were withdrawn from the study and placed on a standard chelation regimen). Complete blood count was done weekly in DFP treated and every 3-4 weeks in NC.

Results: Table 1. Summary of the efficacy results of SF, TSAT, and LPI.

Table 1.

	Baseline		3 months		6 month		9 months		12 months	
	ES-DFP	DC	ES-DFP	DC	ES-DFP	DC	ES-DFP	DC	ES-DFP	DC
SF (µg/L)	431±14 N=32	430±15 N=32	579±36 N=30	862±44 N=31	708±33 N=25	1110±77 N=31	861±68 N=30	1274±89 N=29	1042±40 N=27	
% patients with SF ≥ 1000 µg/L	0%	0%	0%	3%	0%	100%	10%	100%	100%	
TSAT (%)	44.0±0.9 N=31	44.4±2.4 N=31	49.2±2.7 N=27	55.9±3.2 N=28	54.0 ± 2.9 N=25	69.1±3.6 N=26	59.8±3.8 N=25	82.0 N=1	65.4±5.8 N=23	
% patients with TSAT ≥ 70%	0%	0%	0%	0%	0%	54%	0%	100%	26%	
LPI (µM)	0.28±0.2 3 N=31	0.18±0.2 0 N=31	0.40±0.1 3 N=30	0.75±0.4 8 N=31	0.50±0.2 7 N=30	2.00±1.1 4 N=31	0.54±0.3 6 N=28	3.50±0.4 2 N=2	0.79±0.3 2 N=24	

All NC patients were removed from the trial prior to completing 7 months of follow-up (9-11 transfusions) due to confirmed SF ≥1000 µg/L. Mean ± SD time of follow up was 10.4± 4.9 and 5.9 ± 2.5 months for DFP and NC respectively. Most common adverse events in patients on DFP *versus* NC were diarrhoea (19% *vs* 13%, p= 0.73), vomiting (13% *vs* 13%, p=1.00), abdominal colic (13% *vs* 13%), elevated liver enzymes (6% *vs* 3%, p=1.00) and neutropenia (6% *vs* 6%). All adverse events were mild in severity and did not require interruption of DFP use. There were no cases of agranulocytosis or moderate neutropenia, no arthralgia and no serious infections in DFP-treated patients. DFP therapy was associated with a significant reduction in the rate of iron accumulation as measured by SF (P<0.0001), LPI (P<0.001)and TSAT (P<0.001) (Figure 1a, b, c). LPI ≥0.6 µM appeared as early as after 5 transfusions in NC children and was delayed to at least 10 transfusions with DFP therapy. TSAT ≥70% appeared after 10 transfusions in NC children and was delayed to at least 17 transfusions with DFP therapy.The results of this study show that LPI and TSAT may reach values ≥0.6 µM and ≥70%, respectively, after 5 -10 transfusions in children with TM and all NC children had *SF ≥1000* µg/L after 8-9 transfusions.



a) Mean serum ferritin values vs. number of transfusions. b) Mean LPI values vs. number of transfusions. c) Mean TSAT (%) values vs number of transfusions

Figure 1.

Summary/Conclusions: A sub-therapeutic dose of deferiprone for a mean of 12 months in children with TM and low iron overload was not associated with safety concerns and able to significantly reduce the rate of iron accumulation as measured by SF , LPI and TSAT.

P399

LONGITUDINAL PROSPECTIVE MRI STUDY IN PEDIATRIC PATIENTS WITH THALASSEMIA MAJOR

M. Casale[1,*], A. Meloni[2], A. Filosa[1], L. Pistoia[2], F. Sorrentino[3], A. Quarta[4], A. Carollo[5], M. C. Cirotto[6], V. Positano[2], E. Grassedonio[7], M. Missere[8], A. Pepe[2]
[1]AORN A. Cardarelli, Napoli, [2]Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [3]Ospedale "Sant'Eugenio", Roma, [4]Ospedale "A. Perrino", Brindisi, [5]Azienda Ospedaliera "Sant'Antonio Abate", Trapani, [6]ASL N°1 Sassari, Sassari, [7]Policlinico "Paolo Giaccone", Palermo, [8]Fondazione di Ricerca e Cura "Giovanni Paolo II", Campobasso, Italy

Background: No studies are available in literature evaluating, on repeated magnetic resonance (MRI) imaging assessments, changes in myocardial and hepatic iron overload, biventricular function, and development of macroscopic myocardial fibrosis in pediatric patients with thalassemia major (TM)

Aims: This is the first longitudinal prospective MRI study in pediatric TM patients.

Methods: We considered 68 TM patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) project with less than 18 years at the first MRI scan and who performed a follow-up (FU) study at 18±3 months.
Myocardial and hepatic iron burdens were quantified by the T2* technique. Atrial dimensions and biventricular function were quantified by cine images. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.

Results: At the baseline MRI, 16 (23.5%) patients showed myocardial iron overload (MIO; global heart T2*<20 ms) and 54 patients liver iron overload

(79%). Figure 1 shows the changes in iron levels. Twenty-five patients changed the chelation regimen after the baseline MRI. Globally, a worsening in cardiac iron was found in the 3% of the patients while a worsening in hepatic iron in the 21% of the patients (P=0.003). The LV end-diastolic volume index and all RV volumes as well as the LV mass index were significantly lower at the FU MRI. No significant improvement in left or right global systolic function was found. For 40 patients the presence of myocardial fibrosis was investigated at both baseline and FU scans. Six patients (15.0%) had myocardial fibrosis at the baseline MRI and myocardial fibrosis was detected for all of them also at the FU. The extent of myocardial fibrosis was comparable between the two scans (0.77±0.42% *vs* 0.79±0.51%; P=0.686). At the FU 4 new occurrences of myocardial fibrosis were detected. In patients with baseline MIO no significant correlation was found between the percentage change in cardiac iron and the changes in hepatic iron or the baseline hepatic iron.

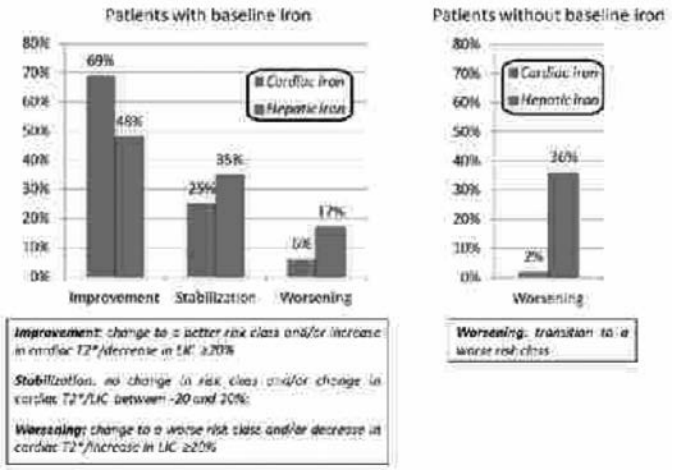


Figure 1.

Summary/Conclusions: Magnetic resonance monitoring in children with TM demonstrated a good control of cardiac iron overload in terms of prevention and treatment but the need for further improvement of liver iron overload. Myocardial fibrosis appears mainly multifocal, non progressive and not reversible over a 18- month period. A prompt and aggressive approach to iron overload and a chelation regimen consistent with the high iron intake and the high rate of severe liver iron overload is recommended in children.

P400

LONG TERM FOLLOW-UP OF A COHORT OF WELL TREATED B-THALASSEMIA MAJOR PATIENTS BY MULTI-ORGAN R2* MAGNETIC RESONANCE IMAGING

V.M. Pinto[1], L. Bacigalupo[2], B. Gianesin[1], M. Balocco[1], M. Lamagna[1], S. Quintino[1], G.L. Forni[1,*]
[1]Haematology-Centro Microcitemia Anemie Congenite, [2]Radiology Unit, Ospedale Galliera Genova, Genova, Italy

Background: The introduction of non-invasive multi-organ evaluation of iron overload by R2* Magnetic Resonance Imaging (MRI) in β-thalassemia major (TM) patients has improved the patient care allowing a more careful tailoring of iron chelation therapy.
Aims: We report a cross-sectional and longitudinal experience with the use of MRI-R2* heart, liver and pancreas in a cohort of well treated TM patients.
Methods: TM patients underwent contemporaneous assessment of pancreatic, cardiac and hepatic MRI-R2* (1.5 T GE HDx scanner) in the period Jan08-Dec16.
Results: 69 TM patients: 43% male, age 38±9yrs, median number of observations/patient 6 (IQR:5-7), median number of yrs of the follow-up (f.u.) 8 (IQR:7-8). Iron chelation regimens included deferiprone (basal 30%>f.u.32%), deferasirox (basal 45%>f.u.52%), daily alternating deferasirox+deferiprone (basal 3% -f.u.6%), deferoxamine (basal 9%>f.u.6%) deferoxamine+ deferiprone (basal 13%>f.u.4%). The observation at the baseline showed a positive strong correlation between R2* values of pancreas and both of liver (R_p=0.68, p<0.001) and heart (R_p=0.75, p<0.001), in accordance with literature. Moreover, the ROC analysis confirms the value of 100 Hz for the pancreatic-R2* as the predictor of cardiac R2*>50Hz (*Noetzli et al. Blood 2009*). We observed a significative correlation of ferritin values with R2* of liver (R_p=0.53,p<0.001), heart (R_p=0.24, p=0.04) and pancreas (R_p=0.35,p=0.003). At f.u. the number of cases of moderate/severe iron overload decreases in the liver (from 11 to 0), in the heart (from 14 to 2) and in the pancreas (from 27 to 23) and the correlation of R2* of pancreas with R2* of heart (R_p=0.25, p=0.034) and liver (R_p=0.42, p<0.001) is weaker in respect to the baseline. We observed a significative decrease of R2* values both in the liver (p=0.0012), heart (p=0.017) and pancreas (p=0.018). Once again we found a correlation between the values of ferritin and R2* of liver (R_p=0.37,p=0.0015), heart (R_p=0.26, p=0.028) and pancreas (R_p=0.23,p=0.05). Moreover the variations of ferritin correlate with the variations of R2* of the liver (R_p=0.6,p<0.001), heart (R_p=0.25, p=0.04) and pancreas (R_p=0.41,p= p<0.001). Finally, assuming the cutoff value of 100 Hz for the pancreatic-R2* as the predictor of a cardiac R2*>50Hz, we calculated the numbers of false/true positive/negative according to the rule above. At the baseline we can observe that the number of false positive is the 14/27 (52%). The percentage increases to 91% (21/23) after f.u.: the pancreas-R2*>100Hz in 23 patients but only 2 has iron overload in the heart; the total number of patients with pancreatic-R2*>100Hz is quite the same before and after f.u. (27 compared to 23). We found no correlation between the false positive predicted and particular conditions such as impaired glucose tolerance, diabetes or adipose involution (Table 1).

Table 1.

(A) Multi-organ MRI-R2*evaluations at baseline and at f.u.. (B) Ability of pancreatic-R2* to predict cardiac iron (R2*>50Hz): counts of False/True positive and False/True negative.

(A)	*MRI-R2* and iron overload at baseline and f.u.*									
	Heart		*Liver*					*Pancreas*		
BASELINE	R2* (Hz)	> 50 Hz	R2* (Hz)	Severe	Mod.	Mild	None	R2* (Hz)	> 50 Hz	> 100 Hz
	27 (IQR: 24-41)	14	119 (IQR: 73-253)	3	8	18	40	86 (IQR:63-122)	56	27
F.U.	26 (IQR: 23-30)	2	99 (IQR:46-159)	0	0	18	51	76 (IQR: 48-119)	51	23

(B)	*Ability of pancreatic-R2* to predict cardiac iron (R2*>50Hz)*			
	False Positive	*True Positive*	*True Negative*	*False Negative*
BASELINE	14	13	41	1
F.U.	21	2	46	0

Summary/Conclusions: In this experience we observed that the regular multi-organ assessment of iron overload by R2* is concomitant with a reduction of the iron burden in this cohort of well treated patients confirming that is a careful method to tailoring the iron chelation therapy. However pancreatic-R2* remains above the cut-off for the prediction of cardiac iron overload, so this parameter should be considered with caution in the tuning of the chelation therapy, in order to avoid over-chelation risk. Ferritin values trend agree with R2* values confirming the reliability of this parameter. These results were obtained with a prevalent use of oral chelation regiment (90% of patients).

P401

DEVELOPMENT OF HTLV-1 HYPERIMMUNE GLOBULINS AGAINST HTLV-1 INFECTION

T. Mizukami[1,*], K. Nojima[1], R. Sobata[2], W. Kuribayashi[3], C. Matsumoto[2], Y. Sato[1], E. Sasaki[1], K. Furuhata[1], Y. Hiradate[1], K. Ohkuma[1], S. Matsuoka[1], M. Satake[1], I. Hamaguchi[1]
[1]Department of Safety Research on Blood and Biologicals, National Institute of Infectious Diseases, [2]Central Blood Institute, Japanese Red Cross, [3]Department of Cellular and Molecular Medicine, Graduate School of Medicine, Chiba University, Tokyo, Japan

Background: Adult T-cell leukemia (ATL) is a malignant disease caused by infection with human T-lymphotropic virus (HTLV-1). The prevention of HTLV-1 infection is the most effective strategy to eradicate ATL. However, there is no effective vaccine or anti-viral agent for HTLV-1.
Aims: The aim of this study was to develop an effective HTLV-1 hyperimmune globulin (HTLV-IG) isolated from HTLV-1 positive carriers screened at the Japanese Red Cross.
Methods: We developed two *in vitro* and *in vivo* screening methods to evaluate and characterize the anti-viral effect of HTLV-1 positive plasma and HTLV-IG.
Results: HTLV-1 positive plasma isolated from an HTLV-1 carrier with a proviral load (PVL) >4 inhibited both HTLV-1 infection and syncytia formation. We purified HTLV-IG from the HTLV-1 positive plasma (PVL >4) and evaluated its effect in a humanized mouse model. NOG (NOD.Cg-Prkdcscid Il2rgtm1Sug/Jic) mice were treated with HTLV-IG for 5 days before HTLV-1 infection. During the monitoring period up to 40 days after post-infection, HTLV-1 infection was observed in untreated infected mice, but not in HTLV-IG-treated mice. The inhibitory effect of HTLV-IG was observed at the early stage of HTLV-1 Infection. Treatment with HTLV-IG at 20 days after HTLV-1 infection had a partial inhibitory effect. HTLV-1 gp46 expression in HTLV-1 infected cells was slightly reduced and the localization of these cells was changed in each tissue after the first line of treatment. These data suggest HTLV-IG is effective at the early phase of HTLV-1 infection. We also assessed the viral safety of HTLV-1 during the HTLV-IG manufacturing process. High log reduction values of HTLV-1 were observed during the Cohn fractionation process. Virus safety was assessed by PCR based assay and *in vitro* and *in vivo* infection assays. We next assess the viral safety of HTLV-1 during the HTLV-IG manufacturing process. High log reduction values of HTLV-1 can be seen during the Cohn fractionation process. Virus safety was assessed with PCR based assay and *in vitro* and vivo infection assay.
Summary/Conclusions: These data suggest HTLV-IG is effective and safe for the prevention of HTLV-1 infection.

P402

THE CONTAMINATION OF TUMOR CELLS IN THE APHERESIS MATERIAL DOES NOT PREDICT THE RESPONSE OF MULTIPLE MYELOMA PATIENTS TO AUTOLOGOUS TRANSPLANTATION

M.L. Lozano[1,*], F. De Arriba[1], M. Sola[1], A. Sanchez-Fuentes[1], N. Revilla[1], F. Ortuno[1], A. Jerez[1], I. Heras[1], P. Iniesta[1], O. Lopez-Godino[1], M.D. Garcia-Malo[1], V. Vicente[1]
[1]Hematology and Clinical Oncology. Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, CB15/00055-CIBERER, Murcia, Spain

Background: The use of high dose of chemotherapy followed by autologous stem cell transplantation (ASCT) has improved the prognosis of patients with multiple myeloma (MM) and plasma cell dyscrasia. However, there is controversy over the effect of infusion of atypical plasma cells (PC) on the apheresis product.
Aims: To analyze whether in MM malignant plasma cell reinfusion could negatively affect responses to ASCT.
Methods: Patients (n=114) undergoing ASCT (n=120) for MM between June 2003 and February 2016 were enrolled in a retrospective study to analyze the prognostic value of aberrant (CD38++CD138+CD19-CD45weak) to normal phenotype (CD38++CD138+CD19+CD45+) plasma cells (A:T PC ratio) in the autograft by flow cytometry. The Durie-Salmon stage at diagnosis, response of disease to induction treatment, biological parameters, pre-ASCT percentage of PC in bone marrow and at day +100, and the mobilization scheme were determined. Response was assessed at day +100 after ASCT using the 2006 International Myeloma Working Group uniform response criteria. Data were analyzed with SPSS v20.
Results: Patient characteristics are shown in Table 1. Patients with a better pre-ASCT response to induction therapy (complete response [CR] or very good partial response [VGPR]) had a non-significant different median A:T PC ratio content in the apheresis material, than those with a poorer response (partial response [PR], stable [SD] or progressive disease [PD]), (0.4 *vs* 1, p=0.28). Similarly, a non-significant difference (p=0.251) was observed in the number of atypical PC contained in the autograft of patients with a better *vs* poorer pre-ASCT response (0.06 *vs* 0.08 ×10^6/kg). There was no difference between the type of mobilization (G-CSF *vs* chemotherapy+G-CSF) and the degree of apheresis contamination (median A:T PC ratio 0.5 *vs* 0.8; P=0.86). There was a statistical trend between the degree of infiltration of PC in the bone marrow before ASCT and the detection of atypical PC in the graft (p=0.06). At day +100, 94% of patients with CR or VGPR to induction therapy maintained the response, and 49% of patients in PR, SD or PD achieved post-ASCT CR or VGPR (p=1.24^-7). There was no association between the content of atypical PC in the graft and the response to day +100. However, the percentage of pre-ASCT PC in the bone marrow was significantly related to the response at day +100 (CR or VGPR *vs* PR, SD or PD), p=0.003, as well as the pre-ASCT monoclonal component (p=4.03^-7).

Table 1.

Median age, yr (range)	60 (30-70)
Male (%)	55 (45.8)
Plasma cell dyscrasia, n (%)	
- Multiple myeloma, IgG	66 (55.0)
- Multiple myeloma, IgA	28 (23.3)
- Bence-Jones multiple myeloma	15 (12.5)
- Plasma cell leukemia	5 (4.2)
- Other: Non secretory o plasmocytoma	6 (5.0)
Salmon-Durie staging, n (%)	
- Stage I	10 (8.3)
- Stage II	36 (30.0)
- Stage III	64 (53.3)
- Other (plasma cell leukemia or plasmacytoma)	10 (8.3)
Response to induction treatment before ASCT, n (%)	
- Complete response	36 (30.0)
- Very good partial response	19 (15.8)
- Partial response	55 (45.8)
- Stable disease	9 (7.5)
- Progressive disease	1 (0.8)
Mobilization regimen, n (%)	
- G-CSF	87 (72.5)
- Chemotherapy and G-CSF	33 (27.5)

Summary/Conclusions: Infusion of PC with atypical phenotype does not appear to affect the response at day+100 following ASCT, in patients with MM or plasma cell dyscrasia. Conversely, the quality of response to induction therapy was significantly associated to 100-day outcome after transplantation. These data support that *in vivo* persistent residual cells, but not those being infused with the graft, are the main source of relapse in MM.

P403

EVALUATION OF THERAPEUTIC PLASMA EXCHANGE AT A TERTIARY LONDON HOSPITAL

R. Moll[1,*], D. Warcel[1], S. Clark[1], M. Sekhar[1]
[1]Haematology, Royal Free Hospital , London, United Kingdom

Background: Therapeutic plasma exchange (TPE) is used to treat a number of haematological, renal and neurological conditions. Pathogenic antibodies or other plasma molecules are removed, and plasma volume is replaced with fluid. Human albumin solution (HAS) is usually preferred, except in cases of Thrombotic Thrombocytopenic Purpura (TTP) and related conditions. TPE may result in dilutional coagulopathy, and reactions such as hypersensitivity can occur. The British Society for Haematology (BSH) published a 2015 guideline to assist the use of TPE in UK clinical practice, providing evidence-based indications and recommended schedules.
Aims: To evaluate the use of elective TPE at a large tertiary London hospital, compare clinical practice against BSH guideline recommendations, and explore the effect of TPE on coagulation test results.
Methods: Data was collected prospectively over a 2 month period, using patient notes and electronic transfusion records. A data collection form recorded the indication, treatment schedule, replacement fluid, complications, the presence of a written treatment plan, and frequency and results of coagulation testing.
Results: 24 plasma exchanges took place over the period of data collection; there were no cases of TTP. Adherence to BSH guidelines was variable; although most cases (88%) had an evidence-based clinical indication for TPE, just 4% had a full written treatment plan, and only 17% of courses followed recommended scheduling. 75% of patients had received at least one prior course, some outside guideline indications for repeat courses. Most patients (83%) initially received appropriate replacement fluid (HAS), however 87% received FFP at some point during TPE, with 42% receiving Solvent Detergent FFP. In 17% of patients this fluid change was due to a reaction, but for the remainder it was due to dilutional coagulopathy. The guidelines recommend fibrinogen monitoring, and although most patients had baseline measurement (75%), subsequent testing showed wide variation. Despite this, 71% had a fibrinogen of ≤1 g/l measured during TPE. Fibrinogen levels showed some correction by the next day but usually still abnormal. A prolonged APTT and PT was also seen in most patients immediately following TPE, which almost always corrected by the next day.

Summary/Conclusions: TPE use was generally compliant with BSH guidelines regarding clinical indication and initial replacement fluid. However many patients were changed from HAS to FFP due to measured or predicted coagulopathy. This is a recognised complication of TPE, and the guidelines suggest that if possible, TPE can take place on alternate days to ameliorate this. Fluid change to FFP is recommended only for those at increased haemorrhagic risk. Almost all the TPE courses in our study took place over 3 to 5 subsequent days, reflected in the high frequency of hypofibrinogenemia. The optimum frequency of fibrinogen monitoring, and the level that should prompt change to the TPE schedule, require further exploration. The following are planned to enhance adherence to BSH guidelines and improve patient care: 1. Documented treatment plans with clinical indication, proposed treatment schedule, replacement fluid. 2. Local trust guidelines to include recommended TPE schedules, agreed parameters to monitor response, frequency of fibrinogen monitoring, common complications and their management. Where possible, TPE should take place on alternate days to reduce dilutional coagulopathy. 3. Education of staff involved with service provision, and strengthening of the role of apheresis nurse as lead.

P404

A COMPREHENSIVE PROTEOMICS STUDY ON PLATELET CONCENTRATES: PLATELET PROTEOME, STORAGE TIME AND MIRASOL PATHOGEN REDUCTION TECHNOLOGY

V. Salunkhe[1], F. van Alphen[2], I.M. De Cuyper[1], B. Nota[1], C. van der Zwaan[2], P.F. van der Meer[3], B.B. Daal[3], D. De Korte[3], A.B. Meijer[2], T.K. van den Berg[1], L. Gutierrez[4,*]
[1]Blood Cell Research, [2]Plasma Proteins, Sanquin Research, [3]Product and Process Development, Sanquin Blood Bank, Amsterdam, Netherlands, [4]Hematology, IdISSC, Madrid, Spain

Background: Platelet concentrates (PCs) represent a blood transfusion product with a major concern for safety as their storage temperature (20-24ºC) allows bacterial growth, and their maximum storage time period (less than a week) precludes complete microbiological testing. Pathogen reduction technologies (PRTs) provide an additional layer of safety to the blood transfusion products from known and unknown pathogens (such as bacteria, viruses and parasites). In this context, PRTs (such as Mirasol technology) have been developed and are implemented in many countries. However, several studies have shown *in vitro* that Mirasol PRT induces a certain level of platelet shape change, hyperactivation, basal degranulation and increased oxidative damage during storage. It has been suggested that Mirasol PRT might accelerate what has been described as the platelet storage lesion (PSL), but supportive molecular signatures have not been obtained.
Aims: We aimed at dissecting the influence of both variables, *i.e.* Mirasol PRT and storage time, at the proteome level.
Methods: We present comprehensive proteomics data analysis of control PCs and PCs treated with Mirasol PRT at storage day 2, 6 and 8. Our workflow was set to perform proteomics analysis using a gel-free and label-free quantification (LFQ) approach. Semi-quantification was based on LFQ signal intensities of identified proteins using MaxQuant/Perseus software platform.
Results: We identified marginal differences between Mirasol PRT and untreated PCs during storage. However, those significant changes at the proteome level were specifically related to the functional aspects previously described to affect platelets upon Mirasol PRT, and in addition, the effect of Mirasol PRT on the platelet proteome appeared not to be exclusively related to proteomic changes due to PSL.
Summary/Conclusions: In summary, semi-quantitative proteomics allows to discern between proteome changes due to Mirasol PRT or PSL, and proves to be a methodology suitable to phenotype platelets in an unbiased manner, in various physiological contexts.

P405

USE OF A SURVEY TO ASSESS AND IMPROVE ADHERENCE TO UK BLOOD TRANSFUSION GUIDELINES IN A HOSPITAL SETTING

D. Warcel[1,*], R. Moll[1], A. Li[1]
[1]Haematology, Royal Free Hospital , London, United Kingdom

Background: UK guidelines to provide evidence-based support for decisions to transfuse packed red cells were published in 2015 by NICE (National Institute for Health and Care excellence). The guidelines specified Hemoglobin (Hb) targets for transfusion, use of single unit transfusion to avoid over-transfusion, information provision to patients for informed consent, and avoidance of pre-operative transfusion by timely identification of iron deficiency for referral through an anemia pathway. A local baseline audit of NICE compliance at our London tertiary referral hospital showed low overall compliance with these recommendations.
Aims: To determine knowledge amongst the prescriber group of transfusion recommendations for stable patients, to gain insight into current patterns of decision-making for transfusion and to impart knowledge of the key NICE guidance to prescribers.
Methods: An online survey, designed to both evaluate and inform participants, was targeted at doctors of different training grades and specialties during a two week period. The outcomes of this are being used to guide further training.
Results: Of 141 participants who took part in the survey, 31% (43) had been qualified for less than two years and 47% (65) were consultants. Specialties included Surgery, Anesthetics, Internal Medicine, Hemato-Oncology and Intensive Care. 60% (84) had prescribed blood within the last month. Despite only 51% (72) awareness of the NICE guidelines, a significant majority (73%, 103) selected the correct Hb threshold of ≤70g/L for transfusion in patients without acute coronary syndrome (ACS). For patients with ACS, the correct Hb threshold of ≤80g/L was selected by 42% (58), but there was a wide spread of answers. 65% (90) of participants were aware that, in a stable patient Hb is checked after each unit of red cell transfusion, but surprisingly a few (4%, 5) did not check post transfusion Hb at all. Ferritin measurement was inconsistent with only 47% (66) routinely measuring this prior to transfusion, and only 31% (44) aware that a ferritin result over 30 days old should be rechecked. This highlighted potentially inadequate identification of iron deficiency anemia. In addition only 40% (57) were aware of the existence of a hospital anaemia clinic for referral. When reflecting on consent methods, 96% (135) of participants explained the indication to patients, and 90% (127) gave an opportunity to ask questions and ensured the patient was content to proceed. Provision of written information was poor (26%, 37) and only 55% (78) recorded the discussion in patients' notes. Exploring barriers to consent, 24% (32) expressed difficulty in obtaining a patient information leaflet, and issues relating to lack of time and confidence were 16% (22) and 9% (12) respectively.
Summary/Conclusions: Although the majority of participants expressed awareness of the NICE guidance, knowledge was not reflected in subsequent questions. The survey allowed simultaneous assessment of knowledge and provision of key information as a factsheet. Almost all participants felt that completion of the survey had been helpful, and as a tool to reach a highly mobile group, the survey is a constructive and supportive method to facilitate implementation of national guidance by medical staff. We were also able to identify areas that need further development including the clinical referral pathway for the anemia clinic and improving the availability of patient information leaflets on hospital wards. At present we are updating the hospital transfusion policy, which will be disseminated to all hospital staff, and carrying out structured case based discussion sessions with junior doctors to enhance knowledge and confidence.

P406

SCREENING OF TRANSFUSION PRODUCTS FOR PRION DISEASES USING APTAMERS AND TUNABLE RESISTIVE PULSE SENSING

M. Healey[1,*], M. Sivakumaran[2], M. Platt[1]
[1]Chemistry, Loughborough University, Loughborough, [2]Haematology, Peterborough City Hospital, Peterborough, United Kingdom

Background: Prion diseases are a group of fatal transmissible neurological conditions whose disease etiology is characterised by the change in conformation of the normal intrinsic cellular prion protein (PrP^{c}) in to the highly ordered insoluble amyloid state conformer (PrP^{sc}). The significant event fundamental to the progression of these diseases is the self-catalytic, and perpetuating, nature of the conversion of PrP^{c} in the presence of PrP^{sc} aggregates. The emergence of Variant Creutzfeldt-Jakob disease (vCJD), the most predominant prion disease in humans in the United Kingdom during the 1990s, is considered to be an effect of dietary exposure to the bovine spongiform encephalopathy (BSE) agent through contaminated meat products. To date, the widely accepted estimate for the prevalence of vCJD in the UK puts the number of potential carriers at 1 in 2000. Since the disease is known to be infectious and transmissible, the iatrogenic ability of this disease is a significant risk to public health through transfusion products and surgical procedures.
Aims: We aim to develop a reliable and robust assay that can be used as a screening tool to detect the infectious PrP^{sc} protein at low levels in human blood with high selectivity and high sensitivity.
Methods: Here we use a technique based on the Coulter Counter principle that uses tunable elastomeric nanopores termed Tunable Resistive Pulse Sensing (TRPS) to detect the prion protein without an amplification step. The first stage optimises the grafting of an ssDNA aptamer onto nanoparticles. In proof of concept work, the functionalized nanoparticles were then used to detect the cellular prion protein in phosphate buffered saline by monitoring the relative change in velocity through the nanopore, which is then converted to zeta potential. The method was then applied to protein rich samples and serum.
Results: By varying the concentration of aptamer relative to the binding capacity of the nanoparticles, a significant change ($p=0.05$) in zeta distributions was observed. Here mean zeta values were -1.94 mV for 0%; -4.43 mV for 33%; and -7.30 mV for 100%. The assay was further developed by monitoring the functionalized particle's translocation velocity as a function of prion protein concentration. Increasing the concentration of the protein caused shielding of the polyanionic DNA by the positive protein at pH 7.4, therefore the velocity of the protein/particle conjugate decreased. The lowest concentration to have a significant change ($p=0.05$) in velocity distribution was 1 nM, with a 2.5% decrease relative to 0 nM. The higher concentration of 50 nM had a bigger effect of 24% decrease.
Summary/Conclusions: TRPS technology presented here offers the ability to observe the interaction of an aptamer and the prion protein using a particle by particle assay design. Any relative change to the functionalized particle's signal could be observed, demonstrating its capability and suitability to detect biological targets.

Cook[10], M. Kaiser[1,11], M. Drayson[12], R. Owen[13], N. Russell[6], W. Gregory[14], G. Morgan[2], G. Jackson[15]
[1]The Institute of Cancer Research, London, United Kingdom, [2]Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, United States, [3]Clinical Trials Research Unit, Leeds Institute of Clinical Trials Research, Leeds, [4]Heart of England NHS Foundation Trust, Birmingham, [5]Leicester Royal Infirmary, Leicester, [6]Centre for Clinical Haematology, Nottingham University Hospital, Nottingham, [7]University Hospitals of North Midlands, Stoke-on-Trent, [8]Kent and Canterbury NHS Trust, Canterbury, [9]Southampton Hospital, Southampton, [10]Universtiy of Leeds, Leeds, [11]The Royal Marsden Hospital, London, [12]Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, [13]Haematological Malignancy Diagnostic Service (HMDS), St James's University Hospital, [14]Clinical Trial Research Unit, Leeds Institute of Clinical Trials Research, Leeds, [15]Department of Haematology, Newcastle University, Newcastle, United Kingdom

Background: Combining anti-myeloma induction therapies limits the impact of clonal heterogeneity on resistance to therapy, maximising response and associated clinical outcomes. Triplet combinations induce deeper, longer remissions than doublets and those containing an immunomodulatory agent, a proteasome inhibitor (PI) or both are the current standard of care in Europe/US. Potential approaches to further improve outcomes include response-adapted induction, treating suboptimal responders with sequential treatment using an agent with a different mechanism of action, or intensifying induction for all patients by the use of quadruplet combinations upfront.
Aims: The UK NCRI Myeloma XI trial is a large, phase III study comparing, in transplant eligible (TE) patients, the induction quadruplet carfilzomib, cyclophosphamide, lenalidomide and dexamethasone (KCRD) to the sequential strategy of triplet immunomodulatory combinations (with thalidomide or lenalidomide) followed by additional pre-transplant consolidation with PI triplet therapy for those with a suboptimal response.
Methods: In 2013, the TE pathway of the Myeloma XI study was amended to include KCRD given in 28 day cycles (carfilzomib 36mg/m^2 IV d1-2,8-9,15-16 (20mg/m^2 #1d1-2), cyclophosphamide (cyclo) 500mg PO d1,8, lenalidomide (len) 25mg PO d1-21, dexamethasone (dex) 40mg PO d1-4,8-9,15-16). Patients were randomised to this up-front quadruplet or the sequential strategy of CRD (cyclo 500mg PO d1,8, len 25mg PO d1-21 PO daily, dex 40mg PO d1-4, 12-15) or CTD (cyclo 500mg PO d1,8,15 thalidomide 100-200mg PO daily, dex 40mg PO d1-4,12-15) given to max. response. Patients with VGPR/CR proceeded straight to ASCT, those with PR/MR were randomised to sequential CVD (cyclo 500mg d1,8,15, bortezomib 1.3mg/m^2 IV/SC d1,4,8,11, dex 20mg PO d1,2,4,5,8,9,11,12) or nothing and those with SD/PD all received sequential CVD. At day 100 post ASCT there was a maintenance randomisation between lenalidomide and observation. The trial has now closed to recruitment and all patients have completed induction therapy. This analysis compares responses and toxicity of the different regimens.

Table 1.

Response at end of first induction therapy	CTD (n=1021)	CRD (n=1021)	KCRD (n=526)
CR	6.1%	8.4%	18.1%
VGPR	46.8%	52.2%	60.6%
PR	29.7%	25.6%	7.6%
Response at day 100 after ASCT (number completing ASCT to date)	(n=647)	(n=672)	(n=332)
CR	20.9%	23.7%	34.9%
VGPR	56.1%	58.5%	57.5%
PR	16.1%	14.4%	4.8%

Results: 2568 TE patients underwent induction randomisation (CTD 1021, CRD 1021, KCRD 526). Patients were comparable with respect to age (median 59 years), sex and other key laboratory parameters. Patients were mandated to receive a minimum of 4 cycles of initial induction with therapy continued to maximum response. The median number of cycles delivered was CTD: 5, CRD: 5, KCRD: 4. Grade ≥3 haematological toxicities differed between the groups. (Neutropenia CTD: 12%, CRD: 22%, KCRD: 16%; Thrombocytopenia CTD: 3.4%, CRD: 4.5%, KCRD: 8.1%; Anaemia CTD: 6.7%, CRD: 9.6%, KCRD 10%). Grade ≥2 neurological toxicity was greater with the thalidomide-containing regimen (Sensory neuropathy CTD: 9.5%, CRD: 3.4%, KCRD: 2.3%). There was no statistically significant difference in rates of investigator reported, all-grade, thromboembolic events between regimens (CTD: 11.8%, CRD 11.1%, KCRD 14.7%). Response to initial induction and following ASCT is shown in **Table 1** indicating deeper responses with the quadruplet compared to triplets both at the end of first induction regimen (p<0.0001) and, importantly, post-ASCT (p<0.0001). These differences were observed despite the use of randomised pre-transplant consolidation for suboptimal responders to triplet immunomodulatory therapy.
Summary/Conclusions: Induction therapy with KCRD, an outpatient delivered quadruplet regimen, was associated with deeper responses than immunomodulatory triplet therapy (CRD/CTD) and was well tolerated. Deeper responses persisted after ASCT, with an impressive response rate ≥VGPR of 92% with KCRD.

S408

DEEP AND DURABLE RESPONSES WITH WEEKLY IXAZOMIB, LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: LONG-TERM FOLLOW-UP OF PATIENTS WHO DID NOT UNDERGO SCT

S. Kumar[1,*], J. Berdeja[2], R. Niesvizky[3], S. Lonial[4], J. Laubach[5], M. Hamadani[6], A.K. Stewart[7], P. Hari[8], V. Roy[9], R. Vescio[10], J. Kaufman[11], D. Berg[12], E. Liao[12], V. Rajkumar[1], P. Richardson[5]

Background: Triplet combinations that include a proteasome inhibitor (PI) have been proven superior to doublets in newly diagnosed multiple myeloma (NDMM) (San Miguel et al, N Engl J Med 2008, Durie et al, Lancet 2017). The all-oral combination of the novel PI ixazomib plus lenalidomide-dexamethasone (IRd) was evaluated as an induction regimen in NDMM patients, followed by single-agent ixazomib maintenance.
Aims: Here we report updated efficacy and long-term safety data for patients who did not withdraw from the study in order to receive stem cell transplantation (SCT).

Table 1.

Table. Treatment exposure and safety data.

*High-level MedDRA terms; *pooled terms

Methods: In this phase 1/2 study (NCT01217957), patients with NDMM received weekly oral ixazomib (1.68-3.95mg/m^2; days 1, 8, and 15) plus lenalidomide (25mg, days 1-21) and dexamethasone (40mg, days 1, 8, 15, and 22) for up to twelve 28-day induction cycles, followed by maintenance therapy with weekly single-agent ixazomib, at the last tolerated dose given during induction, until disease progression or toxicity.
Results: Of the 65 enrolled patients, 42 continued on study treatment without early withdrawal for SCT; the long-term follow-up of these 42 patients is reported here. Baseline patient characteristics included: median age, 68 years (range 34-86); ISS stage I/II/III in 40%/43%/17%. As of October 18, 2016, with median follow-up of 56 months, the confirmed overall response rate (ORR; ≥ partial response [PR]) was 80%, complete plus very good partial response (CR+VGPR) rate was 63%, and CR rate was 32%. Median time to first response was rapid (0.95 months), while median time to CR was 5.6 months. Median progression-free survival (PFS) in these patients not receiving SCT was 25.3 months. Median overall survival (OS) has not been reached at a median follow-up of 56 months; 3-year OS estimate was 87%. Safety findings are summarized in the Table; 74% of patients had grade ≥3 treatment-related adverse events (AEs), and 26% of the patients had treatment-related serious AEs. Among treatment-related AEs of interest, grade ≥3 rash and peripheral neuropathy were infrequent. There was one treatment-related death due to respiratory syncytial viral pneumonia. After completing 12 cycles of induction therapy with IRd, 25 patients went on to receive maintenance single-agent ixazomib. In these 25 patients, at the end of the induction period ORR was 100%, including 44% VGPR and 32% CR. Responses deepened during maintenance; at data cut-off, the response rates in this maintenance therapy population were ORR 100%, VGPR 32%, and CR 44%. Median PFS for patients who received maintenance therapy was 24 months. The occurrence of the most common treatment-related grade ≥3 AEs (neutropenia, thrombocytopenia, and fatigue) was confined almost exclusively to the induction period. During the maintenance period no patients reported onset of grade ≥3 peripheral neuropathy or rash.
Summary/Conclusions: In patients with NDMM, weekly ixazomib plus Rd, followed by single-agent ixazomib maintenance, was highly active, resulting in deep and durable responses, long PFS, and a high 3-year OS estimate. IRd followed by single-agent ixazomib maintenance also showed an acceptable safety profile, with less toxicity reported during the maintenance (single-agent ixazomib) *vs* induction (IRd) periods, with no evidence of cumulative toxicities.

S409

DEPTH OF RESPONSE AS SURROGATE MARKER FOR PROGRESSION-FREE SURVIVAL AND OVERALL SURVIVAL IN ELDERLY NEWLY DIAGNOSED MYELOMA PATIENTS TREATED WITH VMP AND RD: GEM2010MAS65

[1]Hematology, University Hospital of Salamanca, Salamanca, [2]Hospital 12 de octubre, Madrid, [3]Hematology, Hospital Universitario la Laguna, Santa Cruz de Tenerife, [4]Hematology, Hospital Clínico, Madrid, [5]Hematology, Hospital Clinic, Barcelona, [6]Hematology, HM Hospitales, Madrid, [7]Hematology, Hospital Germans Trials i Pujol, Badalona, [8]Hematology, Hospital Sont Llatzer, Palma de Mallorca, [9]Hematology, Hospital Vall d'Hebron, Barcelona, [10]Hematology, Hospital Virgen del Rocío, Sevilla, [11]Hematology, Hospital San Pedro de Alcántara, Cáceres, [12]Hematology, Hospital Doctor Peset, Valencia, [13]Hematology, Hospital Universitario de Salamanca, Salamanca, [14]Hematology, Clinica Universidad de Navarra, Pamplona, [15]Hematology, Hospital 12 de Octubre, Madrid, [16]Hematology, Clinica Universidad Navarra, Pamplona, Spain

Background: Bortezomib plus melphalan and prednisone (VMP) and lenalidomide plus low-dose dexamethasone (Rd) are two standards of care for elderly untreated MM patients. In order to improve its outcome, we decided to use both VMP and Rd for 18 cycles in a sequential or alternating scheme. After a median f/u of 27 months, both regimens (sequential and alternating) showed similar efficacy with an acceptable toxicity profile.
Aims: To consolidate data, we have updated the outcome with long f/u (51 months), evaluating the role of Complete Response and Minimal Residual Disease (MRD) by multiparametric flow cytometry.
Methods: 242 pts were randomized to receive 9 cycles of VMP followed by 9 cycles of Rd or the same regimens in an alternating approach (one cycle of VMP alternating with one Rd, up to 18 cycles. VMP included the iv administration of weekly bortezomib (except in the first cycle that was given twice weekly) at 1.3mg/m^2 in combination with oral melphalan 9mg/m^2 and prednisone 60mg/m^2 once daily on days 1-4. Rd treatment consisted on len 25mg daily on days 1-21 plus dex 40mg weekly. MRD was evaluated by second generation flow (sensitivity level of 10^{-5}).
Results: 233 pts were evaluable for efficacy. Baseline characteristics of the pts were well balanced in both arms. The median progression-free survival (PFS) was of 30m in the sequential and 32m in the alternating arm (p>0,5). The median overall survival (OS) has been reached in the sequential arm (64m) whilst has not been reached yet in the alternating arm (63% at 5y) (p>0,5). 95 patients (41%) achieved >CR (49 and 46 patients in the sequential and alternating arms, respectively). Pts who achieved >CR had a significantly longer PFS (median of 45m) as compared with pts who didn't (median of 22,3 m) (HR: 0,32; p<0.0001). This translated into a benefit in OS: 73% of pts that achieved >CR remain alive at 5 years whilst the median OS was of 49m for patients that didn't achieve CR (HR: 0,34; p<0,0001). No differences were observed between the sequential and alternating arms. Minimal residual disease MRD was evaluated in 83 out of the 95 pts who achieved >CR. In 46 of them (55%) cells were undetectable with a sensitivity threshold of 10^{-5}, and were considered as MRD-ve patients. These pts displayed a significantly longer PFS (median not reached) as compared to MRD+ve pts (median PFS of 40m) (HR: 0.32; p=0,006) as well as significantly longer OS (HR: 0.26; p=0.012). FISH was available in 174 patients: 32 (18%) were considered high-risk (t(4;14), t(14;16) or del 17p). Outcomes were inferior but not significantly different between the high- and standard-risk groups in terms of PFS (26m vs. 33 months (p=0.11)). The achievement of >CR completely overcome the adverse prognosis of the presence of high-risk cytogenetic abnormalities with a median PFS of 47m and 50m in the high and standard-risk subgroup, respectively (p>0.5). This effect was also evident when MRD negativity was achieved. In terms of OS, the outcome for both high and standard risk subgroup of pts was superimposable during the first 20 months but the curves separated since this point, resulting in a median OS of 40m and 63m (p=0,001), respectively. This effect was maintained for pts that achieved >CR including MRD negativity.
Summary/Conclusions: The present therapeutic approach, based on VMP and Rd for newly diagnosed elderly MM pts represents an optimal therapeutic option for fit elderly patients. Pts who achieved >CR and MRD-flow had significantly longer PFS and OS. The achievement of >CR and MRD negativity is able to overcome the poor prognosis of the presence of high risk cytogenetic abnormalities in terms of PFS but continuous therapy is probably required for high risk patients in order to maintain the benefit in OS.

S410

CARFILZOMIB-LENALIDOMIDE-DEXAMETHASONE *VS* CARFILZOMIB-CYCLOPHOSPHAMIDE-DEXAMETHASONE INDUCTION: PLANNED INTERIM ANALYSIS OF THE RANDOMIZED FORTE TRIAL IN NEWLY DIAGNOSED MULTIPLE MYELOMA

F. Gay[1,*], D. Rota Scalabrini[2], A. Belotti[2], M. Offidani[2], P. Tacchetti[2], M.T. Petrucci[2], C. Pautasso[1], A. D. Palmas[2], A. Siniscalchi[2], M. Grasso[2], A. Spadano[2], N. Palumbo[3], P. Musto[2], M. Boccadoro[1]
[1]Myeloma Unit, Division of Hematology, University of Torino, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, Italy, [3]Myeloma Unit, Division of Hematology, University of Torino - Currently Takeda Pharmaceuticals Co. employee, Torino, Zurigo, Italy, Switzerland

Background: Previous phase I-II studies showed that Carfilzomib-Lenalidomide-Dexamethasone (KRd) and Carfilzomib-Cyclophosphamide-Dexamethasone (KCd) combinations are safe and effective in patients with newly diagnosed multiple myeloma (NDMM) (Jakubowiak Blood 2012, Bringhen Blood 2014).
Aims: The FORTE trial compared KCd *vs* KRd in transplant-eligible patients. Here we report results of the first planned safety interim analysis on induction and mobilization, and preliminary efficacy data.
Methods: NDMM patients younger than 65 years of age were included. Patients were randomized (1:1:1; stratification ISS and age) to: 4 28-day KCd cycles (carfilzomib:20/36mg/m^2 IV d 1, 2, 8, 9, 15, 16; cyclophosphamide 300mg/m^2 d 1, 8, 15; dexamethasone: 20mg d 1, 2, 8, 9, 15, 16) followed by high-dose melphalan and autologous stem cell transplantation (MEL200-ASCT) and consolidation with 4 KCd cycles; or 4 28-day KRd cycles (carfilzomib and dexamethasone as above; lenalidomide:25mg d 1-21) followed by MEL200-ASCT and 4 KRd cycles; or 12 KRd cycles. After the 4th induction cycle, all patients received Cyclophosphamide 2 g/m^2, followed by peripheral blood stem cell collection. For the present interim analysis, we pooled together data of the two KRd groups, because patients in the two groups in fact received the same treatment until mobilization. Data cut-off was October 30, 2016.
Results: A total of 281 patients were evaluated (94 assigned to KCd treatment and 187 to KRd treatment). The most frequent grade 3-4 adverse events (AEs) and serious AEs (SAEs) in both arms were hematological (mainly neutropenia) and infections (mainly pneumonia/fever); increased AST/ALT/GGT (mainly reversible) and dermatological (rash) AEs were more frequent among KRd patients; cardiac AEs were 2% with KRd (including atrial fibrillation [1%] and ischemic heart disease [1%]) *vs* 1% with KCd (atrial fibrillation). Death occurred in 1 patient in the KCd group (infection not treatment-related) *vs* 3 patients in the KRd group (2 cardiac arrest [1 not treatment-related], 1 infection not treatment-related). In the KCd *vs* KRd arms, 99% *vs* 95% (P=0.44) of pts mobilized stem cells (median number of PBSC collected: 9 *vs* 6x10^6CD34/Kg with KCd *vs* KRd). Plerixafor was required in 10% *vs* 24% (P=0.01), respectively. At least a very good partial response (VGPR) was reported in 61% of patients receiving KCd *vs* 74% receiving KRd (P=0.05).

Table 1.

Grade 3-4 AEs/SAEs	KCd	KRd
Hematological	13%	9%
Cardiac	1%	2%
Hypertension	0%	2%
Thromboembolism	0%	1%
Gastrointestinal	0%	3%
AST/ALT/GGT increase	1%*	7%*
Dermatological	0%*	7%*
Infections	6%	9%
Acute Kidney Injury	0%	2%

*p value <0.05

Summary/Conclusions: Safety profile was acceptable; more patients required plerixafor in the KRd arm. Rate of VGPR was higher with KRd. Updated data on a higher number of patients will be presented at the meeting. The trial is registered at Clinicaltrials.gov: NCT02203643

Background: Bortezomib (B) has been reported to be very effective in AL amyloidosis with overall response rates (ORR) varying between 50-80%. However, there are no prospective data from multicenter studies on B treatment in *de novo* patients. We investigated the efficacy and safety of B-Dexamethasone (BD) induction treatment followed by HDM+SCT in *de novo* AL amyloidosis patients.

Aims: The primary aim was to improve the hematological CR rate at 6 months after SCT on intention to treat analysis from 30 to 50%. Secondary aims were OS, PFS, hematologial response rate after BD treatment, organ responses, safety and prognostic factors for survival.

Methods: Patients with biopsy proven AL amyloidosis, aged between 18-70 years, with detectable M-protein and/or level of involved FLC >50mg/L, WHO performance status 0-2, NYHA stage 1-2 and ejection fraction >45% were included. Major exclusion criteria were symptomatic orthostatic hypotension, NT proBNP level >5000 pg/ml, Troponin T> 0.06 ug/l, Bilirubin >2x ULN, eGFR<30 ml/min, CTCAE grade peripheral sensory neuropathy > grade 2 or > grade 1 with pain. Inclusion and exclusion criteria were installed both at entry and before stem cell mobilization (SCM). B was given subcutaneously 1.3mg/m^2 twice a week for 2 weeks in a 21-day cycle, D 20mg orally on each B day and the following day. HDM dosage was 200mg/m^2. Hematological responses were defined according to consensus criteria with the addition of very good partial response (VGPR), defined as the difference between involved and uninvolved FLC<40mg/L. Cardiac, renal and liver response and progression criteria were defined according to consensus criteria with addition of NT proBNP.

Results: Median age was 59 years (range 26-70) and 60% were male. NYHA stage was 1 in 56% and 2 in 42% of patients. Mayo cardiac risk score was I (30%), II (36%), III (34%). Organ involvement was 82% renal, 66% heart, 28% liver, 14% neurological, 8% gastrointestinal and 38% of patients had 3 or more organs involved. Bone marrow plasmacells were >10% in 28% of patients. The median FU for patients alive is 24 (10-55) months. Twelve of 50 (24%) patients could not proceed to SCM. Four patients due to B related toxicity, 3 patients did not fulfill criteria to proceed, 2 patients died (both amyloidosis related) and 3 miscellaneous. Of these 38 patients, 3 went subsequently off protocol because of ineligibility for HDM. Thirty-five out of 50 patients (70%) received HDM + SCT, one patient died of a cardiac arrest after the SCT procedure. The ORR after induction was 80%, ≥VGPR in 54% and CR in 6% of patients. The ORR in the 35 patients at 6 months after SCT was 80%, ≥VGPR in 51% and CR in 43% of patients. On intention to treat analysis the CR rate at 6 months after SCT was 30%. Organ responses at 6 months after SCT were 16/29 renal, 2/8 liver and 13/23 heart. No baseline characterics were identified to be predictive for OS or PFS. BD doses were reduced and delayed after 2 cycles in almost half of patients, mostly because of neurotoxicity, Sensory neuropathy grade 2 or higher was seen in 36% of patients and autonomic neuropathy, mostly dizziness and collapse, in 22%.

Summary/Conclusions: This final analysis demonstrates that the primary aim of improving CR rate at 6 months after SCT from 30 to 50% was not met. This was mainly caused by the high dropout rate before SCT. This may be due to patient selection, but we also demonstrate that BD, given twice weekly sc, despite good efficacy, cannot prevent early amyloidosis related toxicity and can induce grade 2 or higher neurotoxicity.

Background: Nivolumab, a fully human IgG4 monoclonal antibody targeting programmed death-1, is an immune checkpoint inhibitor that augments T-cell activation and antitumor responses. Nivolumab is indicated for pts with relapsed/refractory (RR) classical Hodgkin lymphoma (cHL) following autologous stem cell transplantation (ASCT) and brentuximab vedotin (BV) treatment. The multicohort phase 2 CheckMate 205 trial (NCT02181738) enrolled pts with RR cHL after ASCT. Initial analyses revealed high objective response rates (ORR), encouraging duration of response (DOR) and an acceptable safety profile (Younes A et al, *Lancet Oncol* 2016). Durable responses to therapy are valuable in pts with progressive disease after failure of ASCT due to their limited treatment options.
Aims: To report extended follow-up data for all pts with RR cHL after failure of ASCT in CheckMate 205.
Methods: This single-arm multicenter trial enrolled pts (age ≥18 y) with RR cHL after ASCT into 1 of 3 independent cohorts (Cohort A: BV-naïve; Cohort B: BV only after ASCT; Cohort C: BV before and/or after ASCT). All pts received nivolumab 3mg/kg every 2 wk until disease progression or unacceptable toxicity. Pts in Cohort C with a persistent complete response (CR) for 1 y were to discontinue nivolumab and could resume at relapse. Primary endpoint was ORR per Independent Radiology Review Committee. Secondary endpoints included DOR; progression-free survival (PFS), overall survival (OS), and safety were exploratory endpoints. All pts provided written informed consent.

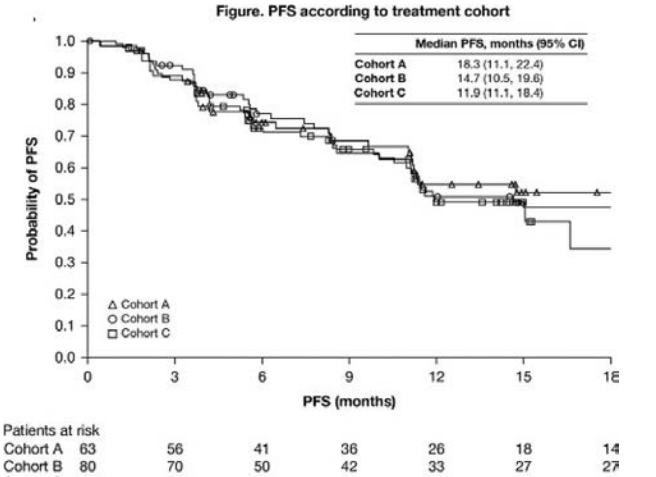

Figure 1.

Results: In total, 243 pts were treated: 63 in Cohort A (BV-naïve), 80 in Cohort B (BV after ASCT), and 100 in Cohort C (BV before [n=33], after [n=58], or before and after [n=9] ASCT). Median (range) age was 34 (18-72) y and 77% of pts had advanced (stage III+) disease at study entry. BV-naïve pts had fewer prior lines of therapy (median of 2 *vs* 4 with prior BV). At Dec 2016 database lock, median (min, max) follow-up was 19 (1, 25), 23 (2, 27) and 16 (1, 20) mo in Cohorts A, B, and C, respectively. Overall, 40% of pts were still on treatment; the most common reason for discontinuation was disease progression (26%). ORR was 65% in Cohort A, 68% in Cohort B, and 73% in Cohort C, with 29%, 13%, and 12% CR, respectively. Median (95% CI) DOR was 20 (13, 20), 16 (8, 20), and 15 (9, 17) mo in Cohorts A, B, and C, respectively. DOR for patients with CR was 20 months for BV-naïve patients (Cohort A) and ≥15 mo for BV-treated patients (Cohorts B and C); DOR for patients with partial response (PR) was 17 and ≥11 months, respectively. PFS by cohort is shown (**Figure 1**). Prolonged median PFS was seen for patients with CR (≥17 mo in each cohort), PR (≥15 mo in each cohort), and stable disease (≥9 mo in each cohort). Median OS was not reached in any cohort. The most common drug-related AEs were fatigue (23%), diarrhea (15%), infusion reactions (IRs; 14%), and rash (12%); grade 3-4 drug-related AEs in ≥3% of pts were lipase increases (5%), alanine aminotransferase increases (3%), and neutropenia (3%). The most common drug-related serious AEs were IRs (2%) and pneumonitis (1%). To facilitate translation to practice, efficacy results by sequencing of prior BV treatment will be presented.
Summary/Conclusion: With extended follow-up, high and durable rates of CR and PR to nivolumab therapy were observed in pts with RR cHL after ASCT, irrespective of BV treatment history.

S. Croce e Carle, Cuneo, Italy

Background: Interim 2-[18F]fluoro-2-deoxy-D-glucose Positron Emission Tomography (FDG-PET) performed after 2 chemotherapy cycles (PET2) is the most powerful predictor of treatment outcome in ABVD-treated, advanced-stage classical Hodgkin Lymphoma (cHL). Preliminary reports showed that adapting treatment to PET2 result could increase the efficacy of standard ABVD.
Aims: To confirm in a prospective setting the favorable prognosis of advanced stage PET2 negative patients treated with ABVD, as well as the safety and efficacy of escalated BEACOPP given to PET2 positive patients.
Methods: We conducted a prospective clinical trial (HD0607 ClinicalTRial.gov identifier 00795613), in which advanced-stage (IIB-IVB) cHL patients were treated with 2 ABVD courses, and PET2 performed afterwards. The latter was blindly and independently reviewed by a panel of nuclear medicine experts, using the Deauville 5-point scale (5-PS). PET2+ patients (5-PS 4-5) were randomized to either BEACOPP escalated (Be) plus BEACOPP baseline (Bb) (4+4 courses) or Be+Bb (4+4) and Rituximab (R). PET2- (5-PS 1 to 3) patients continued ABVD treatment with 4 more cycles and, upon CR achievement, randomized to either consolidation radiotherapy (Rxt) on the sites of initial large nodal mass (LNM: diameter >5cm) or no further treatment (NFT).
Results: Starting from June 2008 till June 2014, 782 cHL patients were consecutively enrolled in 24 Italian and 1 Israeli centers. The median age was 31 years (14-60); 35% had stage IIB, 32% stage III and 32% stage IV. The International Prognostic Score (IPS) was 0-1 in 36.6%, 2-3 in 51%, >3 in 12.5%.

Overall, 150 (19.2%) proved PET2+ (97 score 4, 53 score 5) and 630 (80.5%) PET2-. PET2+ patients were more frequently male (56.7% *vs* 47.1%, p=.03), had higher IPS score (P=.0002) and bulky disease (28.0% *vs* 17.9%; p=.0002). Out of 149 PET2+ patients randomized to Be+Bb (76) or Be+Bb+R (73), 136 were evaluable for response: 93 obtained CR and 43 had a treatment failure. Of the remaining 13 patients, 3 died, 7 withdrew their consent and 3 stopped treatment for toxicity. As per study protocol, 627 out of 630 PET2- patients continued with 4 ABVD cycles and 3 withdrew their consent. Out of 296 with LNM, 148 were randomized to RxT and 148 to NFT. Among 627 patients, 574 (91.5%) achieved CR, 50 (8.0%) had a treatment failure and 3 (0.4%) withdrew their consent. Overall, 30 patients (3.8%) died, due to early death (n=2), resistant disease (n=18; 12 with a positive and 6 with a negative PET2), transplant related toxicity (n=5), infections (n=4) and pulmonary fibrosis (n=1). After a median follow-up of 1303 days (2-2857), the 4-Y PFS and OS for all 782 patients was 83% (95% CI 80%>86%) and 96% (95% CI 94%>97%), respectively. For PET2+ and PET2- patients, the 4-Y PFS was 69% (95% CI 60%>76%) and 87% (95% CI 84%>89%), while the 4-Y OS was 89% (95% CI 82%>93%) and 97% (95% CI 95%>98%) (Figure 1, Panel A and B). No outcome difference was observed for Be+Bb *vs* Be+Bb+R patients, with a 4-Y PFS of 69% (95% CI 57%>79%) and 68% (95% CI 55%>78%), respectively (p=.9731). Consolidation RxT in PET2- patients in CR after 6 ABVD and LNM did not translate in to a significant benefit, with a 4-Y PFS of 96% (95% CI 91%>98%) for RxT and 93% (95% CI 87%>96%) for NFT (p=.2882).

Figure 1. Progression Free Survival and Overall Survival by PET2 -/+

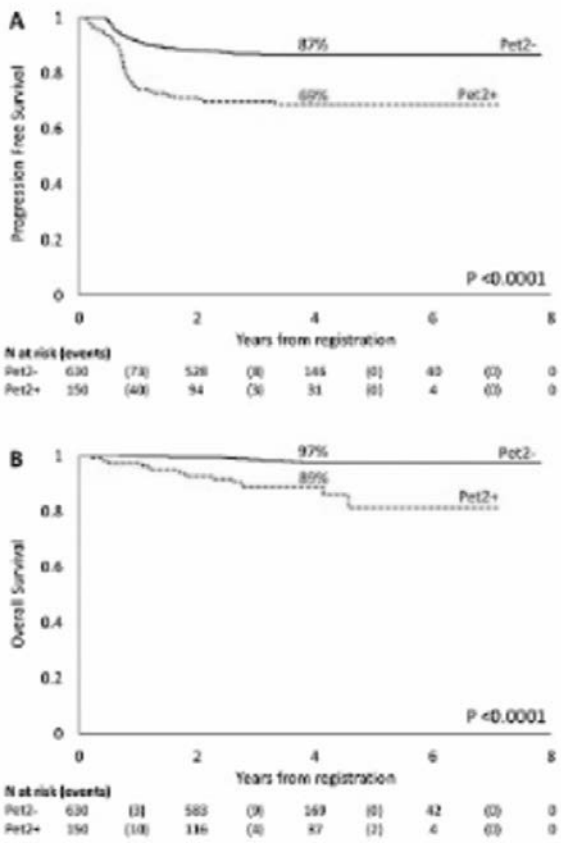

Figure 1.

Summary/Conclusions: These data suggest that 1) an early switch from ABVD to escalated BEACOPP can be safely done in PET2+ advanced-stage cHL; 2) the long-term outcome for the entire patient cohort is superior to standard ABVD; 3) no clinical benefit is associated with post ABVD RxT in PET2- patients presenting with large nodal mass; 4) the addition of Rituximab does not increase the effectiveness of Be+Bb in PET2+ patients.

S414

DISEASE CHARACTERISTICS AND SURVIVAL AFTER 3RD RECURRENCE OF CLASSICAL HODGKIN LYMPHOMA: AN ANALYSIS OF THE GERMAN HODGKIN STUDY GROUP

P.J. Bröckelmann[1,*], H. Müller[1], E. Kücüksarioglan[1], A. Engert[1], B. von Tresckow[1]
[1]Department I of Internal Medicine and German Hodgkin Study Group (GHSG), University Hospital of Cologne, Cologne, Germany

Background: Data on disease presentation, therapeutic options and survival after 3rd or higher relapse of classical Hodgkin lymphoma (cHL) are sparse. Therefore the additional benefit of new agents, which are usually initially investigated after several relapses of cHL, is difficult to estimate.

Aims: The aim of this study was to define and describe a historical control group in European patients from the German Hodgkin Study Group (GHSG) data for comparison of safety and efficacy of novel therapeutic agents.

Methods: Cases with at least three consecutive tumor-related events, either progressive refractory or relapsed disease, were identified in the GHSG database. Detailed information was added from case report forms and physician's letters. Overall survival (OS) was the main and progression free survival (PFS), response to therapy, adverse events, disease and treatment characteristics as secondary endpoints.

Results: Among 12,584 HL patients in the GHSG first-line trials HD7 to HD15 and 449 HL patients in the trials HDR1 and HDR2 a total of 69 cHL patients with ≥3 tumor events were identified. The dates of occurrence of 3rd relapse ranged between 15th of January 1993 and 21st of June 2013. The sample consisted of 51 male (74%) and 18 female (26%) patients. At time of 3rd relapse the age of the patients ranged from 20 to 79 years (mean 39.2 years, standard deviation (SD) 14.0 years) and the majority of patients presented with stage III or IV disease (67%). Time from end of 3rd-line treatment to 3rd relapse was ≤3 months (i.e. GHSG definition of refractory disease) in 15 cases (22%), ≤12 months (early relapse) in 19 cases (28%) and >12 months (late relapse) in 35 cases (51%). All 69 patients were pretreated with chemotherapy, 35 (50.7%) with BEACOPP, 30 (43.5%) with ABVD and no BEACOPP, and 32 (46.6%) with another type of chemotherapy. The number of prior chemotherapies ranged from one to three (median 3). Pretreatment with radiotherapy was observed in 57 (82.6%) patients, with salvage chemotherapy aimed to induce a remission prior to a stem-cell transplantation (SCT) in 58 (84.1%), and with high dose chemotherapy followed by autologous SCT in 50 (72.5%) patients. Four patients (5.8%) had received allogeneic SCT as 3rd-line treatment. None of the patients had received brentuximab vedotin or anti-PD1 antibodies before 3rd relapse. With a median observation time of 63.3 months for OS after 3rd relapse, 45 patients (65.2%) had died and 60 (87.0%) had another PFS event. Twelve months after the 3rd relapse OS was 73.2% (95%>CI 62.6% to 83.8%) and PFS 50.8% (95%>CI 38.9% to 62.8%, Table 1).

Table 1.

	Progression Free Survival (PFS)				Overall Survival (OS)			
		%	95% confidence-interval			%	95% confidence-interval	
	events		Lower limit	Upper limit	events		Lower limit	Upper limit
6 months	16	76.3 %	66.1%	86.4%	7	89.6 %	82.4%	96.9%
12 months	33	50.8 %	38.9%	62.8%	18	73.2 %	62.6%	83.8%
18 months	47	29.5 %	18.5%	40.5%	23	65.6 %	54.2%	77.0%

Summary/Conclusions: Patients with a 3rd relapse or progression of cHL have a dismal, mostly palliative prognosis due to frequent tumor progression. Within one year half of the patients have a PFS event and one fourth die.

S415

A REVISED STAGING SYSTEM FOR WALDENSTRÖM'S MACROGLOBULINEMIA

[1]Greek Myeloma Study Group, Athens, [2]Greek Myeloma Study Group, Thessaloniki, [3]Greek Myeloma Study Group, Piraeus, [4]Greek Myeloma Study Group, Paatras, Greece, [5]Greek Myeloma Study Group, Nicosia, Cyprus, [6]Greek Myeloma Study Group, Larissa, [7]Greek Myeloma Study Group, Alexandroupolis, Greece

Background: Waldenström's macroglobulinemia (WM) is a rare low-grade B-cell lymphoma characterized by the lymphoplasmacytic bone marrow infiltration and the presence of monoclonal IgM immunoglobulin in the serum. WM is an indolent lymphoma that has heterogeneous clinical manifestations and patients with this disease may have a prolonged disease course; however, there are groups of patients with poor outcomes after a relatively short disease course. In order to develop a robust staging system a collaborative effort resulted in the formulation of the International Prognostic Scoring System for WM (IPSS-WM) which was developed in 2009 based on data of patients that were treated primarily without rituximab and mainly with alkylators and nucleoside analogues. IPSSWM is based on five covariates (age, hemoglobin, platelet counts, IgM levels and b2 microglobulin) and stratifies WM patients into 3 broad risk groups. IPSSWM does not take into account non-WM related mortality, which is common and quite different among patients over the age of 75 year and does not include LDH, which is a well identified prognostic factor both in lymphomas and multiple myeloma.

Aims: The aim of the current study was to revise the current IPSSWM by using a large dataset of symptomatic WM patients treated with different types of primary therapy that included rituximab and other new agents.
Methods: The analysis included 492 patients from the prospectively maintained database of the Greek Myeloma Study Group with a median follow up of 10 years. All patients fulfilled criteria for diagnosis and for treatment initiation according to Consensus Recommendations.

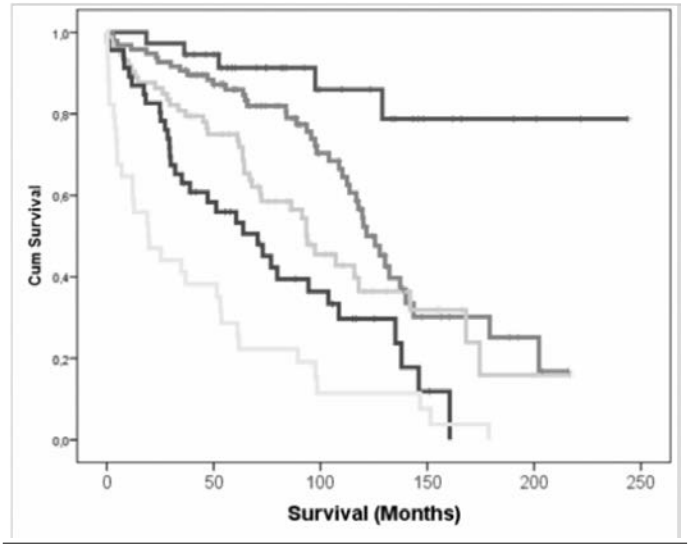

Figure 1.

Results: In univariate analysis factors such as age, beta-2 microglobulin, serum albumin and LDH were all associated with poor outcome. The IPSSWM includes age and b2 microglobulin but not serum albumin, or LDH, while the presence of very high IgM (>7gr/dl) was quite rare and of limited prognostic value. The presence of anemia <11.5gr/dl was common across all subgroups while low platelet counts <100x109/L was found in relatively few patients and had no prognostic significance. Based on ROC analysis for early death (within 3 years), serum albumin <3.5gr/dL and b2microglobulin >4mg/L were the two most important prognostic factors of early WM-related death. Age >65 years was associated with increased risk of death, however, age >75 years conferred additional risk (double hazard of death compared to those 65-75 years and fourfold compared to patients <65 years). Thus, we formulated a score in which high b2 microglobulin, elevated LDH and low serum albumin are scored with 1 point each, age 66-75 years is scored with 1 point but age >75 years is scored with 2. As a result, patients with scores 0, 1, 2, 3 or 4-5 had 3-year WM-related death rate of 3%, 7%, 14%, 19% and 48% (chi-square: 80.7, p<0.001). Regarding overall survival, 10-year survival rate was 85%, 59%, 39%, 28% and 12% (p<0.001) (Figure 1). Because age is a major determinant of disposition we also evaluated this staging system in patients >65 years and retained it prognostic significance. Compared to IPSSWM, this new staging system outperformed ISSWM: c-statistics, a measure of performance of a prognostic tool, was 0.652 for IPSSWM (95%CI 0.627-0.677) *vs* 0.711 (95% CI 0.659-0.763) for the new staging system.
Summary/Conclusions: A revised staging system, based on b2 microglobulin, elevated LDH, low serum albumin and age identifies groups with very different outcomes among patients with symptomatic WM treated with contemporary regimens and may outperform IPSSWM.

[1]Department of Haematology, University Hospital, University of Crete, Heraklion, [2]Department of Haematology, Athens Medical Center-Psychikon Branch, [3]Department of Haematology, University of Athens, Laikon General Hospital, [4]Department of Anatomic Pathology, Evangelismos General Hospital, University of Athens, [5]2nd Department of Internal Medicine, University of Athens, [6]Immunology Laboratory, Laikon General Hospital, [7]1st Department of Propedeutics, University of Athens, Laikon General Hospital, [8]First Department of Internal Medicine, [9]Department of Pathology, University of Athens, Athens, Greece

Background: Rituximab monotherapy has been used successfully in the treatment of SMZL and it can replace splenectomy, at least in 1st line.

Aims: To present our data on the outcome of R monotherapy treated pts after a long term follow-up.
Methods: The diagnosis of SMZL was based on the WHO criteria. Criteria for treatment initiation included: bulky/symptomatic splenomegaly, cytopenias or presence of B-symptoms. All pts received 6 weekly cycles of R as 1st line therapy at a dose of 375mg/m^2 (induction phase). None of the pts had been splenectomised before R treatment. Maintenance with R at a dose of 375mg/m^2 every 2 months for 1-2 years was given according to physician's discretion. Response assessment was based on the SLSG consensus criteria. Survival curves were estimated using the Kaplan Meier method and compared by log-rank test.
Results: 104 pts with SMZL were included. 45% were males with a median age of 66 y (41-91). At diagnosis all pts had bone marrow infiltration with a median % of infiltration of 40 (10-85). Anemia and thrombocytopenia were present in 30% and 19%, respectively. 40% had absolute lymphocytosis. LDH was elevated in 43%. According to the SLSG prognostic system, 39% were classified in group A, 56% in group B and 5% in group C. The median time from diagnosis to treatment initiation was 2 months (0-203). 71 pts received R maintenance. The overall response rate 2 months after the end of induction treatment was 93% (CR, CRu and PR in 42%, 21% and 30%, respectively). Maintenance therapy improved the quality of response in 19 of them, 52 pts maintained their initial response and one relapsed during maintenance phase. The 5- and 10-year PFS, OS and CSS were 70% and 64%, 93% and 88%, 99% and 93%, respectively. Maintenance therapy was associated with better PFS (p=0.008). 22 pts relapsed (6 of them with histologic transformation to DLBCL). 11/22 were retreated with R and 9/11 responded. 8 deaths were recorded: 3 of them disease related. R therapy was well tolerated. Only one pt could not complete treatment due to intolerance.

Table 1.

Table. Baseline characteristics and outcome of 104 SMZL pts treated with R monotherapy

Parameter	# of cases	%
Male sex	47	45
Median age (range)	66 (41-91)	
B-symptoms	7	7
Elevated LDH	44/102	43
Anemia	31/102	30
Thrombocytopenia	19/102	19
Lymphocytosis	40/100	40
SLSG prognostic system		
Group A	39/100	39
B	56/100	56
C	5/100	5
5-year PFS	64%	
10-year PFS	74%	
5-year OS	93%	
10-year OS	88%	
5-year CSS	99%	
10-year CSS	93%	

Summary/Conclusions: The present study, includes a large number of pts with a long follow-up, confirms that R monotherapy is very effective in SMZL with minimal toxicity and is recommended as the treatment of choice for this disease.

Biology of MPN: JAK2 and beyond

S417

YOU DON'T KNOW JAK: A PROGRAMMED RIBOSOMAL FRAMESHIFTING DEFECT POTENTIATES THE TRANSFORMING ACTIVITY OF THE JAK2-V617F MUTATION

S. Sulima[1,*], Y. Khan[2], J. Briggs[2], S. Vereecke[1], J. Jones[2], V. Advani[2], J. Verbeeck[1], K. De Keersmaecker[1], J. Dinman[2]
[1]Department of Oncology, LKI, KU Leuven, Leuven, Belgium, [2]Department of Cell Biology and Molecular Genetics, University of Maryland, College Park, United States

Background: The JAK-STAT pathway is a critical controller of cellular proliferation, differentiation, survival and apoptosis in response to external stimuli. Promiscuous activation of this pathway is an important driver in the pathogenesis of BCR/ABL-negative chronic myeloproliferative neoplasms. The JAK2-V617F allele is the most common and characterized mutation linked to this class of leukemia. The increased activation of JAK-STAT signaling in JAK2-V617F cells can be partially explained by increased JAK2 autophosphorylation. It is unclear however if these effects are sufficient to fully account for the strong activation of the JAK-STAT pathway induced by JAK2-V617F. We recently described programmed -1 ribosomal frameshifting (-1 PRF) as a novel mechanism regulating the expression of ~10% of human genes, including cytokine receptors (Belew AT et al, *Nature*, 2014). In this process, cis-acting mRNA elements (-1 PRF signals, which consist of a slippery site followed by a pseudoknot) direct translating ribosomes to slip by one base in the 5' direction, establishing a new reading frame. This directs ribosomes towards premature termination codons, resulting in destabilization of the -1 PRF signal-containing mRNA via nonsense-mediated mRNA decay (Figure 1). There is thus an inverse relationship between -1 PRF efficiency and mRNA stability.
Aims: To investigate whether the JAK2-V617F mutation, shown here to be located in the pseudoknot of a -1 PRF signal in the JAK2 mRNA, impacts disease progression through ablation of -1 PRF.
Methods: Computationally predicted -1 PRF signals were validated using dual luciferase reporters and proteomic analysis of a -1 PRF fusion protein. -1 PRF as well as mRNA abundance and decay were assayed in HEK293T and HeLa cells. Transformation assays were performed in hEpoR expressing Ba/F3 cells. *in vivo* experiments were performed in BALB/c mice.

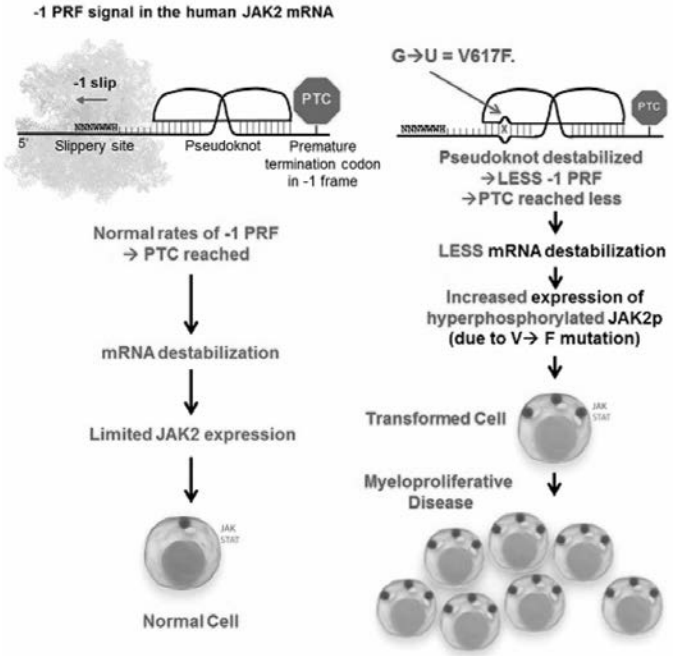

Figure 1.

Results: We demonstrate in human cell lines that the JAK2-V617F mutation structurally disrupts the -1 PRF signal in the JAK2 mRNA, leading to ~2-fold lower rates of -1 PRF and increased abundance of the JAK2 mRNA and protein. The transforming potential of a series of mutants designed to manipulate -1 PRF independent of V617F was assayed in a Ba/F3 cell model. Silent protein coding changes in the pseudoknot of the -1 PRF signal at position V617 (V617m) or the slippery site (SSm), both of which reduced frameshifting, increased JAK2 expression and led to transforming activity, albeit less than V617F. Importantly, the V617F+SSm combination conferred an additive effect on cellular transformation. Ba/F3 cells expressing these JAK2 variants were also introduced into mice. Whereas mice injected with wild type JAK2 remained healthy, both V617m and SSm induced similar leukemia phenotypes as V617F and V617F+SSm, with a ~2-fold longer disease latency of 8-10 weeks. Increased JAK2 mRNA abundance in JAK2-V617F homozygous patients as well as the presence of three additional -1 PRF signals in the JAK2 mRNA further suggest a prominent role for -1 PRF in controlling JAK2 production.
Summary/Conclusions: We demonstrate that the JAK2-V617F mutation diminishes -1 PRF on the JAK2 transcript, stabilizing the mRNA and increasing JAK2 expression, contributing to its transforming activity *in vitro* and disease onset *in vivo*. We suggest that -1 PRF normally provides a layer of control by limiting JAK2 translation. Defective -1 PRF synergizes with the transforming activity of the JAK2-V617F protein by causing its overexpression, explaining why this particular mutation causes such aggressive malignancies. In support of this, the combination of ruxolitinib and an HSP-90 inhibitor, which reduce kinase activity and JAK2 expression respectively, leads to increased therapeutic efficacy in myeloproliferative neoplasms (Bhagwat N et al, *Blood*, 2014).

S418

EFFECTIVENESS OF LSD1 INHIBITION FOR THE TREATMENT OF MPN

J.S. Jutzi[1,*], H. Rienhoff[2], H.L. Pahl[1]
[1]Clinic for Tumorbiology, University Medical Center, Freiburg, Germany, [2]Imago Biosciences, San Francisco, United States

Background: Treatment of MPN with JAK1/2 inhibitors ameliorates symptoms and splenomegaly but does not meaningfully reduce the *JAK2^{V617F}* allele burden. Though curative, stem cell transplantation is associated with extensive morbidity and mortality highlighting the need for novel effective therapies. The histone "lysine-specific demethylase 1A" (LSD1/KDM1A) is being explored as a drug target in AML with several inhibitors already in the clinic. The enzyme is critical for sustaining self-renewal in leukemic initiating cells; inhibiting LSD1 induces monocytic differentiation and reduces engraftment of AML cell *in vivo*. *LSD1* is over-expressed in a number of myeloid diseases including MPN. Preliminary data in a mutant *Mpl* mouse model of MPN showed that a 28-day course of LSD1 inhibition had a beneficial impact on spleen size, cytokines and mutant cell burden. In a mutant *JAK2* mouse model of MPN, we have characterized the disease-modifying activity of the LSD1 inhibitor (IMG-7289), a compound in clinical development for myeloid diseases (NCT02842827).
Aims: We assessed the pharmacodynamic effects of continuous daily treatment with IMG-7289 in a *JAK2^{V617F}* knock-in murine MPN with established disease. Animals were treated for up to 56 days. Outcome measures included complete blood counts (CBC), hematological phenotype, overall survival, spleen size, bone marrow morphology and the *JAK2^{V617F}* allele burden. Moreover, pro-inflammatory cytokine were monitored during the course of treatment as well as chromatin changes by western blotting and ChIPseq.
Methods: *Jak2^{V617F}*-L2 mice were crossed to *MxCRE* mice and displayed a fulminant MPN phenotype without dIdC induction. CBC and BM FACS analysis were conducted as previously described. We designed a qPCR assay to quantitate murine *JAK2^{V617F}* allele burden.
Results: IMG-7289 treatment was exceptionally well tolerated and mice showed drastic decreases in platelet count (208 *vs* 2063*10^3/µl), reticulocytes (800 *vs* 1674*10^3/µl), monocytes and neutrophils 14 days after the start of treatment. HCT and WBC started to decrease after 28 days. While the *JAK2* mutant allele burden increased over time in untreated mice, it decreased in IMG-7289 treated mice and was statistically significantly lower in peripheral blood as well as in spleen. We observed a drastic increase in the pro-inflammatory cytokine CXCL5 in untreated mice during the course of investigation while CXCL5 levels of treated mice decreased to levels of wild-type littermates. Moreover, treated mice showed a highly significantly increased survival over untreated mice, even in a late stage of disease. Lastly, we were able to show that global H3K9me2, which is generally associated with gene expression silencing, was increased in the bone marrow of IMG-7289 treated mice compared to control mice. The remaining pathophysiological data and functional data on epigenetic regulation will be presented.
Summary/Conclusions: The LSD1 inhibitor IMG-7289 normalizes or stabilizes elevated CBCs in a *JAK2^{V617F}* MPN mouse model. It decreases *JAK2* mutant allele burden, pro-inflammatory cytokine levels and confers a clear survival advantage. Our preliminary data show that LSD1 is a potent target with disease-modifying potential in MPN. Clinical studies with IMG-7289 testing this hypothesis have just begun. Owing to its mode of action, altering epigenetics, and the potential reversibility of drug-induced epigenetic remodeling, a long treatment period in MPN patients may be necessary to eliminate disease. Combining IMG-7289 with JAK1/2 inhibitors might accelerate treatment effects.

S419

LOSS OF RAF KINASE INHIBITOR PROTEIN IS INVOLVED IN MYELOMONOCYTIC LINEAGE COMMITMENT AND AGGRAVATES THE DEVELOPMENT OF CHRONIC MYELOMONOCYTIC LEUKEMIA IN A MURINE IN-VIVO MODEL

V. Caraffini[1,*], O. Geiger[1], A. Rosenberger[1], S. Hatzl[1], B. Perfler[1], J.L. Berg[1],

Background: Chronic myelomonocytic leukemia (CMML) is characterized by increased proliferation and myelomonocytic lineage commitment of hematopoietic stem cells (HSCs). Mutations in the RAS-pathway occur frequently in CMML patients and lead to a CMML-like myeloproliferative disorder (CMML-MPD) in mice via causing hypersensitivity to GM-CSF. Loss of RAF kinase inhibitor protein (RKIP), a negative regulator of RAS signaling, is frequent in myelomonocytic and monocytic subtypes of acute myeloid leukemia (AML) and is often associated with RAS mutations. Moreover, RKIP loss has recently been shown to increase the proliferation of AML cell lines.
Aims: In this work, we aimed at investigating the role of RKIP in the development of CMML.
Methods: RKIP expression was measured by immunoblot and quantitative real-time PCR in 23 primary CMML patient samples as well as in CD34+ HSCs, B-lymphocytes, granulocytes and monocytes of four healthy donors. Sequence analysis of CMML samples was done with an Ion Torrent Next Generation Sequencing platform using an amplicon panel covering 39 genes recurrently mutated in myeloid neoplasms. Effects of RKIP on GM-CSF-induced myelomonocytic differentiation were studied in human CD34+ HSCs lentivirally transduced with RKIP shRNA, as well as in a genetic mouse model for RKIP deletion ($RKIP^{-/-}$). Effects of RKIP on CMML development were initially studied in the same $RKIP^{-/-}$ model. Additionally, these mice were crossed with animals exhibiting a somatically inducible mutation in NRAS ($RKIP^{-/-}$Mx1-Cre-$NRAS^{G12D}$) and the severity of CMML-MPD onset was studied at an age of six months.
Results: Loss of RKIP protein expression was observed in 6/23 (26%) CMML patient specimens and was associated with decreased mRNA levels as well (P<0.001). Patients with RKIP loss exhibited an increased percentage of myelomonocytic cells in the peripheral blood (86% *vs* 75%; P=0.0226). One or more mutations affecting the RAS signaling pathway were detected in all specimens with RKIP loss. In addition to the previously demonstrated induction of proliferation, we then aimed to delineate a role of RKIP loss in myeloid lineage commitment. When studying healthy donors, we observed that RKIP expression was high in HSCs and lymphoid cells, but significantly decreased in cells belonging to the myeloid lineage (monocytes, P=0.001 and granulocytes, P<0.001). In functional experiments, knockdown of RKIP increased the GM-CSF-induced myelomonocytic lineage commitment of both, human and murine HSCs (P<0.05 and P=0.0295, respectively). These results could be corroborated in-vivo, as intraperitoneal injection of GM-CSF caused a significant increase of myelomonocytic cells in the intraperitoneal cavity (P=0.006), bone marrow (P=0.007) and peripheral blood (P=0.027) in $RKIP^{-/-}$ mice when compared to their wildtype littermates. In a final step, we evaluated the potential of RKIP loss to cause CMML-MPD in mice. While it proved to be insufficient to cause the disease as a single event in $RKIP^{-/-}$ mice, it aggravated the CMML-MPD phenotype in animals carrying an additional mutation in NRAS. In this case, RKIP deletion caused worsening of leucocytosis (P=0.036) and splenomegaly (P=0.035), which was associated with increased levels of myelomonocytic cells in the bone marrow (P=0.028), peripheral blood (P=0.002) and spleen (P=0.025).
Summary/Conclusions: RKIP loss is a frequent event in CMML and is associated with mutations affecting the RAS signaling cascade. Loss of RKIP is functionally involved in myelomonocytic lineage commitment of HSCs and aggravates CMML-MPD development in mice carrying an additional mutation in NRAS.

JAK2 V617F HAEMATOPOIETIC CLONES WITH DIFFERENT EXPANSION KINETICS ARE DETECTABLE SEVERAL YEARS PRIOR TO MPN DIAGNOSIS

T. Mckerrell[1,2,*], N. Park [2], J. Chi[3], G. Collord[2], T. Moreno[4], H. Ponstingl[2], J. Dias[5], P. Gerasimou[6], K. Melanthiou[7], C. Prokopiou[8], M. Antoniades[7], I. Varela[4], P. Costeas[6], G. Vassiliou[1,2]
[1]Department of Haematology, University of Cambridge, [2]Wellcome Trust Sanger Institute, Cambridge, United Kingdom, [3]The Center for the study of haematological malignancies (CSHM)/Karaiskakio Foundation, Nicosia, Cyprus, [4]Instituto de Biomedicina y Biotecnología de Cantabria (UC-CSIC), Santander, Spain, [5]Cancer Molecular Diagnosis Laboratory, University of Cambridge, Cambridge, United Kingdom, [6]The Center for the study of haematological malignancies (CSHM)/Karaiskakio Foundation, [7]Haematology, Nicosia General Hospital, Nicosia, [8]Haematology, Limassol General Hospital, Limassol, Cyprus

Background: *JAK2* V617F is the most common somatic mutation in the classical myeloproliferative neoplasms (MPNs) and is also frequent amongst healthy individuals with age-related clonal haemopoiesis (ARCH).
Aims: To investigate the pre-clinical clonal evolution of MPNs.
Methods: We identified 12 individuals with *JAK2* V617F mutant MPN from whom blood DNA was available from the time of MPN diagnosis and also from an earlier time point of between 4.5-15.2 years previously (median 10.2 years) when blood was donated for registration to the Cyprus Bone Marrow Donor Registry. We used deep DNA sequencing to interrogate all 24 samples at 15 myeloid mutation hotspots including *JAK2* V617, using an established multiplex PCR/MiSeq sequencing protocol that reliably detects nucleotide substitutions present at a variant allele fraction (VAF) ≥0.008. Additionally, for 12 samples with sufficient DNA available, we performed targeted DNA capture for all exons of 41 genes recurrently mutated in myeloid neoplasms using a custom RNA-bait library followed by sequencing on Illumina HiSeq 2500. Finally, we genotyped archival Registry samples for the rs12343867 single nucleotide polymorphism (SNP) (C/T) linked to the *JAK2* 46/1 haplotype.

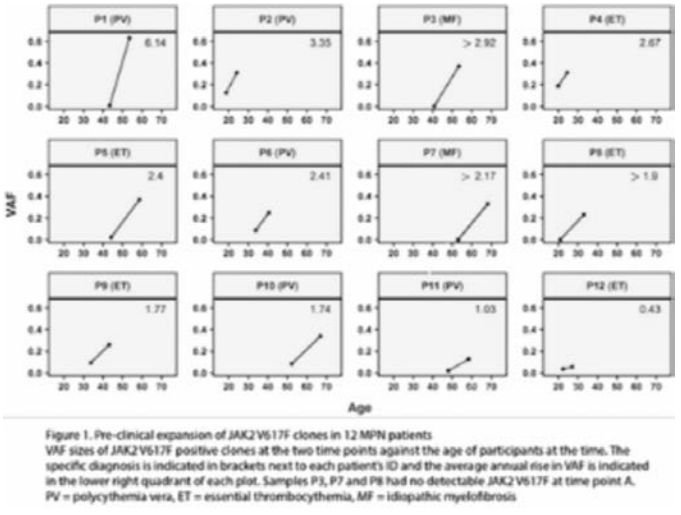

Figure 1. Pre-clinical expansion of JAK2 V617F clones in 12 MPN patients
VAF sizes of JAK2 V617F positive clones at the two time points against the age of participants at the time. The specific diagnosis is indicated in brackets next to each patient's ID and the average annual rise in VAF is indicated in the lower right quadrant of each plot. Samples P3, P7 and P8 had no detectable JAK2 V617F at time point A. PV = polycythemia vera, ET = essential thrombocythemia, MF = idiopathic myelofibrosis

Figure 1.

Results: Amplicon sequencing returned a median coverage of 6641 reads per nucleotide (nt) at the studied hotspots. This confirmed the presence of *JAK2* V617F in all 12 diagnostic and 9 of 12 archival samples. The remaining 3 samples were *JAK2* V617F negative at the sensitivity of our assay (VAF≥0.008). The only other hotspot mutation identified was *SRSF2* P95R in one patient, P3, whom had a diagnosis of myelofibrosis. Pulldown sequencing of all exons of 41 genes from 12 samples with sufficient DNA returned an average coverage of 1978 reads per nt and showed a close correlation in *JAK2* V617F and *SRSF2* P95R VAF quantitations with amplicon sequencing. The *JAK2* V617F VAF at MPN diagnosis differed between patients as expected, however the average rate of clonal growth also varied widely between individuals, ranging from 0.36 to 6.2% per annum (Figure 1). Targeted exon capture from 12 of 24 samples, only identified one co-mutation with a VAF >0.02, the *SRSF2* P95R in patient P3. As this locus was also amplified by amplicon sequencing, we were able to quantify the *SRSF2* P95R VAF in both the diagnostic and the archival DNA sample taken 12.6 years earlier. In the P3 diagnostic sample the VAFs for *JAK2* V617F and *SRSF2* P95R were similar (0.37 and 0.41 respectively) indicating that they co-occurred in most cells of the neoplastic clone. In the archival sample from P3, the *SRSF2* P95R was detectable at a VAF of 0.06, however the *JAK2* V617F was absent/undetectable at the sensitivity of our method (VAF≥0.008) indicating the *SRSF2* P95R was the clone-founding mutation in this neoplasm. The genotyping results for the rs12343867 SNP revealed a tentative association in our small cohort between homozygosity for the risk allele (C) linked to the *JAK2* 46/1 haplotype and the average annual increase in *JAK2* V617F VAF. This will need to be verified in larger studies.
Summary/Conclusions: Our findings reveal that *JAK2* V617F neoplasms develop from clonal haematopoiesis over many years. The rate of clonal expansion of *JAK2* V617F clones in the pre-clinical phase was highly variable and although it was tentatively associated with the 46/1 haplotype, the high variability observed suggests that other factors likely influence clonal progression.

S421

DISRUPTION OF HAEMATOPOIETIC STEM CELL HETEROGENEITY IN A MOUSE MODEL OF MYELOPROLIFERATIVE NEOPLASM

R. Norfo[1,*], C. Di Genua[1], C. Booth[1], A. Giustacchini[1], B. Povinelli[1], N. Gray[2], E. Repapi[2], E. Soilleux[3], L. Jamieson[1], N. Tran[1], A. Green[4], S.E. Jacobsen[15], A. Mead[1]
[1]MRC Molecular Haematology Unit, [2]Computational Biology Research Group, MRC Weatherall Institute of Molecular Medicine, University of Oxford, [3]Nuffield

Division of Clinical Laboratory Sciences, University of Oxford, Oxford, [4]Department of Haematology, Cambridge Institute for Medical Research and Wellcome Trust/MRC Stem Cell Institute, University of Cambridge, Cambridge, United Kingdom, [5]Department of Cell and Molecular Biology and department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden

Background: The hematopoietic stem cell (HSC) compartment in mice encompasses a broad range of heterogeneous cell types including highly lineage-biased HSCs, such as platelet-biased HSCs (PMID:23934107). Myeloproliferative neoplasms (MPNs) are a heterogeneous spectrum of clonal hematopoietic disorders, that includes essential thrombocythemia (ET), a MPN-subtype usually presenting with isolated thrombocytosis. Most ET patients carry a gain-of-function point mutation in JAK2 (JAK2V617F), with several other collaborating hits reported to co-occur with JAK2V617F at lower frequencies, including loss-of-function mutations of the epigenetic regulator EZH2, which are more frequent in advanced MPN.
Aims: Although it is broadly accepted that MPNs are propagated by counterparts of HSCs, the impact of collaborating MPN-associated mutations arising in different HSC subsets remains unclear. We aimed to explore the possibility that platelet-biased HSCs might selectively promote development of an ET phenotype.
Methods: We generated a novel mouse model of MPN that carries a conditional knock-in of heterozygous human JAK2V617F (hJAK2V617F) and the conditional knock-out (KO) of EZH2 together with an inducible Mx1-Cre transgene. To analyse platelet-biased HSC subsets upon onset of the mutation(s), we also crossed in the vwf-eGFP transgene, which is selectively expressed in platelet-biased HSCs.
Results: Compared to wild-type and single mutant mice, EZH2-KO hJAK2V617F mice showed increased platelet counts, including a subset of mice which became acutely unwell with an extreme thrombocytosis. Strikingly, in serial bone marrow (BM) transplantation assays, EZH2-KO fully rescued the previously described hJAK2V617F-associated transplantation defect (PMID:20489053). EZH2-KO hJAK2V617F BM recipients showed long-term serial engraftment that was fully restricted to the platelet and myeloid lineages with a persistent thrombocytosis and absence of lymphoid reconstitution. RNA-sequencing revealed upregulation of several signaling pathways, including Hedgehog, and increased inflammation associated gene expression in EZH2-KO hJAK2V617F HSCs. Unexpectedly in this mouse model of thrombocytosis, phenotypic analysis of the HSC compartment in the BM showed that vwf-eGFP+ve HSCs were selectively lost (fold change[FC]=0.12 p=0.009), while vwf-eGFP–ve HSC numbers remained unaffected (FC=1.06 p=0.88) in Ezh2-KO hJAK2V617F mice. To assess a differential contribution of vwf-eGFP+ve HSCs *vs* vwf-eGFP-ve HSCs in the ability to propagate MPN, we sorted HSCs according to vwf-eGFP expression and transplanted them into recipient mice. Unlike their normal counterparts, which showed lymphoid-biased reconstitution, vwf-eGFP–ve HSCs from Ezh2-KO hJAK2V617F mice primarily gave rise to platelets and myeloid cells. In contrast, vwf-eGFP+ve HSCs from Ezh2-KO hJAK2V617F mice engrafted poorly without recapitulating the disease in recipients.
Summary/Conclusions: In this novel Ezh2-KO hJAK2V617F mouse model, Ezh2 loss collaborates to worsen thrombocytosis and rescue the HSC function defect in hJAK2V617F mice. We also observed a striking disruption of phenotypic and functional HSC heterogeneity in Ezh2-KO hJAK2V617F mice with an unexpected and selective loss of vwf-eGFP+ve HSCs together with subversion of vwf-eGFP–ve HSCs towards platelet-myeloid lineage committment. This previously undescribed disruption of HSC heterogeneity in myeloid malignancy together with the clonal advantage conferred to HSCs by EZH2-KO helps to explain how this collaborating mutation might promote the development of more advanced MPN.

Clinical trials including treatment discontinuation in CML

Background: As safe and effective frontline treatment options for children and adolescents with CML are limited, and no approved therapies exist for patients (pts) resistant/intolerant to imatinib (IM), additional treatment options and alternative formulations are greatly needed for this younger population. Dasatinib (DAS) has proven efficacy in adults with newly diagnosed CML-CP, as well as those resistant/intolerant to IM (Cortes JCO 2016, Shah AJH 2016). Results of a phase 1 study confirmed its dosing and safety in pediatric pts (Zwaan JCO 2013); however, a larger prospective study is necessary to further support the use of DAS in pediatric pts with newly diagnosed or IM-resistant/intolerant CML-CP.
Aims: To determine whether DAS is safe and effective in pediatric pts with CML-CP newly diagnosed or resistant/intolerant to IM enrolled in a phase 2, open-label, nonrandomized prospective clinical trial (CA180-226/NCT00777036).

		92 (80, 97)	97 (79, 100)

[a]Refers to either study treatment discontinuation by pt, or withdrawing consent from further follow-up.
[b]Responses based on ≥20 metaphases.
CI=confidence interval; MMR=major molecular response.

Methods: Pts aged <18 years were recruited into 3 separate cohorts: (1) IM-resistant/intolerant CML-CP treated with DAS tablets 60mg/m^2 QD, (2) IM-resistant/intolerant CML-AP/BP or Ph+ ALL (enrollment closed early due to poor response), and (3) newly diagnosed CML-CP treated with DAS tablets 60mg/m^2 or DAS 72mg/m^2 powder for oral suspension (PFOS) QD for ≥1 year. PFOS dose was increased by 20% to match the exposure of the tablet in order to maintain a desired efficacy based on the findings from a bioequivalence study in adults. Primary objectives were major cytogenetic response (MCyR) for CML-CP resistant/intolerant to IM and complete cytogenetic response (CCyR) for newly diagnosed CML-CP (MCyR >30% and CCyR >55% considered of clinical interest). Study cohorts were not designed to be comparative.
Results: From 145 pts enrolled, 130 were treated; 54% were aged ≥12-<18 years. Within the IM resistant/intolerant group, 25 were resistant, 2 were intolerant, and 2 were undetermined. For pts with CML-CP (n=113), 48% of pts with IM-resistant/intolerant CML-CP and 73% with newly diagnosed CML-CP remained on treatment at the time of this analysis (table 1). Cumulative rate of MCyR >30% was reached as early as 3 months for IM-resistant/intolerant CML-CP, and a cumulative rate of CCyR >55% was reached as early as 6 months for newly diagnosed CML-CP (table). Estimated progression-free survival (PFS) by 48 months was 78% for IM-resistant/intolerant CML-CP and 93% for newly diagnosed CML-CP (table). Reasons for progression were loss of MCyR (n=3 IM-resistant/intolerant; n=4 newly diagnosed), loss of complete hematologic response (n=2 each), and development of CML-BP (n=2 IM-resistant/intolerant; n=1 newly diagnosed). One death was reported in the IM-resistant/intolerant CML-CP cohort 1 year after stopping DAS (gastrointestinal bleeding). Adverse events (AEs) were consistent with reports in DAS-treated adults, except no DAS-related pleural/pericardial effusion, pulmonary edema/hypertension, or pulmonary arterial hypertension were reported here. Hypersensitivity in a newly diagnosed pt was the only DAS-related AE that led to discontinuation.
Summary/Conclusions: Results from the largest prospective and registrational trial of pediatric pts with CML-CP demonstrate that DAS is a safe and effective treatment for pediatric CML-CP. Target responses to first- or second-line that DAS were met as early as 3 and 6 months, respectively, and deep responses were observed. Efficacy and safety of DAS in pediatric pts were similar to those observed in adults; however, unlike in adults, no cases of pleural/pericardial effusion were reported.

S423

INITIAL REDUCTION OF THERAPY BEFORE COMPLETE WITHDRAWAL IMPROVES THE CHANCE OF SUCCESSFUL TREATMENT DISCONTINUATION IN CHRONIC MYELOID LEUKAEMIA (CML): YEAR 2 RESULTS IN THE BRITISH DESTINY STUDY

R. Clark[1,*], F. Polydoros[2], J. Apperley[3], C. Pocock[4], G. Smith[5], J. Byrne[6], S. O'Brien[7], H. de Lavallade[8], L. Read[2], D. Milojkovic[3], L. Foroni[3], M. Copland[9]
[1]Haematology, Royal Liverpool University Hospital, [2]Liverpool Cancer Trials Unit, University of Liverpool, Liverpool, [3]Centre for Haematology, Imperial College at Hammersmith Hospital, London, [4]Haematology, East Kent Hospitals, Canterbury, [5]Haematology, St James University Hospital, Leeds, [6]Haematology, University of Nottingham, Nottingham, [7]Northern Institute for Cancer Research, Newcastle University, Newcastle on Tyne, [8]Haematology, Kings College Hospital, London, [9]Paul O'Gorman Leukaemia Research Centre, University of Glasgow, Glasgow, United Kingdom

Background: In CML, there is considerable current interest in whether some patients can safely discontinue tyrosine kinase inhibitor (TKI) therapy. However, all studies so far have examined patients in stable MR4 at entry, *i.e.* BCR-ABL1/ABL1 ratio ≤0.01%. Patients in stable major molecular response (MMR) but not MR4 (<0.1 but >0.01%) have not been formally studied; neither have the effects of stepwise TKI withdrawal.
Aims: The present British De-Escalation and Stopping Therapy with Imatinib, Nilotinib or sprYcel (DESTINY) study examines treatment de-escalation as a prelude to complete cessation, in patients in not only stable MR4 but also those with MMR but not MR4.
Methods: Trial entry required first chronic phase of CML, TKI treatment for ≥3 years, and either the same TKI (imatinib, dasatinib or nilotinib) since diagnosis or only one switch for intolerance. All PCR tests (minimum of 3) in the 12 months before trial entry must have been ≤0.1% (*i.e.* MMR), each with ≥10,000 ABL1 control transcripts; those with all results ≤0.01% were allocated to the 'stable MR4' group; the remainder to the 'MMR but not MR4' group. Entry criteria were thus virtually identical to the EUROSKI study except that patients with MMR but not MR4 were also separately eligible. TKI treatment was reduced to half the standard dose (imatinib 200mg daily, dasatinib 50mg daily or nilotinib 200mg twice daily) for the first 12 months, then stopped completely. Central PCR monitoring was carried out monthly, expressed according to International Scale. Molecular recurrence was timed as the first of 2 consecutive samples with loss of MMR (>0.1%) and mandated resumption of full TKI dose.
Results: 174 patients (male 98; female 76) were recruited after giving informed consent from 20 UK centres. At entry, 148 patients were receiving imatinib, 16 nilotinib and 10 dasatinib, for a median duration of 6.8 years. We reported at ASH 2016 that after 12 months of half-dose therapy, molecular recurrence was lower in patients with stable MR4 at entry (3 of 125 patients; 2.4%) than in those in MMR but not MR4 (9 of 49 patients; 18.4%) (p<0.001). We now show in the Figure below that during the subsequent 12 months of complete treatment cessation in 117 stable MR4 patients, only 26 further recurrences and 4 withdrawals occurred, giving a recurrence free survival (RFS) of 77% (90% CI: 71-83%) for the overall 24 months for this patient group. The recurrence rate on cessation is higher in the MMR but not MR4 group (20 recurrences and 4 withdrawals among 36 patients during cessation; 39% RFS overall (90% CI: 29-52%); p=<0.001). In both the stable MR4 group and the MMR but not MR4 groups, no difference in RFS was seen between patients in MR4.5 at entry and those not. In multivariable Cox proportional hazards modelling, addition of the baseline entry PCR result did not add to the predictive effect on RFS of the prior 12 month PCR pattern, whereas the duration of TKI treatment was an additional predictive factor (p=0.058; HR 0.93), in line with recent data from EUROSKI. The probability of RFS remains unrelated to age, gender, performance status or prior TKI (imatinib *vs* second generation). No progression to advanced phase was seen; one case lost haematological response.

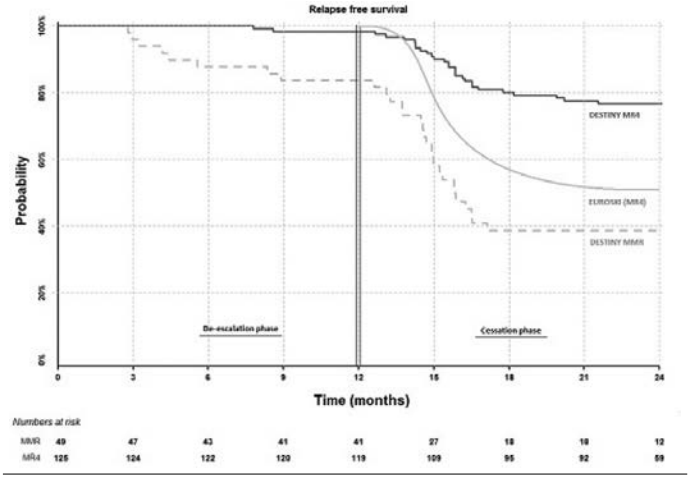

Figure 1.

Summary/Conclusions: The present 24 month RFS of 77% for the overall 24 months in patients in stable MR4 appears better than in any comparable study to date, and implies that the initial 12 months of dose reduction may be responsible, perhaps via improved compliance in the few months prior to stopping or through an as yet undefined mechanism.

Background: The optimum initial treatment of chronic myeloid leukemia (CML) is unknown.
Aims: CML-study IV was designed to confirm the International Randomized Study on Interferon (IFN) and STI571 (IRIS) and to explore whether treatment with imatinib (IM) at 400mg/day could be optimized.
Methods: From July 2002 to March 2012, 1551 newly diagnosed patients in chronic phase (CP) were randomized into a 5-arm study. 1536 patients were evaluable, 400 for IM400mg, 430 for IM + IFN, 420 for IM800mg, 158 for IM + cytarabine and 128 for IM-after-IFN-failure. Recruitment to the latter two arms was stopped after a pilot-phase.
Results: After a median observation time of 9.5 years, 10-year overall survival (OS) of all patients was 82%, 10-year progression free survival 80% and, 10-year relative survival 92%. 10-year OS was 80% with IM400mg, 84% with IM + IFN, 79% with IM800mg, 84% with IM + cytarabine and 79% with IM after IFN (Figure 1). The differences were not significant in spite of faster response with IM800mg. In a multivariate analysis, risk group, comorbidities, major route chromosomal aberrations, smoking and type of treatment center (academic *vs* other) influenced survival, but not gender, transcript type or any form of treatment optimization. Patients reaching the molecular response milestones at 3, 6 and 12 months had a significantly better survival, the faster response of a treatment group (IM800mg) did not translate into a detectable survival advantage.

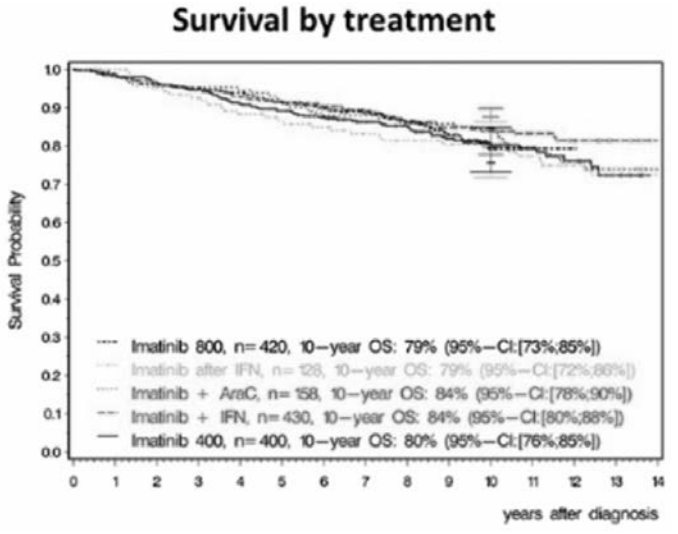

Figure 1.

Summary/Conclusions: Monotherapy with IM400mg provides a close to normal life expectancy. Faster response does not necessarily translate into better survival. Outcome of CML is currently more determined by disease biology and demographics than by treatment optimization.

BOSUTINIB *VS* IMATINIB FOR NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA: INITIAL RESULTS FROM THE BFORE TRIAL

T.H. Brümmendorf[1,*], C. Gambacorti-Passerini[2], M. Deininger[3], M.J. Mauro[4], C. Chuah[5], D.W. Kim[6], L. Reilly[7], A. Jeynes-Ellis[7], E. Leip[8], N. Bardy-Bouxin[9], A. Hochhaus[10], J.E. Cortes on behalf of the BFORE Study Investigators[11]
[1]Universitätsklinikum der RWTH Aachen, Aachen, Germany, [2]University of Milano-Bicocca, Monza, Italy, [3]University of Utah, Salt Lake City, [4]Memorial Sloan Kettering Cancer Center, New York, United States, [5]Singapore General Hospital, Duke-NUS Graduate Medical School, Singapore, Singapore, [6]Seoul St. Mary's Hospital, Seoul, Korea, Republic Of, [7]Avillion LLP, London, United Kingdom, [8]Pfizer Inc, Cambridge, United States, [9]Pfizer Global Research and Development, Paris, France, [10]Klinik für Innere Medizin II, Universitätsklinikum Jena, Jena, Germany, [11]University of Texas MD Anderson Cancer Center, Houston, United States

Background: Bosutinib (BOS) is a potent, dual SRC/ABL tyrosine kinase inhibitor approved for treatment of adults with Philadelphia chromosome-positive (Ph+) chronic myeloid leukemia (CML) resistant or intolerant to prior therapy.
Aims: To assess the efficacy and safety of BOS *versus* imatinib (IM) for first-line treatment of chronic phase (CP) CML in the BFORE trial (NCT02130557).
Methods: In this ongoing, multinational, phase 3, open-label study, 536 patients with newly diagnosed CP CML were randomized 1:1 to BOS 400mg once daily (n=268) or IM 400mg once daily (n=268 [3 not treated]). Informed consent was obtained from all patients. Per protocol, efficacy was assessed in a modified intent-to-treat (mITT) population of 487 Ph+ patients (BOS, n=246; IM, n=241) with e13a2/e14a2 transcripts; Ph– patients and those with unknown Ph status and/or BCR-ABL transcript type were excluded from this population.
Results: After ≥12 months of follow-up, 78.0% of BOS and 73.2% of IM patients remain on treatment with median treatment durations of 14.1 months and 13.8 months, respectively. Major molecular response (MMR) rate at 12 months (primary endpoint) was significantly higher with BOS *versus* IM in the mITT population (47.2% *vs* 36.9%; P=0.02) as well as in the ITT population of all randomized patients (46.6% *vs* 36.2%; P<0.02). In the mITT population, time to MMR was shorter for BOS (hazard ratio=1.34 based on cumulative incidence; P<0.02). Rate of complete cytogenetic response (CCyR) by 12 months was also significantly higher with BOS *versus* IM (77.2% *vs* 66.4%; P<0.008), with time to CCyR shorter for BOS (hazard ratio=1.38; P≤0.001). Rate of BCR-ABL transcripts ≤10% (Intl. Scale) at 3 months was higher with BOS *versus* IM (75.2% *vs* 57.3%; P<0.001); rates of deep molecular response over time were also generally higher with BOS (Table). Results for molecular endpoints were similar in the ITT population. The only baseline characteristic identified as a significant predictor of MMR at 12 months besides treatment arm was Sokal risk group (high *vs* low; P<0.0001 and intermediate *vs* low; P<0.05 [mITT]). On-treatment progression to accelerated or blast phase occurred in 4 patients (1.6%) receiving BOS and 6 patients (2.5%) receiving IM in the mITT population. One BOS-treated and 4 IM-treated patients discontinued treatment due to progression to accelerated or blast phase. Among all treated patients, there were no deaths within 28 days of last dose of BOS and 4 with IM. Safety data for treated patients were consistent with the known safety profiles of BOS and IM. Discontinuation due to drug-related toxicity occurred with 12.7% of BOS patients and 8.7% of IM patients. Grade ≥3 diarrhea (7.8% *vs* 0.8%) and increased alanine (19.0% *vs* 1.5%) and aspartate (9.7% *vs* 1.9%) aminotransferase levels were more common with BOS. Cardiovascular, peripheral vascular, and cerebrovascular events were infrequent in both groups (all grades: 3.0%, 1.5%, and 0% BOS *vs* 0.4%, 1.1%, and 0.4% IM; grade ≥3: 1.5%, 0%, and 0% BOS *vs* 0%, 0%, and 0.4% IM).

Table 1.

Table

Response[a]	BOS (n=246)	IM (n=241)	*P*-value
MMR, n (%)			
3 mo	10 (4.1)	4 (1.7)	0.1156
6 mo	86 (35.0)	44 (18.3)	<0.0001
9 mo	104 (42.3)	71 (29.5)	0.0029
12 mo	116 (47.2)	89 (36.9)	0.0200
MR[4], n (%)			
3 mo	1 (0.4)	0	0.3297
6 mo	24 (9.8)	11 (4.6)	0.0289
9 mo	34 (13.8)	20 (8.3)	0.0593
12 mo	51 (20.7)	29 (12.0)	0.0104
MR[4.5], n (%)			
3 mo	0	0	-
6 mo	5 (2.0)	2 (0.8)	0.2770
9 mo	11 (4.5)	7 (2.9)	0.3758
12 mo	20 (8.1)	8 (3.3)	0.0238

MMR=major molecular response; MR=molecular response.
[a]In the modified ITT population excluding 12 Ph– patients (ie, 0 out of ≥10–99 metaphases at baseline; 6 in each arm), 8 patients with atypical transcripts (3 bosutinib and 5 imatinib), and 31 patients with unknown Ph status (13 bosutinib and 18 imatinib, including 2 imatinib patients also listed as having atypical transcripts).

Summary/Conclusions: Patients on BOS had significantly higher rates of 12-month MMR and CCyR and achieved responses faster than those on IM. Consistent with the known safety profile, higher incidences of gastrointestinal events and transaminase elevations were observed with BOS. Primary results from this study suggest BOS may be an important treatment option for patients with newly diagnosed CP CML.

Background: With imatinib (IM), most patients with chronic myeloid leukemia (CML) achieve deep molecular responses. Six months after stopping tyrosine kinase inhibitor in deep response in the EURO-SKI trial, 61% of the patients were in molecular relapse-free survival (RFS) *i.e.* alive and in major molecular remission (3-log reduction in BCR-ABL1 levels) (Mahon ASH 2016). Between patients with and without BCR-ABL1, the difference in RFS at 6 months was not significant when assessing BCR-ABL1 detectability at the MR4.5 level (at least a 4.5-log reduction in BCR-ABL1) (Pfirrmann ASH 2016).
Aims: For 91 of 448 patients of the EURO-SKI learning sample, the sensitivity to claim undetectable disease at the MR4.5 level was not given. Aim was to investigate whether RFS probabilities would be different when comparing detectable and undetectable disease at the MR4 level.
Methods: Detectability of BCR-ABL1 depends on the number of control gene transcripts. To reduce bias when comparing "MR4 detectable disease" (MR4 but still detectable BCR-ABL1 transcripts; *i.e.* 0.01- 0.0033% IS) and "MR4 undetectable disease" (MR4 without detectable BCR-ABL1; based on 10,000-31,999 ABL1 or 24,000-76,999 GUSB copies), two samples with similar sensitivity of identifying BCR-ABL1 were to be identified using propensity score (PS) matching (Rosenbaum, Rubin 1983). Apart from type (ABL1 or GUSB) and number of control gene transcripts, matching variables were interferon alpha pre-treatment, duration of MR4, and the IM treatment time before observation of MR4. Logistic regression was used to compare RFS at 6 months. Significance level was 0.05.
Results: A total of 448 patients had eligible, complete, and sufficient molecular data prior to and within the first 6 months after stopping IM treatment. All molecular results had sensitivity at the MR4 level with yet detectable disease in 196 patients (44%). With small differences in GUSB copy numbers (used in 96 of 448 cases, U test (detectable *vs* undetectable): P>0.5), prior to PS matching, median numbers of ABL1 transcripts were higher with MR4 detectable disease (78,975 *vs* 68,925 with undetectable disease; P=0.0511, not significant (n.s.)). In 196 patients with detectable disease, RFS at 6 months was 52% (95% confidence interval (CI): 45-59%) and in 252 patients with undetectable disease 63% (CI: 58-69%). Relapse was significantly higher in patients with detectable disease (odds ratio: 1.603 (CI: 1.096-2.343). PS matching resulted in 173 patients per group. Median numbers of ABL1 transcripts changed to 82.142 (detectable) and 75.750 (undetectable disease; n. s.). At 6 months, patients with detectable disease again had 52% (95% confidence interval (CI): 45-59%) RFS probability, and patients with undetectable disease 59% (CI: 52-66%). In the logistic model stratified for the matched pairs, for relapse at 6 months, the odds ratio for MR4 with detectable to undetectable disease was 1.308 (CI: 0.862-1.984, n. s.).
Summary/Conclusions: Using the MR4 threshold, after matching on number of control transcripts and other factors, results suggest little or no impact of detectability of BCR-ABL1 on RFS. Time in deep response seems to be more important. In daily routine, many labs produce reliable outcome at the MR4 but not always at the MR4.5 level. Discontinuation at the MR4 level, irrespective of detectability of BCR-ABL1 residual disease, appears safe, with a good chance of success when performed as in EURO-SKI. With PS matching, bias and differences but also power was reduced. To judge whether molecular response on the MR4 level is sufficient, further data is welcome.

Background: Deregulated expression programs due to genetic alterations, such as gene fusions affecting transcription and/or epigenetic factors is the hallmark of acute myeloid leukemia (AML) and the basis for the associated differentiation block of hematopoietic progenitors. Acute megakaryoblastic leukemia (AMKL) is a subtype of poor prognosis AML affecting primarily young children. Recently, the *ETO2-GLIS2* fusion has been identified in 20-30% of *de novo* AMKL and associated with the worst prognosis in this subtype of AML.
Aims: Our goal was to characterize the mechanisms of cellular transformation induced by ETO2-GLIS2.
Methods: We first defined the consequences of ETO2-GLIS2 expression on hematopoietic progenitors and the contribution of ETO2 and GLIS2 on differentiation and self-renewal by methylcellulose replating assays and phenotype characterization. We then assessed global expression profiling and ETO2-GLIS2 direct binding on DNA by ChIPseq experiments. With immunoprecipitation experiments, we identified some ETO2-GLIS2 complex members. Finally, we tested the effects of a small peptide that could inhibit ETO2-GLIS2 complex stabilization both *in vitro* and *in vivo*.
Results: We showed that the GLIS2 moiety drives the megakaryocytic phenotype whereas both the ETO2 and GLIS2 moieties are required for maintaining self-renewal. Global expression profiling and comparison to patients' signature consistently identified ETO2-GLIS2-mediated deregulation of major transcriptional regulators of hematopoiesis and leukemogenesis. Especially, ETO2-GLIS2 brings on an unbalance in ETS/GATA factors illustrated by an extinction of *GATA1* and an overexpression of the *ERG* oncogene. We identified that ETO2-GLIS2 directly binds DNA via ETO2 complexes and through its GLIS2 moiety. Moreover, the ETO2-GLIS2 fusion localizes at half of H3K27ac-dense enhancers, so called super-enhancers, to control transcription of associated genes, in close association with ERG. Dimerization of ETO2-GLIS2 and interaction with endogenous ETO2 via its NHR2 domains were demonstrated with immunoprecipitation experiments. A NHR2 peptide-interference strategy inhibited the oligomerization, reversed the transcriptional activation at enhancers, promoted megakaryocytic differentiation and abrogated human AMKL cells maintenance *in vivo*. So, the interaction of ETO2-GLIS2 with ETO2 complexes is an essential node for the transcriptional control by the fusion at enhancer elements. Finally, ERG is localized at super-enhancers and is associated with up-regulation of associated genes. ERG knockdown or genetic inactivation downregulates expression of ETO2-GLIS2 targets required for leukemic cells survival. Together, the strong up-regulation of ERG by the fusion and the presence of ERG at super-enhancers suggest a feed forward mechanism to impose gene deregulation.
Summary/Conclusions: In conclusion, we propose that the megakaryocytic differentiation arrest and self-renewal controlled by ETO2-GLIS2 results from imbalanced expression of master transcription factors imposed by aberrant chromatin structures at enhancers that may be disrupted by targeting the NHR2 interface.

NUCLEOSOME BINDING PROTEIN HMGN1 BLOCKS MYELOIDDIFFERENTIATION AND PROMOTES CLONAL DOMINANCE VIA ABERRANT HISTONE ACETYLATION

L. Cabal-Hierro[1,2,*], P. Van Galen[2,3], M. Prado[4], K. Togami[1,2], C. Mowery[1,2], K. Higby[1,2], D. Sykes[3], S. Gygi[4], B. Bernstein[2,3], A. Lane[1,2]

Background: Acute myeloid leukemia (AML) is characterized by rapid growth and block in differentiation of myeloid progenitors. The AML blast is defined by having "open" chromatin. We hypothesized that alterations of chromatin compaction may promote AML. Reversing those changes could represent a novel therapeutic approach.
Aims: Gain of chr21q22 is the most common focal amplification in complex karyotype AML. HMGN1 is a chromatin-regulatory protein on 21q22 known to affect lymphoid development, and our preliminary data suggested that HMGN1 could directly mediate a myeloid differentiation block. Since HMGN1 is known to decompact chromatin and alter histone marks, our goal was to *define and therapeutically target the mechanisms by which HMGN1 overexpression disrupts myeloid differentiation and promotes clonal dominance.*
Methods: We immortalized bone marrow progenitors from wild-type (WT) or OE-HMGN1 mice (transgenic overexpressing HMGN1) with an estrogen receptor-HoxB8 fusion protein. Using exogenous estrogen to control nuclear translocation of HoxB8, we analyzed synchronized myeloid differentiation by flow cytometry, RNAseq, and TMT proteomic analysis. We performed MINT-ChIP-seq (MNase Indexed T7-chromatin IP) to measure the histone marks H3K27ac, H3K27me3, H3K4me3 and total Histone H3. We also measured histone marks in hematopoietic stem and progenitor subpopulations *in vivo*. We performed competitive bone marrow transplantation with CD45.1 WT and CD45.2 OE-HMGN1 donors and measured the relative contribution to hematopoiesis over time.
Results: Synchronized differentiation in WT cells progressed over 6 days from myeloid progenitors to mature neutrophils and monocytes, analyzed by cell surface markers, morphology, and gene and protein expression. OE-HMGN1 cells proliferated faster and remained as undifferentiated myeloblasts (84% Cd11b+Gr1+ in WT *vs* 4% in OE-HMGN1, p=0.002; **Fig A**). Gene set enrichment analysis revealed more similarity to undifferentiated hematopoiesis and leukemia signatures in OE-HMGN1 cells. MINT-ChIP indicated higher global and locus-specific levels of H3K27ac in OE-HMGN1 cells (**Fig B**, upper panel), consistent with an increase in gene transcription, confirmed by RNA-seq. We found a specific increase in HoxA cluster expression in OE-HMGN1 cells, highest at HoxA7 and HoxA9, genes known to be important in AML pathogenesis. In agreement with gene expression, among the most differentially measured histone peaks genome-wide were higher H3K27ac at HoxA gene promoters at all differentiation time points analyzed (**Fig B**, lower panel). Competitive transplantation demonstrated an advantage to OE-HMGN1 stem and progenitor cells. The clonal dominance of OE-HMGN1 over WT cells extended to all populations analyzed (long- and short-term HSCs, multipotent progenitors, CMP, GMP and MEP; **Fig C**) and to mature lineages (myeloid, B and T cells). MINT-ChIP in LK and LKS stem and progenitor cells revealed an increase in H3K27ac peaks at cell cycle and leukemia-related genes in the context of OE-HMGN1. H3K27 acetylation is catalyzed by the CBP/p300 histone acetyltransferase (HAT), suggesting that HAT inhibition could target leukemias with HMGN1 overexpression. Indeed, treatment of myeloid progenitors with the CBP/p300 inhibitor C646 rescued the differentiation block in OE-HMGN1 cells (93% CD11b+Gr1+ in WT *vs* 80% in OE-HMGN1, p=NS).

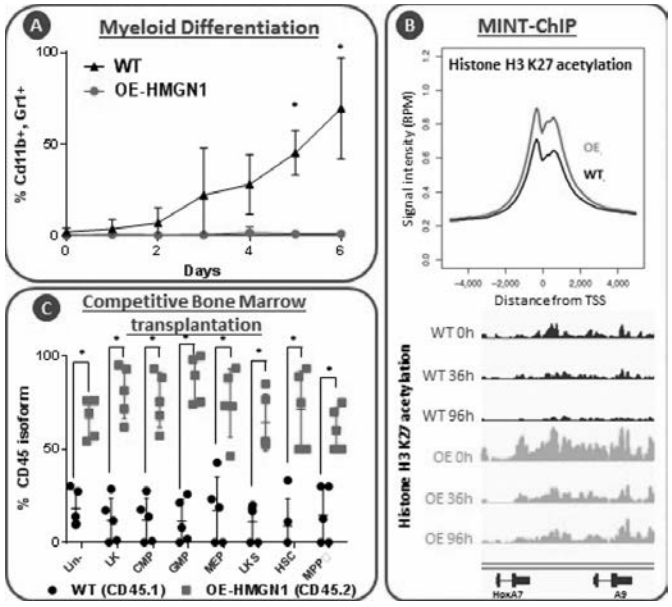

Figure 1.

Summary/Conclusions: Our study suggests that HMGN1 overexpression blocks myeloid differentiation and promotes proliferation in hematopoietic progenitors via increased H3K27 acetylation. Targeting epigenetic changes downstream of HMGN1 or interfering with HMGN1 itself may represent a novel therapeutic strategy in AML.

S429

PIWIL4 ACTS AS A PIRNA BINDING, EPIGENETICALLY ACTIVE AND GROWTH REGULATORY PROTEIN IN HUMAN ACUTE MYELOID LEUKEMIA

S. Bamezai[1,*], M. Mulaw[1], N. Vegi[1], M. Feuring-Buske[1], F. Zhou[2], C. Rohde[2], A. Aravin[3], J. Hoell[4], A. Kloetgen[4], A. Borkhardt[4], C. Plass[5], C. Müller-Tidow[2], V.P. Rawat[1], C. Buske[1]
[1]University of Ulm, Institute for Experimental Cancer Research, Ulm, [2]Department of Medicine IV, Hematology and Oncology, University Hospital of Halle (Saale), Halle (Saale), Germany, [3]Division of Biology and Biological Engineering, California Institute of Technology, Pasadena, United States, [4]Department of Pediatric Oncology, Hematology and Clinical Immunology, Heinrich-Heine-University, Düsseldorf, [5]Division of Epigenomics and Cancer Risk Factors, German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: Piwi proteins are critically important for maintaining the self-renewing stem cell population in lower organisms through epigenetic silencing of transposable elements via DNA methylation and H3K9me3 marks, in close interaction with a novel class of non-coding RNA called piwi interacting RNA (piRNA).
Aims: There are neither precise data on the function of Piwi proteins in human acute myeloid leukemia (AML), nor are there reports on expression of piRNAs in this disease. We employed functional techniques and NGS to understand the role of human PIWI-like protein, PIWIL4 and its associated piRNA in AML.
Methods: We assessed the expression of human PIWIL genes in AML and healthy bone marrow cells using qRT-PCR. Murine stem progenitors were transduced with AML specific oncogenes to evaluate the effect on Piwil4 expression. shRNA mediated knockdown (KD) of PIWIL4 was performed on AML cell lines, AML patient bone marrow (BM) cells and healthy cord blood CD34+ stem progenitors and the impact on growth was determined using *in vitro* and *in vivo* assays. Western blot, ChIP-seq for H3K9me3 and RNA-seq were performed to assess the impact of PIWIL4 KD on the epigenetic landscape and transcriptome of the AML cell line THP-1. IP for PIWIL4 followed by LC-MS was performed to determine the binding partners of PIWIL4. PAR-CLIP and microarray were performed to identify piRNAs that physically bind to PIWIL4 and to test the impact of PIWIL4 KD on piRNA expression.
Results: Among the family of human PIWIL genes, PIWIL4 showed the highest expression level and was ubiquitously expressed in healthy hematopoietic stem/progenitors, mature lymphoid and myeloid cells. Importantly, PIWIL4 was aberrantly higher expressed in more than 89% of the AML patients (n=68; p<0.0001) compared to normal CD34+ BM and total BM cells (n=3). Overexpression of AML specific oncogenes in murine stem progenitors, within 96h post-transduction, induced a 6 to 8 fold increase in Piwil4 expression compared to GFP control (n=3, p<0.0001). Knockdown (KD) of PIWIL4 in AML cell lines significantly impaired proliferation and clonogenic growth *in vitro* (n=3; p<0.001) and delayed onset of leukemia in NSG mice (n=8; p<0.0001). PIWIL4 KD in primary AML patient BM cells lead to 5-fold decrease in clonogenicity (n=3, p<0.001), but had no impact on clonogenicity of healthy stem progenitors *in vitro* (n=4). Western blot and ChIP-seq (n=2, MACS1.4, p<0.01, FDR<0.01) in THP-1 cell line revealed a marked global reduction in repressive H3K9me3 marks upon PIWIL4 KD. Over 500 promoter and 600 gene body associated loci exhibited loss of H3K9me3 marks. RNA-seq analyses revealed over 4000 differentially expressed genes upon PIWIL4 depletion. 30% of the loci that lost H3K9me3 marks at promoters and gene body were differentially expressed in RNA-seq (fold>0.05, adj. p<0.01). These genes belonged to pathways associated with RNA metabolism, transcription and cell death. Moreover, these genes were enriched for binding sites of SETDB1, an H3K9me3 establishing histone methyltransferase (ENRICHR, p<0.01, FDR<0.01). Notably, using IP/LC-MS, PIWIL4 was found to associate with SETDB1 in 293T cells. 560 unique piRNAs were found to physically bind to PIWIL4 and 981 unique piRNAs were differentially expressed upon PIWIL4 depletion in THP-1 cells.
Summary/Conclusions: Thus, collectively, we could show for the first time that PIWIL4 expression is deregulated in human AML and acts as a piRNA binding, epigenetically active growth regulatory protein in human AML.

METTL3 CONTROLS TRANSLATION OF TARGET MRNAS BY N6 METHYLATION OF ADENOSINE RESIDUES IN THEIR CODING SEQUENCE AND CONSTITUTES A NOVEL THERAPEUTIC VULNERABILITY OF ACUTE MYELOID LEUKAEMIA

K. Tzelepis[1,*], I. Barbieri[2], L. Pandolfini[2], J. Shi[3], S.C. Robson[2], V. Migliori[2], A.J. Bannister[2], N. Han[2], E. De Braekeleer[4], H. Ponstingl[5], C.R. Vakoc[6], G.S. Vassiliou[1], T. Kouzarides[2]
[1]Haematological Cancer Genetics, Wellcome Trust Sanger Institute, [2]Gurdon Institute, Cambridge, United Kingdom, [3]Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States, [4]Wellcome Trust Sanger Intitute, [5]Wellcome Trust Sanger Institute, Cambridge, United Kingdom, [6]Cold Spring Harbor Laboratory, Cold Spring Harbor, New York, United States

Background: Acute myeloid leukaemia (AML) patient survival remains below 30% and there have been no major new anti-AML therapies for decades.

Aims: To identify novel therapeutic vulnerabilities of AML.
Methods: A CRISPR-Cas9 drop-out screen was used to identify genetic vulnerabilities of AML. Downstream, we study the function of the RNA methyltransferase METTL3, a novel therapeutic vulnerability of AML. These included in-vitro and in-vivo validation of METTL3 as a therapeutic target using CRISPR/gRNA or shRNA, and investigation of its function using ChIP-seq, RNA-IP-seq, ribosome footprinting (RFP) and bioinformatic analyses.
Results: We performed a genome-wide CRISPR screen on AML cells from *Flt3*$^{ITD/+}$*;Rosa*$^{Cas9/+}$ mice transformed with MLL-AF9 lentivirus and identified >1500 cell-essential genes of which ~250 were AML-specific and included many MLL-AF9 interactors and several putative RNA methyltransferase genes: *METTL1, METTL3, METTL14* and *METTL16* (Fig 1A). Focusing on *METTL3*, we show that its disruption with Cas9/gRNA promoted differentiation of murine and human *MLL-AF9* AML cells and inhibited their growth *in vitro* and *in vivo* (Fig 1B), but did not affect primary murine haematopoietic stem/progenitor cells. To investigate METTL3 function we performed chromatin immunoprecipitation (ChIP) for METTL3 and H3K4me3 and identified 126 METTL3 peaks, localized mainly at promoters with bimodal H3K4me3. METTL3 binding was highest at transcription start sites (TSS) (Fig 1C) and the most enriched transcription factor motif at METTL3 sites was that for the NFY complex. Using available ChIP-seq datasets we found that NFYA, NFYB, H3R2me2s, WDR5 and KLF9 showed strong co-binding with METTL3. Also shRNA knock-down (KD) of WDR5, led to reduced METTL3 binding to target genes SP1 and SP2.
To investigate if/how METTL3 controls expression of target genes we first noted that their mRNA levels were unaffected by METTL3 KD. As METTL3 is an N6-methyladenosine (m6A) methyltranferase, we then performed RNAseq after IP with an m6A-specific antibody (m6A-IP). This identified >4000 METTL3-dependent m6A peaks on poly-A+ RNA. m6A peaks were seen on 72.4% of METTL3-bound gene transcripts and were located in the coding region (CDS) in contrast to STOP codon enrichment in the general transcriptome (Fig 1D). Also, METTL3-bound transcripts were enriched for the [GAG]n motif, which was almost always in the +2 reading frame (Fig1E). As this raised the possibility that m6A may regulate translation of these transcripts, we performed RFP on wild type (WT) and *METTL3* KD MOLM13 cells, to evaluate translational efficiency (TE). Strikingly, upon *METTL3* KD, m6A-marked genes had increased TE, whilst transcripts with METTL3 at their TSS had reduced TE (Fig1F). We then mapped ribosomal pausing sites on mRNAs from METTL3-bound TSSs and found that GAN codons were more occupied (paused) in *METTL3* KD *vs* WT cells (Fig1G). To understand consequences at the protein level, we studied METTL3 targets SP1 and SP2. Remarkably, in contrast to their mRNA levels, SP1 and SP2 proteins were markedly reduced upon *METTL3* KD (Fig1H). SP1 and SP2 targets including c-MYC, were also downregulated upon *METTL3* KD and simultaneous SP1/SP2 gRNA KD markedly reduced proliferation of MLL-AF9/Flt3$^{ITD/+}$ cells.

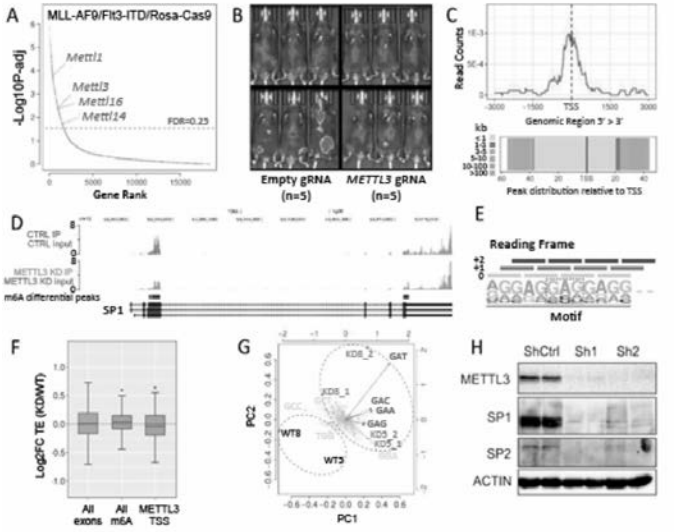

Figure 1: METTL3 controls translational efficiency of mRNAs involved in leukaemogenesis and represents a novel vulnerability in AML
A. Results of genome-wide drop-out screen highlighting METTL genes essential for survival of MLL-AF9-driven AML cells from RosaCas9/+ / Flt3ITD/+ mice. B. Dramatic reduction of luciferase-expressing MOLM13 cell engraftment in immunocompromised (NSG) mice by gRNA against: METTL3. C. Distribution of METTL3 ChIP-seq reads showing that METTL3 binding centres around transcription start sites (TSS) of target genes. D. Visualization of m6A-IP signal on the SP1 gene transcript, showing that the modification is highest in the coding sequence (MOLM13 cells). E. [GAG]n motif enriched in mRNAs from METTL3-bound TSSs, located in the +2 reading frame. F. Reduction in translational efficiency (TE) of *m6A-modified mRNAs* with METTL3 at their TSS, in contrast to other *m6A-modified mRNAs*. G. Principal component analysis of pausing site codon distribution on *mRNAs* from METTL3-bound TSSs identified by ribosome footprinting of METTL3 KD or CTRL MOLM13 cells after doxycycline administration. Note enrichment of "GAN" codons. H. Dramatic reduction in SP1 and SP2 protein levels upon METTL3 KD.

Figure 1.

Summary/Conclusions: Our results show that METTL3 controls translation of specific mRNAs by binding their TSS and introducing m6A at [GAG]n motifs within their CDS, in turn increasing their TE. These mRNAs code for proteins essential for AML cell survival, making METTL3 a novel therapeutic vulnerability of AML.

Acquired and inherited platelet disorders

THE COMBINATION OF ORAL ALL-TRANS RETINOIC ACID AND DANAZOL *VS* DANAZOL AS SECOND-LINE TREATMENT IN ADULT IMMUNE THROMBOCYTOPENIA: A MULTICENTRE, RANDOMIZED, OPEN-LABEL TRIAL

F.-E. Feng[1,2,3], M. Wang[1,2,3], R. Feng[4], J.-M. Zhang[1,2,3], H. Jiang[1,2,3], Q. Jiang[1,2,3], J. Lu[1,2,3], H. Liu[4], J. Peng[5], M. Hou[5], J.-L. Shen[6], J.-W. Wang[7], L.-P. Xu[1,2,3], K.-Y. Liu[1,2,3], X.-J. Huang[1,2,3], X.-H. Zhang[1,2,3,*]
[1]Peking University Institute of Hematology, Peking University People's Hospital, [2]Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, [3]Collaborative Innovation Center of Hematology, Peking University, [4]Department of Hematology, Beijing Hospital, Ministry of Health, Beijing, [5]Department of Hematology, Qilu Hospital, Shandong University, Jinan, [6]Department of Hematology, PLA Navy General Hospital, [7]Department of Hematology, Beijing Tongren Hospital, Beijing, China

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by increased platelet destruction and impaired platelet production. Despite decades of basic and clinical research, the treatment of severe, corticosteroid-resistant or relapsed disease remains a great challenge. Our preliminary study indicated the effectiveness of all-trans retinoid acid (ATRA) for ITP (Wang M, *et al.* ASH 2012, Abstract #3338). This has been coupled with previous discoveries of an immune-modulation effect of ATRA in ITP, including its role to induce changes in Treg cells (Ruan CG 2016), and to correct the imbalance of aberrant macrophage polarization (unpublished data), indicating ATRA as a potential therapeutic regimen. Danazol has been used in the treatment of ITP for more than 30 years. Apart from its haemopoietic stimulatory and immune-modulatory effect, it has recently been shown to reverse abnormal telomere/telomerase function in patients with thrombocytopenia (Townsley DM 2016). The combination of ATRA and danazol may work synergistically based on the mechanism of action targeting both increased platelet destruction and insufficient platelet production.
Aims: To investigate the efficacy and safety of ATRA plus danazol in patients with corticosteroid-resistant and/or relapsed ITP.
Methods: A multicentre prospective study was performed in non-splenectomized corticosteroid resistant/relapsed ITP patients. Participants were at least 18 years of age, had a platelet count of less than 30×10^9/L at enrolment, and did not achieve a sustained response to treatment with full-dose corticosteroids for a minimum duration of 4 weeks or relapsed during steroid-tapering or after its discontinuation. Written informed consents were obtained from all of the participants. The primary endpoint was a sustained response. The secondary endpoints included overall response, time of response, duration of response, incidence of bleeding symptoms and safety.
Results: From 2012 to 2016, 130 consecutive patients were enrolled from 5 different tertiary medical centres in China. Thirty-seven patients were ineligible and excluded, leaving 93 patients randomized to the ATRA+danazol group (n=45) and the danazol group (n=48). At 12 months' follow-up, sustained partial or complete response was achieved in 71.6% of patients in the danazol+ATRA group, significantly higher than 47.2% for danazol monotherapy ($p<0.001$). Additionally, 92.5% and 42.5% of patients receiving ATRA+danazol achieved at least one response (R), while only 58.3% and 11.1% of patients with danazol monotherapy achieved R and CR, respectively. In patients achieving CR or R, the median time to treatment response was 30.5 days with a peak platelet count of 155×10^9/L in the danazol+ATRA group compared with 49 days with a peak PLT of 69×10^9/L in the danazol group. Multivariate analysis revealed that the initial response at day 28 and the median ITP duration were the potential variables associated with a sustained response. There was no treatment-related death due to adverse events. One patient receiving danazol monotherapy died from intracranial haemorrhage 4 weeks after study enrollment.
Summary/Conclusions: Our findings demonstrate that the combination of ATRA and danazol is safe and effective in achieving a rapid and long-lasting response, making it a potential promising therapeutic option for patients with non-splenectomized corticosteroid-resistant/relapsed ITP. This study is registered at www.clinicaltrials.gov as # NCT01667263.

S432

NOVEL PERSPECTIVES IN GENOTYPE-PHENOTYPE CORRELATIONS IN MYH9-RELATED DISEASE: NO LONGER JUST A MATTER OF HEAD OR TAIL

C. Zaninetti[1,*], D. De Rocco[2], A. Pastore[2], V. Bozzi[1], S. Barozzi[1], F. Melazzini[1], A. Savoia[2], P. Noris[1], C.L. Balduini[1], A. Pecci[1]
[1]Department of Internal Medicine, IRCCS Policlinico San Matteo Foundation, and University of Pavia, Pavia, [2]Institute for Maternal and Child Health, IRCCS Burlo Garofolo, and University of Trieste, Trieste, Italy

Background: *MYH9*-related disease (*MYH9*-RD) is an autosomal-dominant disorder caused by mutations in *MYH9*, the gene for non-muscle myosin heavy

chain IIA (NMMHC-IIA), and represents the most frequent inherited thrombocytopenia worldwide. NMMHC-IIA comprises two distinct domains, the N-terminal globular head domain (HD) and the C-terminal tail domain (TD), and causative mutations hit either the HD or the TD. All patients present at birth with macrothrombocytopenia and only some of them develop during life additional manifestations, including nephropathy often leading to end-stage renal disease (ESRD), sensorineural deafness, and/or cataract. Thus, the search for genotype-phenotype correlations in *MYH9*-RD has been an important research topic since the identification of the disorder. In 2008, the analysis of 108 patients allowed to conclude that the mutations affecting the HD were associated with evolution to early-onset ESRD and deafness, whereas the risk of non-hematological manifestations was much lower for patients carrying mutations of the TD. In 2014, raising to 255 the number of patients, we suggested that evolution to juvenile ESRD associated only with the most frequent among HD mutations, *i.e.* substitution of the arginine 702 (R702). Conversely, the other HD mutations, which were almost all localized in a distinct hydrophobic region at the interface between the SH3 subdomain and the motor domain (SH3/MD interface), may be associated with a much less severe evolution.
Aims: To improve prognostic assessment of patients with *MYH9*-RD.
Methods: All the consecutive patients enrolled in the Italian registry for MYH9-RD until June 2016 were included. The association of *MYH9* genotype with phenotype was assessed by a generalized linear regression model (event-free survival analysis).
Results: We enrolled 350 patients belonging to 199 *MYH9*-RD pedigrees. Mutational screening allowed us to identify 6 novel causative mutations in the HD in 6 different pedigrees. Interestingly, all of these variants were localized in the hydrophobic region at the SH3/MD interface. By raising the number of patients with mutations in this region from 14 to 26, and increasing the observation time, we could demonstrate that the mutations in the SH3/MD interface are associated with development of deafness at young-middle age, but low risk of kidney disease and cataract. The other previously identified genotype-phenotype correlations were confirmed. In particular, mutations hitting the R702 in the HD resulted in constant evolution toward juvenile ESRD and severe deafness. Among mutations different from R702 substitutions, the p.D1424H in the TD associated with the highest risk to develop non-congenital manifestations of the disease.
Summary/Conclusions: Mutations in the HD of the NMMHC-IIA are almost all localized in a specific region at the SH3/MD interface, which therefore represents a critical region for *MYH9*-RD pathogenesis. Most importantly, patients with HD mutations are distinguished into two different prognostic groups: subjects with R702 substitutions are expected to early develop a severe syndromic disorder, whereas mutations in the SH3/MD interface are associated with evolution to a milder phenotype, characterized by development of hearing impairment only ("auditory" phenotype). Our study confirmed a genotype-phenotype model for *MYH9*-RD that overcomes the previously reported dualism between HD *vs* TD mutation.

S433

A MONOALLELIC LOSS-OF-FUNCTION MUTATION IN THE THROMBOPOIETIN (THPO) GENE IS RESPONSIBLE FOR A NEW FORM OF INHERITED THROMBOCYTOPENIA (IT)

P. Noris[1,*], C. Marconi[2], D. De Rocco[3], F. Melazzini[1], T. Pippucci[2], G. Loffredo[4], T. Giangregorio[3], E. Cigalini[1], A. Pecci[1], M. Seri[2], A. Savoia[35]
[1]Department of Internal Medicine, IRCCS Policlinico San Matteo Foundation and University of Pavia, Pavia, [2]Department of Medical and Surgical Science, Policlinico Sant'Orsola Malpighi and University of Bologna, Bologna, [3]Institute for Maternal and Child Health, IRCCS Burlo Garofolo, Trieste, [4]Department of Oncology, AO Santobono-Pausilipon, Ospedale Pausilipon, Napoli, [5]Department of Medical Sciences, University of Trieste, Trieste, Italy

Background: The THPO-MPL axis plays a central role in platelet biogenesis: it activates the signaling cascade inducing megakaryocytes (MKs) differentiation from progenitor cells and regulates MKs maturation, proplatelet extension, and nascent platelets release into the bloodstream. Different diseases are known to derive from inherited abnormalities of *MPL* and *THPO*. Gain-of-function mutations in both genes cause congenital thrombocytosis, while loss-of-function mutations in *MPL* result in congenital amegakaryocytic thrombocytopenia: patients affected by this form of inherited thrombocytopenia (IT) present at birth with isolated thrombocytopenia, which always evolves into severe bone marrow aplasia. Similarly, a homozygous loss-of-function variant in the *THPO* gene was found to be responsible for recessive aplastic anemia in a Micronesian family.
Aims: To unravel the molecular basis of ITs and to improve the clinical and laboratory characterization of the new ITs identified.
Methods: Whole exome sequencing (WES) was performed in 86 propositi with an unknown IT. They were part of our case series of 274 consecutive families, 151 of which remained without a definite diagnosis at the end of the diagnostic workup carried out according to the diagnostic algorithm proposed in 2003 by the Italian platelet study group and subsequently updated to include the most recent discovered disorders (Clin Genet 2016;89:141). The investigation was approved by the Institutional Review Board of the IRCCS Policlinico San Matteo Foundation and all patients gave written informed consent.
Results: WES in 86 propositi with unknown IT identified 2 unrelated individuals (family A and B) carrying the heterozygous variant c.91C>T (p. Arg31*), which is expected to result in a mutant protein degradation and THPO haploinsufficiency. In each family the segregation with the disorder was confirmed analyzing one affected relative. Bleeding tendency was absent in all cases. All patients had mild thrombocytopenia; blood film examination did not identify any morphological abnormality of platelets, except for some elements with slightly increased size in patients of family A. *In vitro* platelet aggregation and surface expression of GPIIb/IIIa and GPIb/IX were investigated in the two patients of Family B and gave normal results. The mild severity of thrombocytopenia and the absence of qualitative platelet defects, at least in the two patients of family B, are consistent with the absence of bleeding tendency in affected subjects. THPO serum level was at the lower limit of the normal range in the two subjects of family B, the only available for this assay. This result was in agreement with our hypothesis that *THPO* mutations were expected to result in haploinsufficiency.
Summary/Conclusions: The p.Arg31* mutation in *THPO* causes a new autosomal dominant form of mild, non-syndromic thrombocytopenia. This innocuous disorder is relatively rare (1.3% of families of our case series) but it has to be distinguished from the more severe autosomal dominant ITs with normal platelet size deriving from mutations in *ETV6*, *ANKRD26* and *RUNX1*, since they predispose to the development of hematological malignancies. Because of the similarity of the clinical features and the lack of reliable laboratory markers, we suggest to perform genetic analysis in all subjects with autosomal dominant thrombocytopenia and normal platelet size in order to identify their disorders, define prognosis and organize an appropriate follow-up regimen.

S434

POSITION OF THE GFI1B ZINC FINGER MUTATION DECOUPLES CD34 EXPRESSION FROM ALPHA-GRANULE DEFICIENCY IN GFI1B-RELATED PLATELET DISORDERS

W. Stevenson[1,*], D. Rabbolini[1], M.-C. Morel-Kopp[1], Q. Chen[1], S. Gabrielli[1], C. Ward[1]
[1]Haematology, University of Sydney, Sydney, Australia

Background: GFI1B is a transcription factor that plays an important role in haematopoiesis. Families with a mutation of the fifth DNA-binding zinc-finger domain of GFI1B experience bleeding and have a platelet phenotype characterised by macrothrombocytopenia, increased CD34 expression and alpha-granule deficiency.
Aims: To explore the function of other zinc finger domains of GFI1B we have characterised two unrelated families with a GFI1B variant, C168F, predicted to disrupt the first Zn-finger domain and compared the phenotype with a previously described pedigree with the H294fs mutation that disrupts the fifth Zn-finger domain.
Methods: Clinical platelet phenotypes were determined by light and transmission electron microscopy and functional studies performed by light transmission and whole blood impedance aggregometry. Platelet protein expression was measured by flow cytometry and western blotting. DNA-binding of variants was determined by gel mobility shift assays (EMSA) and changes in gene transcription by luciferase assays. Cellular phenotypes were then studied in patient specific iPSC derived megakaryocytes.
Results: Individuals with GFI1B C168F are thrombocytopenic (mean platelet count =107 $x10^9$/L, n=8) but lack the collagen induced aggregation defects and bleeding symptoms observed in individuals with H294fs (ISTH BAT, P=0.015). Alpha granule content observed by microscopy and quantitated by western blotting of granule related proteins, P-selectin and fibrinogen, were similar between C168F and control platelets and this was significantly greater than that observed for the H294fs mutation (P<0.01). EMSA studies indicate that the C168F variant retains the ability to bind DNA whereas the H294fs mutation altering Zn finger 5 abrogates DNA binding. Despite retaining the ability to bind DNA, the C168F variant de-represses gene transcription at *TUBB1*, *MEIS1* and *CD34* target genes (P<0.01). This de-repression is less marked than that observed with the non-DNA-binding H294fs mutation (P<0.01). The transcriptional de-repression observed at the *CD34* promoter with both Zn finger domain 1 and 5 variants was validated by an increase in platelet surface CD34 measured by flow cytometry and total CD34 protein measured by western blotting (P<0.01). This increased CD34 expression appears specific for *GFI1B* mutation as increased CD34 expression was not observed in platelets derived from individuals with *FLI1*, *RUNX1* or *MYH9* mutation. To validate these clinical observations, iPSCs were generated from the different pedigrees and megakaryocyte differentiation performed *in vitro*. Megakaryocyte CD34 expression was increased in cells derived from individuals with both C168F and H294fs variants but alpha granule deficiency was only observed in cells containing the non-DNA-binding H294fs mutation.
Summary/Conclusions: Mutations altering GFI1B Zn finger 1 cause thrombocytopenia with increased CD34 expression but these platelets retain relatively normal alpha-granule content and these individuals lack clinical bleeding symptomatology. This mutation is mechanistically distinct from the Zn finger 5 mutation that abrogates DNA binding with a subsequent phenotype characterised by alpha-granule deficiency and clinical bleeding.

M. Kopernika w Łodzi, Lodz, [4]Wojewódski Szpital Specjalistyczny im. J. Korczaka, Slupsk, [5]Uniwersyteckie Centrum Kliniczne, Gdansk, [6]Klinika Zaburzeń Hemostazy I Chorób Wewnętrznych, Instytut Hematologii I Transfuzjologii, Warszawa, Poland, [7]Rigel Pharmaceuticals Inc., South San Francisco, CA, United States

Background: ITP is characterized by autoantibody-directed platelet destruction mediated by activated monocyte Fc receptors which signal via spleen tyrosine kinase (syk). A Phase 2 trial of the oral syk inhibitor Fostamatinib (FOSTA) in 16 patients (pts) with refractory ITP provided preliminary efficacy and safety data (Podolanczuk *et al.*, 2009).
Aims: To evaluate the efficacy and safety of FOSTA in adult cITP in 2 parallel, identical, multi-center, randomized, double-blind phase 3 studies (S047 and S048) of 24 weeks duration, followed by an open label study (S049).
Methods: 150 pts with 3 platelet (plt) counts (ct) <30K/μL were enrolled (76 in S047, 74 in S048) with a 2:1 randomization to FOSTA 100mg or placebo bid, and stratification by prior splenectomy and baseline plt ct<or ≥15K/μL. Sixty-one % of pts were female; median age was 54 y (20-88); 93% were Caucasian; 93% had cITP; median disease duration: 8.5 y; median baseline plt ct: 16K/μL. Prior therapies received by pts included 94% steroids, 47% TPO-RAs, 35% splenectomy, and 32% rituximab. Stable response (SR) was defined as a plt ct ≥50K/μL at 4 of 6 biweekly visits over Weeks 14-24; intermediate response (IR) as at least 2 consecutive bi-weekly plt cts ≥50K/μL, both without rescue treatment.
Results: Across both studies, a SR occurred in 18/101 (18%) FOSTA *vs* 1/49 (2%) placebo pts (p=0.007); 11 additional FOSTA and no placebo patients achieved an IR, making the overall response rate 29% (29/101) for FOSTA *vs* 2% (1/49) for placebo (p<0.0001). The median plt cts were 95K, 49K, 20.5K and 17.5K/μL in SR, IR, non-responders (NR) and placebo pts, respectively. In SR and IR, median time to first plt ct ≥50K/μL was 2 weeks. Age (< or ≥65 y), gender, baseline plt ct <15K/μL, prior TPO-RA or splenectomy did not substantially affect response. In S049, 9/41 (22%) pts newly treated with FOSTA have a SR, consistent with S047 and S048. Fifty-four of 101 (54%) FOSTA pts and 14/49 (29%) placebo pts had a plt increase ≥20K/μL (p=0.005). Three of 18 (17%) SR and 1/11 (9%) IR to FOSTA compared to 26/72 (36%) NR and 22/49 (45%) of the placebo group received ≥1 rescue medication, respectively. In S047-S048, serious bleeding occurred in 5.6% of the NR and 10.2% of placebo pts, but not in the 29 responders. The number of pts with ≥1 adverse event (AE) was similar in FOSTA *vs* placebo (83% *vs* 75%). The majority AEs on FOSTA were mild or moderate; all resolved over time. Most common AEs were: diarrhea (29% *vs* 15%), nausea (19 *vs* 8%), hypertension (20% *vs* 8%), ALT/AST increase (10% *vs* 0%). Serious AEs were reported in 13% FOSTA *vs* 21% placebo pts.
Summary/Conclusions: Fostamatinib substantially improves plt cts in certain pts with heavily pre-treated, severe cITP of long disease duration. AEs are mostly mild or moderate in severity. Given its unique mechanism of action based on inhibition of syk, FOSTA could, if approved, be an important alternative as single agent and be a useful component of combination therapy for pts with difficult cITP.

Background: Children with Down syndrome (DS) are prone to development of high risk B cell precursor (BCP) acute lymphoblastic leukemias (DS-ALL) that differ genetically from most sporadic pediatric ALLs. Chromosomal rearrangements causing increased expression of CRLF2, the receptor for thymic stromal lymphopoietin (TSLP), characterize about half of DS-ALLs.
Aims: Understanding the pathogenesis of relapse of DS-ALL relating to their CRLF2 status.
Methods: Integrative genomic analysis of matched diagnosis remission and relapse DS-ALLs, pharmacological inhibition and genetic CRISPR mediated silencing.
Results: Genomic analysis of 25 matched diagnosis remission and relapse DS-ALLs reveled lesions affecting known driver genes in the samples. In 80% of the patients we detected activating mutations in genes whose protein products are involved in signaling, including receptors (CRLF2, IL7R, FLT3), or downstream effector enzymes (JAK1/2, KRAS and NRAS). In contrast to a previous report, we observed that lesions in CRLF2 are early events during DS-ALL evolution, as is evident by its high allelic frequency, and are maintained at relapse. The genetic make-up differed significantly between these two major subtypes of DS-ALLs. CRLF2neg DSALLs were characterized by enhanced RAS signaling coupled by mutations in chromatin remodeling genes, in particular CREBBP. In contrast CRLF2pos DS-ALLs were characterized by high dynamics of proliferative signaling. At diagnosis CRLF2 rearrangements were almost always combined with secondary activating signaling events in JAK-STAT pathway suggesting that signaling is driving the development of these leukemias. However JAK2 mutations were often lost at relapse and replaced by clones with mutated RAS. Thus the presence of JAK2 activating mutations at the time of diagnosis are associated with sensitivity to upfront chemotherapy. Surprisingly we discovered loss-of-function mutations or deletions of USP9X, a deubiquitinase previously described as an oncogene that positively regulates JAK2 signaling, in 25% of CRLF2pos ALLs, in both our study and published data,. We therefore tested the counterintuitive hypothesis that loss of a positive regulator of JAK2 enhances the fitness of JAK-STAT driven JAK2 mutated leukemic cells. Both pharmacological inhibition and genetic CRISPR mediated silencing of USP9X reduced STAT5 phosphorylation and enhanced the survival of CRLF2-JAK2R683Gs transduced ALL cells. To test directly the effect of JAK inhibition, we treated CRLF2/JAK2R683G transduced cells with increasing doses of ruxolitinib, a JAK inhibitor currently in clinical trials for CRLF2-JAK-STAT ALLs. Strikingly while high doses (>2μM) were cytotoxic, low doses (0.25μM) enhanced the survival of CRLF2-JAK2R683Gs expressing ALL cells.
Summary/Conclusions: These observations suggest that genetic or pharmacological restraining of JAK-STAT signaling may be beneficial to leukemic B cell precursors by enhancing the fitness of JAK-STAT "driven" ALL. This and the reduction of JAK-mutated clones at relapse suggest that the therapeutic effect of JAK2 specific inhibitors may be limited. Rather, combined signaling inhibitors or direct targeting of the TSLP receptor may be a useful therapeutic strategy for DS-ALL.

TNF RECEPTOR 2 IS REQUIRED FOR RIP1-DEPENDENT CELL DEATH IN LEUKEMIA

J. Aguadé-Gorgorió[1,*], S. McComb[1,2], M.P. Dobay[3], C. Mezzatesta[1], G. Cario[4], C. Eckert[5], A. von Stackelberg[5], M. Stanulla[6], M. Schrappe[4], J.-P. Bourquin[1], B. Bornhauser[1]

Background: Persistence of residual leukemia cells, due to deficiencies in apoptotic programs, is a major driver of relapse. Activation of alternative non-apoptotic cell death pathways such as necroptosis represents an attractive strategy to eliminate residual leukemia cells and prevent relapse. We have previously shown that SMAC-mimetics (SM) potently induce cell death by simultaneous RIP1-dependent apoptosis and necroptosis in a subset of refractory acute lymphoblastic leukemia (B-ALL) patient-derived samples. The molecular signals that drive sensitivity to RIP1-dependent cell death remained elusive so far.
Aims: The aim of this project was to understand the mechanisms that determine the specific vulnerability to necroptosis in ALL.
Methods: To identify molecular determinants of sensitivity to SM, we correlated the gene expression profiles of 17 primary samples with high and low sensitivity to SM with the IC50 in response to two SM compounds, birinapant and LCL161. We confirmed the top scoring genes including TNF receptor 1 (TNFR1) and TNFR2 by quantitative RT-PCR in patient-derived xenografts. We further validated our results by quantifying the expression of the candidate genes in an independent cohort of relapsed primary B-ALL and by screening samples with different expression levels of TNFR1 and 2 for their response to SM *in vitro*.
To assess the mechanistic role of TNFR1 and 2 in the response to SM, we generated patient-derived TNFR1 and TNFR2 knockout cells using the CRISPR/Cas9 gene editing technology, and evaluated their response to SM *in vitro* and *in vivo* using a CRISPR selection model. Additionally, we overexpressed TNFR2 and evaluated the cell death phenotype. To determine the mechanism of TNFR2-mediated sensitization to SM, we investigated the formation of the pro-death RIP1-TNFR1 complex in wild type *versus* TNFR2ko and in SM sensitive and resistant ALL by immunoprecipitation in primary ALL samples.
Results: Comparative gene expression profiling indicated a correlation of the expression of TNFR2 with sensitivity to SM in primary ALL. Using an independent cohort of relapsed ALL samples, we found that high TNFR2 expression predicted sensitivity to SM in an *ex vivo* model of the bone marrow. Deletion of either TNFR1 or TNFR2 using CRISPR/Cas9 in patient-derived ALL conferred resistance to treatment with SM *in vivo* in the xenograft model, indicating that TNFR1 and 2 are both functionally required for cell death. In agreement with an important role for TNFR2 in the response to SM, the overexpression of TNFR2 leads to increased sensitivity to the TNFR1/RIP1 death axis. On the mechanistic level, recruitment of RIP1 to TNFR1 is a key event in the activation of cell death, which is abolished in TNFR2-deficient leukemia and does not occur in SM resistant cases.

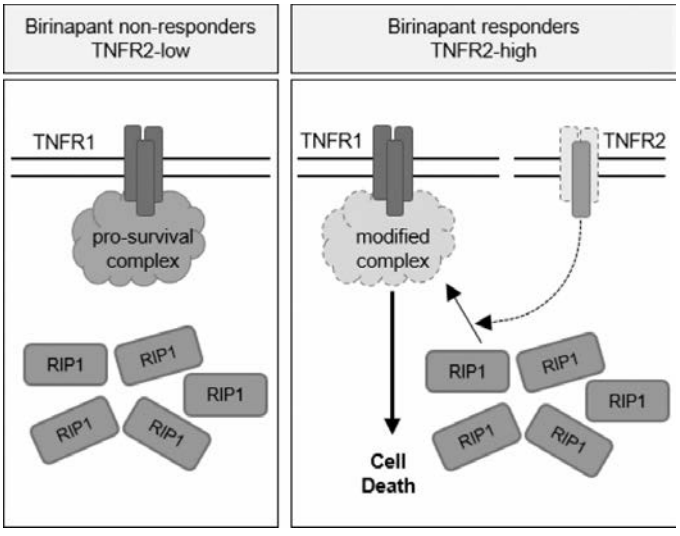

Figure 1.

Summary/Conclusions: Taken together, our data reveal a novel function of TNFR2 in cell death signaling, as TNFR2 predicts sensitivity to SMAC mimetics and plays a key role in activating the TNFR1/RIP1 cell death pathway, which underlies the switch from RIP1-controlled cell survival to cell death and characterizes a distinct vulnerability in ALL.

THERAPEUTIC TARGETING OF ONCOGENIC MYB ACTIVITY IN T-ALL

T. Pieters[1,*], S. T'Sas[1], J. Morscio[1], F. Matthijssens[1], K. Lemeire[2], T. Hochepied[2], B. Lintermans[1], L. Reunes[1], J. Haigh[3], G. Berx[2], S. Goossens[1], P. Van Vlierberghe[1]

Background: T-lineage acute lymphoblastic leukemia (T-ALL) is an aggressive hematologic malignancy that accounts for 10%–15% of pediatric and 25% of adult ALL cases. The prognosis of T-ALL has gradually improved, however, the outcome of T-ALL patients with primary resistant or relapsed leukemia remains poor. Thus, further advances in the treatment of T-ALL require the development of effective and highly specific molecularly targeted antileukemic drugs. The proto-oncogene *MYB* (encodes c-MYB) is aberrantly activated in a subset of T-ALL patients through T-cell receptor driven translocations or genomic duplications of the MYB locus itself. Recently, a new genetic mechanism for the generation of oncogenic super-enhancers in malignant T cells was identified, and suggests a general role for MYB in the regulation of T-cell specific super-enhancer activity.
Aims: We want to identify the role of enhanced MYB activity in super-enhancer driven oncogenic transcription in the context of malignant T-cell development and investigate the *in vivo* role of *cMyb* in the initiation and maintenance of T-ALL.
Methods: To evaluate if *cMyb* could act as a bona fide oncogene in the pathogenesis of T-ALL, we developed a conditional R26-driven cMyb overexpression mouse model. For this, we used a targeting vector that contained a floxed stop cassette followed by the *cMyb* gene and a EGFP/luciferase reporter, which was subsequently targeted in mESCs using recombinase-mediated cassette exchange (RMCE).
Results: Here, we report a novel conditional Myb knockin mouse model (R26-Myb). To study the *in vivo* oncogenic capacity of Myb, we initially crossed this conditional Myb knockin model with VaviCre mice, in order to obtain hematopoeitic specific expression of Myb and the EGFP/luciferase from the ROSA26-promoter. Notably, Vav-iCre$^{tg/+}$ R26-Myb$^{tg/tg}$ mice developed T-cell lymphomas with a median latency of 77 weeks, suggesting that Myb can act as a *bona fide* oncogene in malignant T-cell transformation (Figure 1A). Next, we crossed our Myb transgenic model with Pten conditional knockout mice, to allow comparative analysis of tumors with and without T-cell specific Myb expression. Genetic inactivation of *Pten* is frequently observed in human T-ALL, and T-cell specific deletion of *Pten* (using Lck-Cre) results in T-cell leukemia/lymphoma development with an average of 17 weeks. Using this strategy, we obtained mice that overexpress R26-driven cMyb and lack Pten in developing T-cells and found that cMyb expression synergizes with Pten deletion, resulting in fully penetrant and accelerated T-ALL formation (median survival of 84 days instead of 118; p =0.0003; Figure 1B). Finally, we used this novel murine T-ALL model to identify new therapeutic strategies for MYB dependent T-ALL. Importantly, the tumor cells from the cMyb knockin mice are luciferase-positive and are therefore suitable for *in vivo* drug testing using bioluminescence. Using this model, we evaluated the *in vivo* anti-leukemic efficacy of a variety of small molecules and identified new drugs that impede Myb protein stability or Myb-mediated transactivation in Myb driven tumorigenesis.

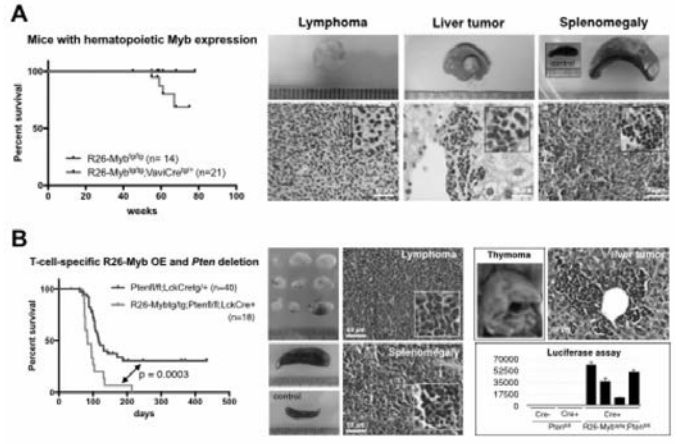

Figure 1.

Summary/Conclusions: We developed a novel Myb-driven T-ALL mouse model and could demonstrate a pathogenic role for *cMYB* in T-cell leukemia. In addition, the Myb-driven preclinical mouse model will open new avenues for therapeutic intervention in T-ALL.

S439

THE T-CELL LEUKEMIA ASSOCIATED RIBOSOMAL RPL10 R98S MUTATION ENHANCES JAK-STAT SIGNALING

T. Girardi[1], S.O. Sulima[1], S. Vereecke[1,*], Y. Khan[2], L. Fancello[1], Z. Flickinger[2], C. Schwab[3], J. Op de Beeck[1], J. Verbeeck[1], J. Royaert[1], E. Geerdens[4,5], C. Vicente[4,5], S. Bornschein[4,5], C. J. Harrison[6], J. P. Meijerink[7], J. Cools[4,5], J.D. Dinman[2], K.R. Kampen[1], K. De Keersmaecker[1]

Background: Several somatic ribosome defects have recently been discovered in cancer, yet their underlying oncogenic mechanisms remain poorly understood. Alterations in ribosomal protein genes *RPL5*, *RPL10*, and *RPL22* have been described in ~20% of T-cell acute lymphoblastic leukemia (T-ALL) cases. Whereas *RPL5* and *RPL22* show heterozygous inactivating mutations and deletions, RPL10 contains a clear mutational hotspot at residue arginine 98 (R98), with 8% of pediatric T-ALL patients harboring this RPL10 R98S missense mutation.
Aims: Investigating the pathogenic role of the recurrent R98S mutation in ribosomal protein L10 (RPL10) in T-ALL.
Methods: A label-free quantitative proteomics experiment was performed to screen for differentially expressed proteins in engineered mouse lymphoid Ba/F3 cells expressing RPL10 WT or RPL10 R98S. Differences in protein expression were further validated in hematopoietic cells derived from a transgenic RPL10 R98S knock-in mouse model and in material derived from xenografted T-ALL patient samples.

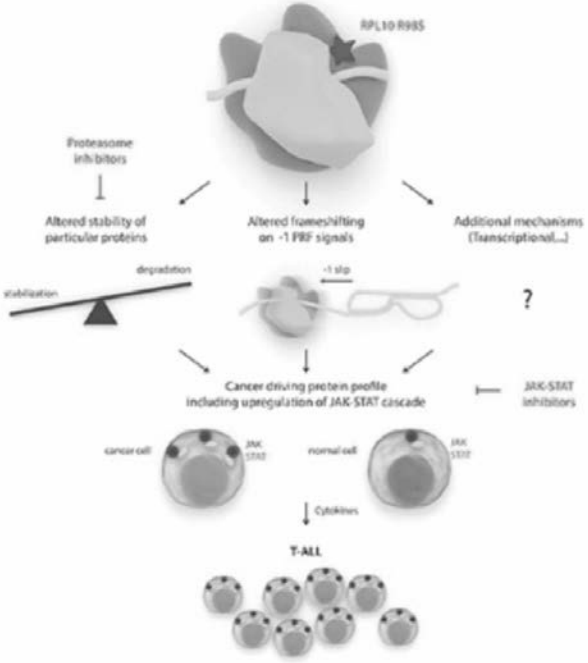

Figure 1.

Results: The differential proteome screen revealed overexpression of several Jak-Stat signaling components (Csf2rb/2, Jak1, Stat1, Stat3, Stat5a/b and Stat6) in engineered RPL10 R98S mouse lymphoid cells, which we confirmed in hematopoietic cells derived from a transgenic RPL10 R98S mouse model. The relevance of this overexpression was illustrated by enhanced Jak-Stat pathway activation upon cytokine stimulation in RPL10 R98S lymphoid cells, as well as increased sensitivity of these cells to clinically used JAK-STAT inhibitors ruxolitinib and pimozide. RPL10 R98S positive leukemia patients likewise showed overexpression of IL7RA, JAK1 and STAT5, increased sensitivity to pimozide, as well as a mutually exclusive mutation pattern between RPL10 R98S and JAK-STAT lesions, suggesting that RPL10-R98S also modulates the cascade in human T-ALL. Programmed -1 ribosomal frameshifting (-1 PRF) recently emerged as a post-transcriptional mechanism regulating expression of cytokine receptors. We identified -1 PRF signals in mouse and human Jak-Stat genes and observed RPL10 R98S associated frameshifting reduction in several of these, which may contribute to their overexpression. Altered levels of -1 PRF can however only partially explain observed JAK-STAT protein expression changes, and transcriptional changes and altered protein stability are also involved. Indeed, our data point to altered proteasome activity and composition in RPL10 R98S cells, with upregulation of immunoproteasome specific catalytic subunits, which may explain the increased stability of particular proteins such as Jak1. Of further medical interest, RPL10 R98S cells showed reduced proteasome activity and enhanced sensitivity to the clinically used proteasome inhibitors bortezomib and carfilzomib.
Summary/Conclusions: We explored the molecular mechanism by which the RPL10 R98S mutation contributes to the pathogenesis of T-ALL. We propose a model in which R98S associated decreases in -1 PRF levels, combined with changes in the degradation of particular proteins and potential other mechanisms such as transcriptional regulation, leads to selective upregulation of the oncogenic JAK-STAT cascade (Figure 1). Besides expanding the relevance of the JAK-STAT cascade in T-ALL and leukemia in general, our results have therapeutic potential since cells harboring the RPL10 R98S mutation are sensitized towards clinically used JAK-STAT and proteasome inhibitors.

NFATC3-PLA2G15 IS A NOVEL INTERGENICALLY SPLICED CHIMERA THAT IS ASSOCIATED WITH AGGRESSIVE T-ACUTE LYMPHOBLASTIC LEUKAEMIA BIOLOGY

J. Bond[1,2,*], C. Trang-Quang[34], A. Bergon[5], M. Belhocine[5], G. Hypolite[1,2], W. Goma[5], J. Ghysdael[3,4], E. Macintyre[1,2], N. Boissel[6], S. Spicuglia[5], V. Asnafi[1,2]

[1]Université Paris Descartes Sorbonne Cité, Institut Necker-Enfants Malades (INEM), Institut national de recherche médicale (INSERM) U1151, [2]Laboratory of Onco-Haematology, Assistance Publique-Hôpitaux de Paris (AP-HP), Hôpital Necker Enfants-Malades, Paris, [3]Institut Curie, PSL Research University, CNRS UMR 3348, [4]Université Paris Sud, Université Paris-Saclay, Orsay, [5]Technological Advances for Genomics and Clinics (TAGC), INSERM U1090, Aix-Marseille University UMR-S 1090, Marseille, [6]Université Paris Diderot, Institut Universitaire d'Hématologie, EA-3518, Assistance Publique-Hôpitaux de Paris, University Hospital Saint-Louis, Paris, France

Background: Transcriptional read-through of a single mRNA between contiguous loci, or *cis*-splicing of adjacent genes (*cis*-SAGe), results in transcription of intergenically-spliced chimeric RNAs (ISCs) in the absence of structural genomic changes. Recent advances in high-throughput RNA-sequencing analysis have permitted identification of aberrant ISC expression as a potential cancer driver, but knowledge of leukaemia-related ISCs is lacking.
Aims: To examine whether *cis*-SAGe generates biologically important ISCs in T-acute lymphoblastic leukemia (T-ALL).
Methods: We performed RNA-sequencing of 12 cases of T-ALL and normal thymic RNA, and used targeted analysis pipelines to detect T-ALL-specific fusion chimeras.
Results: We identified 140 T-ALL-specific fusions, of which 55 involved genes located within 30kb of each other, in the same transcriptional orientation. This distance is consistent with that previously observed for *cis*-SAGE, suggesting that ISC expression is common in T-ALL. In total, putative ISCs were detected in 10/12 samples, with a median of 4 (range 0-15) per patient. We performed further analysis on the candidate ISC *NFATC3-PLA2G15*, which includes the Nuclear Factor of Activated T-cells (NFAT) family member NFATC3, a critical regulator of normal thymopoiesis and known modulator of T-ALL biology. We found that primary T-ALLs exhibited a wide range of *NFATC3-PLA2G15* expression, while levels in normal tissue were either very low or undetectable. 5' RACE PCR analysis of leukemic cDNA revealed that fusion transcription was initiated in exon 1 of *NFATC3*. We also performed array competitive genomic hybridization of 115 diagnostic T-ALL samples, and found no evidence of microdeletions that would result in *NFATC3-PLA2G15* expression, providing strong evidence that *NFATC3-PLA2G15* is a true ISC that is generated by *cis*-SAGe. We found that the NFATC3-PLA2G15 fusion had lower activity than wild-type NFATC3 in both luciferase reporter experiments and proliferation and survival complementation assays in NFAT-null ALL cell lines *in vitro*. Gene set enrichment analysis revealed that primary T-ALL blasts with elevated *NFATC3-PLA2G15* levels had reduced transcription of canonical NFAT target genes *in vivo*, suggesting that these cases may have lower activity of normal physiological NFAT pathways. Strikingly, we found that higher *NFATC3-PLA2G15* levels strongly correlated with both shorter time to leukemia development (p=0.01) and survival (p=0.003) in patient-derived T-ALL xenografts in immunodeficient mice. These findings were corroborated by survival analyses of human T-ALL patients treated as part of the Francophone multinational GRAALL-2003 and -2005 studies, as cases with the highest quartile of *NFATC3-PLA2G15* expression had significantly reduced 5 year overall survival (52.6%, 95% CI 33.3% - 68.7%) compared with *NFATC3-PLA2G15* low cases (69.8%, 95% CI 58.8% - 78.3%, p=0.047).
Summary/Conclusions: Our results suggest that ISC expression is common in T-ALL, and that high expression of the *NFATC3-PLA2G15* ISC correlates with reduced canonical NFAT pathway activity and poor patient outcome.

Thrombotic disorders

S441

ASSESSING THE RISK-BENEFIT OF ANTICOAGULANTS IN ELDERLY PATIENTS WITH CANCER-ASSOCIATED VENOUS THROMBOEMBOLISM: A POPULATION BASED STUDY

A. Lazo-Langner[1,2,*], M. Louzada[1,2], A. Garg[1,2,3], M. McCallum[3], S. Dixon[3]
[1]Epidemiology and Biostatistics, [2]Medicine, Western University, [3]Institute for Clinical Evaluative Sciences, London, Canada

Background: Cancer patients have a higher risk of venous thromboembolism (VTE) which conveys a higher subsequent mortality risk; conversely, they also have a higher risk for bleeding due to many factors including abnormal tumor anatomy and the use of chemotherapy agents with the associated risk for thrombocytopenia. However, the consequences of a recurrent VTE or a major bleeding (MB) event might be different in terms of mortality. As a result, the risk of VTE recurrence or a MB event might bear different weights. A previous systematic review has suggested that the case fatality rates of VTE recurrence and MB are similar. However, heterogeneity in study design, outcomes and in particular the types of populations included, limited the interpretation and applicability of the results. Clinical decision making uses estimations of risk and benefit for any given intervention. In the case of VTE, anticoagulants are the cornerstone of treatment having a proven benefit in reducing the risk of recurrent VTE events with an associated increase in the risk of bleeding. Therefore, determining the risk-benefit of anticoagulants might allow for better informed treatment decisions, in particular in a population at high risk for both ends of the spectrum. Therefore, herein we sought to estimate the risk and benefit of anticoagulant therapy in cancer patients developing a VTE using data from administrative databases.
Aims: To estimate case fatality rates of VTE recurrence and MB, as well as the case fatality rate-ratio for MB and VTE recurrence in cancer patients developing a VTE treated with anticoagulants.
Methods: We conducted a retrospective population-based cohort study in Ontario, Canada using de-identified linked administrative healthcare databases housed at the Institute for Clinical Evalutive Sciences (ICES). We included patients over 65 years of age with a diagnosis of cancer defined using provincial, ICD-9 and ICD-10 codes for major malignancies and who developed a VTE event within 6 months of the initial cancer diagnosis. VTE was identified through a previously validated algorithm using a combination of diagnostic codes for deep vein thrombosis (DVT) and pulmonary embolism (PE) and codes identifying diagnostic procedures for VTE (i.e. ultrasound, CT pulmonary angiography, lung scintigraphy) within 7 days of each other. Recurrent VTE and MB events were assessed within 180 days from the index date. MB was identified using a previously validated algorithm and included upper and lower gastrointestinal and intracranial bleeding events. Treatment was classified based on the first available prescription within 7 days of the index VTE. We estimated mortality within 7 days of the VTE recurrence or MB events using an unadjusted Cox proportional hazards model and competing risk analysis. Ratios of the mortality for MB compared to VTE recurrence were calculated and 95% confidence intervals were estimated using non-parametric models.
Results: Between 2004 and 2014 there were 6967 VTE events identified in cancer patients over 65 years of age and treated with an anticoagulant. Mean age was 75 years, and 47.6% patients were women. Of all patients, 59.9% received prescriptions for LMWH alone, 15.3% for LMWH followed by warfarin, 22.1% for warfarin and 2.7% for rivaroxaban. At 180 days after the index VTE event there were 235 (3%) MB events and 1184 (17%) VTE recurrences. Within 7 days of the outcome event there were 26 (11%) deaths after MB and 6 (0.5%) after VTE. The mortality ratio for MB *versus* VTE was 21.8 (95% CI 9-53). In exploratory analyses we did not find differences according to type of anticoagulant prescription.
Summary/Conclusions: In cancer patients 65 years or older treated with anticoagulants for a VTE, the 7 days mortality after a MB event is at least 9 times higher than after a VTE recurrence, although the estimate is imprecise. This data should be taken into consideration when designing studies and interventions involving anticoagulant therapy in this population.

RISK OF THROMBOSIS IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA: A POPULATION-BASED COHORT STUDY

A.M. Birgisdóttir[1,*], I.S. Sverrisdóttir[1], O. Landgren[2], M. Björkholm[3], S.Y. Kristinsson[1,3]
[1]Faculty of Medicine, University of Iceland and Landspitali University Hospital, Reykjavik, Iceland, [2]Department of Medicine, Myeloma Service, Memorial Sloan –Kettering Cancer Center, New York, United States, [3]Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden

Background: Lymphoma is a malignancy that originates in lymph nodes and lymphoid tissue. The main category of lymphomas is non-Hodgkin's lymphoma (NHL). NHL comprise about 3% of all cancers in Sweden. Some are aggressive and fast growing, while others are more indolent and do not necessarily require treatment. It is well known that cancer increases the risk of thrombosis, especially venous thromboembolism, but data are scarce on the risk of thrombosis in NHL patients.
Aims: The aim of this study is to evaluate the risk of thrombosis in NHL patients compared to controls and to study time trends in the risk of thromboembolism with recent advances in the treatment of these diseases.
Methods: The study population consisted of individuals diagnosed with NHL in Sweden 1980-2013 (n=40,354), and up to four matched controls (n=115,677). The risk of the first thrombosis was evaluated after the diagnosis of NHL (and corresponding date for controls) and the ones that occurred less than 30 days prior to diagnosis of NHL. Kaplan-Meier survival analysis was used to estimate the risk of thrombosis and a log-rank test performed to assess statistical significance. Cox regression analysis was used to calculate hazard ratios (HRs) and 95% confidence intervals (CI) (adjusting for age, sex, year of diagnosis, and previous history of thrombosis). Risk of deep vein thrombosis, pulmonary embolism and arterial thrombosis was evaluated. Arterial thrombosis was defined as cerebral infarct, transient ischemic attack, angina pectoris, myocardial infarction, and arterial embolism and thrombosis.
Results: NHL patients had a statistically significant increase in risk of any type of thrombosis compared to controls (HR: 1.58, 95% CI: 1.53-1.62). The risk was significantly increased for all three types of thrombosis; deep vein thrombosis (HR: 3.11; 95% CI: 2.93-3.31), pulmonary embolism (HR: 3.16; 95% CI: 2.95-3.39) and arterial thrombosis (HR:1.20; 95% CI: 1.16-1.23). The risk of thrombosis did not change during the study period for the NHL patients. There was an increased risk of thrombosis for NHL patients when compared to controls, independent of previous history of thrombosis (HR: 1.64; 95% CI: 1.59-1.69 if no previous history, HR: 1.43; 95% CI: 1.37-1.50 if previous history of thrombosis). The incidence of thrombosis for NHL patients started to increase about five months before the diagnosis of NHL, and reached its peak a month before diagnosis. The incidence stayed increased for the first year after diagnosis.
Summary/Conclusions: In this large, population-based, study based on more than 40,000 patients with NHL and almost 116,000 controls, we demonstrated that there is an increased risk of thrombosis in patients with NHL when compared to controls. This is true for all types of thrombosis. We therefore conclude that hypercoagulability seems to increase with diagnosis of NHL. Several factors may contribute to this prothrombotic state, including chemotherapy and other treatment related factors as well as the disease itself. Considering that the increase in the incidence of thrombosis was highest before and around the time of diagnosis for NHL patients, that indicates that the tumor itself may have a great impact on the hypercoagulability of these patients.

COMPARATIVE ANALYSIS OF PREDICTIVE MODELS FOR THROMBOEMBOLIC EVENTS IN LYMPHOMA PATIENTS

D. Antic[1,*], N. Milic[2], S. Nikolovski[1], M. Todorovic[1], J. Bila[1], P. Djurdjevic[1], B. Andjelic[1], V. Djurasinovic[1], A. Sretenovic[1], M. Smiljanic[1], V. Vukovic[1], J. Jelicic[1], B. Mihaljevic[1]
[1]Clinic for hematology, Clinical Center of Serbia, [2]Medical school Belgrade, Belgrade, Serbia

Background: Actual guidelines recommend Padua and Khorana score for thromboembolic (TE) risk estimation for cancer patients in general. These existing models are quite limited for designation of lymphoma patients for TE events, as their development is not based on features specific for hematological patients.
Aims: The aim of this study was to compare diagnostic performance of these suggested predictive models, as well as Thrombosis lymphoma (Throly) score, developed by our group, which is more specific for lymphoma patients.
Methods: The study population included all consecutive patients with a confirmed diagnosis of non-Hodgkin lymphoma (NHL), Hodgkin lymphoma (HL), and chronic lymphocytic leukemia (CLL)/ small lymphocytic lymphoma (SLL), who were treated in the Lymphoma Departments of Clinical Center Serbia and Clinical Center Kragujevac in period from 2006 to 2014. Data for newly diagnosed and relapsed patients who had completed a minimum of one chemotherapy cycle were prospectively collected for all venous and arterial TE events from time of diagnosis to 3 months after the last cycle of therapy. Data for specific demographic, clinical, and laboratory variables known to be associated with TE from Padua and Khoranapredictive scores were also extracted. Moreover, potential disease-related risk factors were gathered. The study population was divided based on a split-sample random method into the model developing

and validation cohorts. The ThroLy model was developed using data solely from a derivation cohort, which included 1236 patients. Variables were evaluated by univariate logistic regression analysis, while the model was developed using a stepwise multivariate logistic regression analysis. Once a final model was defined, patients were divided into *low risk* and *at risk* groups. The final model was assessed in the validation cohort (584 patients). The studied population was also divided, based on Khorana and Padua score, into *low risk* and *at risk* groups.

Results: The study population included 1820 eligible lymphoma patients. The mean patient's age was 53.1 years (range, 15–87 years). Most patients (83%) were newly diagnosed and had advanced stage disease: Ann Arbor stage III, 14.7% and stage IV, 44%. A total of 778 patients (42.7%) had high-grade lymphoma; 351 (19.3%) had low-grade lymphoma; 266 (14.6%) had HL; 156 (8.6%) had other forms; and 269 (14.8%) had CLL/SLL. Of all the patients included in the study, 99 (5.4%) developed at least one TE during the follow-up period. There were 73 patients with venous TE (73.7%), and 25 with arterial TE (25.3%), while 1 patient had both. Patients with aggressive NHL had significantly higher odds of developing TE compared to patients with any other lymphoma type (RR=1.5; 95% CI for RR 1.1–2.4; p=0.027). The incidence of thromboembolism was 81 (5.3%) in the newly diagnosed patients and 18 (6.2%) in relapsed patients. Overall, 35.4% (35/99) of the patients with thromboembolism experienced the event before the start of chemotherapy. The majority of patients (64.6%) had TE events during chemotherapy or within 3 months after chemotherapy. For patients classified *at risk* according to ThroLy score in derivation cohort, the model produced negative predictive value (NPV) of 98.5%, positive predictive value (PPV) of 25.1%, sensitivity of 75.4%, and specificity of 87.5%. In validation cohort PPV for Throly score was 28.9%. Padua and Khorana score had PPV of 15.5% and 14.8% in derivation, and 11.5% and 14.8% in validation cohort, respectively.

Summary/Conclusions: Lymphoma patients are at increased risk of thromboembolic events but thromboprophylaxis in these patients is largely underused. ThroLy score is more specific for lymphoma patients than suggested Padua and Khorana score, but external validation in large prospective cohort studies is required.

Table 1.

Table 1. Clinical features in Group1, Group 2 and both.

	GROUP 1 (n= 782) (March 2014- June 2015)	GROUP 2 (n=469) (July 2015- December 2016)	BOTH (n=1251)	p
Sex (male/female) (%)	58.5/41.5	57.4/42.6	58.0/42	n.s
Mean Age (years)	61.8+/-13.2	61.9 +/-13.6	61.9+/-13.4	n.s
Advanced tumour stage (%)	50.4	60.6	54.0	0.0009
Mean platelets (x10E9/L)	232+/-126	224+/-132	232+/-128	n.s

Chemotherapy (%)	82.9	84.9	83.6	n.s
Type of tumour (Hematologic/non Hematologic %)	21.6/78.4	19.6/80.4	20.8/79.2	n.s
Mean Hospital stay (days)	4 (1-140)	6 (1-101)	5 (1-140)	
≥4 days	419 (53.6%)	325 (69.4%)	744 (59.4%)	<0.0001
Risk score (Pretemed)	5 (3-13)	5 (3-13)	5 (3-13)	n.s

Summary/Conclusions: The new e-alert system further increases the use of VTE prophylaxis in hospitalised cancer patients, although this was not associated with a reduction in the VTE incidence. A relevant number of VTE events occur despite prophylaxis with standard LMWH. Identificaton of risk factors for thromboprophylaxis failure is needed.

This work has been funded by a biomedical research grant with the Laboratory of Pharmaceutical ROVI and an aid to the research projects of the Instituto de Salud Carlos III and the FEDER (PI13 / 01029).

IMPACT OF A NEW ELECTRONIC ALERT SYSTEM (V2.0) FOR VENOUS THROMBOEMBOLISM PREVENTION IN HOSPITALISED CANCER PATIENTS

R. Figueroa[1,*], A. Alfonso[1], V. Sara[1], M.C. Nicolás[1], M. Marcos Jubilar[1], J. López Picazo[2], I. Gil-Bazo[2], A. García-Mouriz[3], J.A. Páramo[1], J. Hermida[4], R. Lecumberri[1]

[1]Hematology, [2]Medical Oncology, [3]Informatics Department, Clínica universidad de Navarra, [4]Division of Cardiovascular Sciences, Centro de Investigación Médica Aplicada, Pamplona (Navarra), Spain

Background: Onco-hematologic hospitalised patients constitute a group at high risk of venous thromboembolism (VTE). Current clinical practice guidelines recommend prophylaxis with low molecular weight heparin (LMWH) during hospitalisation, unless contraindicated. However, its underuse is a worldwide problem. Electronic alert systems (e-alerts) can improve the use of appropriate thromboprophylaxis and reduce the incidence of VTE.

Aims: To evaluate the impact of a new version (v2.0) of our e-alert system for VTE prevention compared with the initial software version. Secondary endpoints try to identify predictive factors for prophylaxis use and thrombotic events.

Methods: Prospective study including consecutive adult cancer patients admitted at our centre. From April 2014 to June 2015 (first period) the initial e-alert system version remained operative and from July 2015 to December 2016 (second period) the new version was active. The v2.0 displayed a second window that asked physicians about the reason why LMHW was not prescribed. The main outcomes were: VTE (confirmed by objective methods), clinically relevant bleeding, and mortality. All patients were followed-up during hospitalisation and 30 days after discharge. Descriptive statistical analysis and correlation between clinical variables and main outcomes were performed by using the software package SSPS v20.

Results: 1251 patients were included, 782 patients in the first period and 469 in the second one (main clinical features are shown in Table 1). E-alerts v2.0 was associated with an increase of appropriate LMWH prophylaxis during hospitalisation (65.2% *vs* 72.2%; p=0.015). However, this improvement did not result in a reduction of VTE during admission or follow-up (2.3% *vs* 2.3%; p=0.89). Interestingly, almost 80% of VTE events occurred despite LMWH use. No differences in the rate of major bleeding (2.8% *vs* 3.2%; p=0.83), and mortality (10.6% *vs* 14.3%; p=0.07) were observed, either. The main reason for not prescribing LMWH prophylaxis was bleeding risk, but in 17% of cases physicians did not consider that the patient really had a high VTE risk. No significant correlation was found between any of the clinical variables analyzed and the risk of VTE. Prophylaxis use was more frequent among patients with solid cancer (vs hematologic), advanced stage, active chemotherapy treatment and longer hospital stay.

IDENTIFICATION OF A NEW AND RELATIVELY FREQUENT SERPINC1 GENE DEFECT CAUSING ANTITHROMBIN DEFICIENCY HARDLY DETECTED BY CURRENT MOLECULAR METHODS: DUPLICATION OF EXON 6

M.E. De La Morena-Barrio[1,2,*], B. de la Morena-Barrio[1], J. Padilla[1], R. Teruel[1,2], S. Asenjo[3], E. Wypasek[4], A. Miñano[1], V. Vicente[1,2], J. Corral[1,2]

[1]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, [2]Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III (ISCIII), Murcia, [3]Servicio de Hematología, Hospital Clínico San Carlos, Madrid, Spain, [4]The John Paul II Hospital, Kraków, Poland; Institute of Cardiology, Jagiellonian University Medical College, Krakow, Poland

Background: Antithrombin (AT) deficiency was the first thrombophilia described 50 years ago and so far the strongest one. Up to 78% of cases are explained by point mutations or small deletion/insertions in exons or flanking regions of *SERPINC1* that are easily detected by sequencing analysis. A low proportion of cases (2%) is explained by gross gene defects, mainly deletions, which are detected by multiplex ligation-dependent probe amplification (MLPA) analysis. However, the molecular base of AT deficiency is unknown using current methods in 20% of cases.

Aims: To identify new *SERPINC1* defects causing AT deficiency.

Methods: We studied 271 unrelated cases with AT deficiency. Functional and biochemical assays characterized plasma AT. Genetic analyses involved Sanger and Next Generation Sequencing (NGS) (PGM, Ion Torrent), MLPA and specific PCR designs.

Results: Sanger sequencing of PCR amplicons with primers flanking the 7 exons and further analysis with SeqscapeTM detected pathogenic mutations in 173 cases. Whole gene sequencing identified 5 mutations in regulatory regions. MLPA analysis revealed 5 cases with whole or partial deletion of the gene. Moreover, 13 cases had disorders of glycosylation. Interestingly, the analysis of the PCR product and the electropherogram of exon 6 of a 42 year-old male patient (P1) with deep venous thrombosis and 75% of anti-FXa activity

with no apparent gene defect by either Sanger sequencing of 7 exons or by NGS analysis of the whole gene using the Ion Torrent platform, revealed a 193 bp insertion, which corresponded to a tandem duplication involving exon 6. Family studies revealed the same duplication in 5 relatives, all with AT deficiency (60-75%). The first MLPA analysis of this case failed to detect the duplication and only after a fine readjustment, it was detected. MLPA analysis under the new conditions of the remaining 59 cases with unknown molecular base for their AT deficiency identified one additional case, P2, with potential duplication of exon 6. P2 was a 17 year-old female with 41% of anti-FXa activity, who developed deep venous thrombosis. Sanger and NGS sequencing also failed to detect any genetic defect in P2. A set of primers specific to detect tandem duplications of exon 6 was designed with forward primer from 3' end of exon 6, and reverse primer from 5' of exon 6. This set of primers only rendered amplification in the two cases with exon 6 duplication. The second patient (P2) had a new 863 bp duplication in tandem of exon 6. Sanger sequencing of the specific amplicons in the two cases with tandem duplication of exon 6 revealed Alu sequences surrounding these duplications. Finally, one out of 5 cases with gene deletions involved breakpoints affecting intron 5 (deletion of exons 2-5).
Summary/Conclusions: Our study identified a new and relatively frequent *SERPINC1* gene defect causing AT deficiency that is hardly identified by current molecular methods: duplication of exon 6. This genetic defect was detected in 1% of our cohort, and represents nearly half of the total gross gene defects causing AT deficiency. The small size of this exon makes difficult the identification of this defect by MLPA. The presence of 6 Alu elements up and downstream exon 6 makes this region a hotspot for unequal recombination that may cause deletions, tandem duplications and potentially transpositions, which may produce AT deficiency (both severe and mild) by an aberrant splicing. We also developed a simple and specific method to detect duplications in tandem of exon 6.

CYTOSOLIC NUCLEIC ACID SENSORS PROMOTE INTESTINAL EPITHELIAL INTEGRITY DURING ACUTE TISSUE DAMAGE AND PROTECT FROM GRAFT-VERSUS-HOST DISEASE

J.C. Fischer[1], G. Eisenkolb[1], M. Bscheider[1], A. Wintges[1], C. Peschel[1], C.A. Lindemans[2], A.M. Hanash[3], R. Jenq[3], J. Dudakov[4], T. Haas[1], M.R. van den Brink[3], H. Poeck[1,*]
[1]3. Medizinische Klinik; Klinikum Rechts der Isar, Technische Universität München, München, Germany, [2]Pediatric Blood and Bone marrow Transplant Program, University Medical 20 Center Utrecht,, Utrecht, Netherlands, [3]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, [4]Clinical Research Division, Fred Hutchinson 44 Cancer Center, Seattle, United States

Background: The epithelial lining of the gastrointestinal (GI) tract represents the first line of defense mediating protection from microbial challenge. Next to producing antimicrobial molecules, Paneth cells contribute to this defense by providing a supportive niche for intestinal stem cells (ISCs) maintaining the epithelium. Loss of intestinal barrier function by total body irradiation (TBI) or chemotherapy (CTx) is an essential step in enhancing the development of inflammatory disease associated with epithelial surface such as graft versus-host disease (GVHD) after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Our current limited ability to protect epithelium and promote regeneration in GVHD is at least in part due a limited understanding of ISC function and epithelial regeneration in the allo-HSCT setting. Recent work suggests a protective function of Type I Interferons (IFN-I) at epithelial surfaces and in the preventon of GVHD. Yet, the molecular pathways that trigger those functions during acute tissue damage are poorly understood. Given that the RIG-I-MAVS and STING pathways are important regulators of IFN-I production and IFN-Is can initiate epithelial repair, we hypothesized that activation of these pathways during conditioning therapy may protect epithelial integrity and could be exploited interventionally to promote intestinal barrier function and prevent GVHD.
Aims: We aimed at characterizing the role of of RIG-I/MAVS and STING during allo-HSCT, and at understanding mechanisms by which activation of these pathways can promote barrier function to enhance healing after genotoxic tissue damage.
Methods: We used an integrated approach with pathophysiologic mechanistic studies on IECs in experimental mouse models (MHC-mismatched and minor histocompatibility antigen (miHA)-mismatched transplants to model highly aggressive GVHD; genotoxic stress induced by TBI and CTx) and evaluation of immune-mediated regenerative strategies to promote epithelial barrier function (organoid cultures, barrier function test)
Results: Mice lacking MAVS were more sensitive to total body irradiation (TBI)- and chemotherapy induced intestinal barrier damage, and, like RIG-I-deficient mice, developed worse graft transplantation (allo-HSCT). This phenotype was not associated with changes in the intestinal microbiota, but with reduced epithelial integrity and regeneration. Conversely, targeted activation of the RIG-I pathway during damage promoted these processes and ameliorated GVHD. Mechanistically, IFN-I (RIG-I-induced or recombinant) could promote growth of intestinal organoid cultures and production of RegIIIγ. Importantly,our findings were not confined to RIG-I/MAVS signaling, as interventional engagement of the STING pathway also protected from loss of barrier function and GVHD and led to IFN-I-dependent intestinal organoid growth. Consistent with this, STING-deficient animals suffered from worse GVHD.
Summary/Conclusions: Our studies may have the potential to develop novel targeted therapies (i) to promote intestinal barrier integrity, (ii) to prevent the development of GVHD, and (iii) for the regenerative response of other tissues.

S447

CD4 T CELLS RECOGNIZING MISMATCHED HLA-DP AFTER ALLOGENEIC STEM CELL TRANSPLANTATION SHOW TISSUE SPECIFIC REACTIVITIES

P. van Balen[1,*], W. de Klerk[1], M. van de Meent[1], C. J. Halkes[1], I. Jedema[1], J. Falkenburg[1]
[1]Hematology, Leiden University Medical Center, Leiden, Netherlands

Background: Expression of HLA class II molecules is under non-inflammatory conditions predominantly restricted to hematopoietic cells. However, donor CD4 T cells directed against mismatched HLA-DP can cause Graft-versus-Host Disease (GVHD) after allogeneic stem cell transplantation (alloSCT) or donor lymphocyte infusions from HLA 10/10 matched but HLA-DP mismatched donors due to upregulation of HLA class II expression under inflammatory conditions. It is often assumed that allo-HLA-DP directed CD4 T cells recognize peptides encoded by household genes presented in foreign HLA-DP and that every cell that expresses the mismatched HLA-DP allele is a target for these T cells. However, *in vitro* experiments illustrated that allo-HLA-DP directed CD4 T cells were not always recognizing patient derived fibroblasts induced to express HLA-DP. We hypothesized that HLA-DP directed CD4 T cells can have tissue specificity if the presented peptides in HLA-DP are encoded by genes with tissue specific expression.

Aims: The aim of the study is to investigate whether donor CD4 T cells recognizing mismatched HLA-DP show tissue specific reactivities.
Methods: In a randomized clinical trial we treat patients 3 months after T cell depleted alloSCT from HLA 10/10 matched, HLA-DP mismatched, donors with 0.25-0.50 x 10^6/kg donor CD4 T cells to promote immune reconstitution. In 4 patients, Graft-versus-Leukemia reactivity and/or organ specific GVHD occurred after the infusion. To characterize the immune responses in these patients, *in vivo* activated T cells were clonally isolated and tested for reactivity against a panel of target cells, including patient and donor derived hematopoietic cells, third party hematopoietic cells as well as different GVHD target cells (patient skin fibroblasts, third party colon carcinoma cells, biliary epithelial cells and lung fibroblasts) expressing the mismatched, patient variant, HLA-DP molecule.
Results: Allo-HLA-DP directed CD4 T cells showing differential recognition of target cells were found in all 4 patients. A total of 33 HLA-DPB1*04:01 reactive CD4 T cell clones were isolated from patient 1 who suffered GVHD of skin and colon, but not liver. Within these 33 clones, 3 clones recognized only hematopoietic target cells, 9 clones recognized hematopoietic, skin and colon derived target cells and 5 clones recognized hematopoietic and colon derived cells only. None of the T cell clones recognized biliary epithelial cells. From patient 2 total of 230 HLA-DPB1*03:01 reactive CD4 T cell clones were isolated, of which 27 recognized only hematopoietic target cells and 96 clones also recognized GVHD target cells with differences in tissue specificity. 32 HLA-DPB1*03:01 reactive T cell clones were found from patient 3, of which 6 recognized only hematopoietic target cells, whereas other clones again showed various tissue specificities. From patient 4, 26 HLA-DPB1*01:01 reactive T cells could be isolated which all recognized biliary epithelial cells with or without co-recognition of other target cells. In addition, also 11 HLA-DPB1*03:01 reactive T cells were isolated, again with different tissue specificities.
Summary/Conclusions: These results illustrate that donor CD4 T cells directed against mismatched HLA-DP show differential recognition of target cells including restricted specificity for cells of hematopoietic origin. Donor CD4 T cells recognizing hematopoietic target antigens in the context of patient specific HLA-DP alleles can be used to mediate tumor specific immune responses after HLA 10/10 matched unrelated stem cell transplantation.

S448

MESENCHYMAL STROMAL CELLS STIMULATE THE PROLIFERATION AND IL-22 PRODUCTION BY TYPE 3 INNATE LYMPHOID CELLS

V. Van Hoeven[1,2,*], J. M. Munneke[1,2], A. Cornelissen[3], S. Omar[2], M. Spruit[2], M. Kleijer[3], J. Bernink[2], B. Blom[2], C. Voermans[3], M. Hazenberg[1,2]
[1]Department of Hematology, [2]Department of Experimental Immunology, Academic Medical Center Amsterdam, [3]Department of Hematopoiesis, Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands

Background: Infusion of mesenchymal stromal cells (MSCs) is a promising and increasingly applied therapy for patients who suffer from graft-versus-host disease (GvHD), a common and life-threatening complication of allogeneic stem-cell transplantations (ASCT). The therapeutic effect of MSCs is mainly ascribed to their suppression of (alloreactive) lymphocyte proliferation and enhancement of tissue-repair activity. However, only about half of the GvHD patients benefit from MSC therapy, and which factors determine MSC responsiveness is unclear. We recently observed that relatively high frequencies of activated type 3 innate lymphoid cells (ILC3s) before and/or after ASCT were associated with a lower risk to develop GvHD, which may be related to the production of tissue-protective IL-22 by ILC3s.

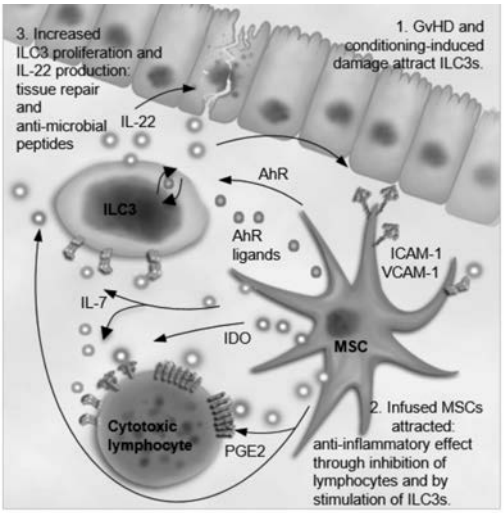

Figure 1.

Aims: To investigate if ILC3s can contribute to the therapeutic effect of MSCs, we studied the interaction between MSCs and ILC3s *in vitro*.
Methods: ILC3s isolated from human tonsils were CellTrace-labeled and co-cultured with bone-marrow derived MSCs for 5 days in the presence of IL-2.
Results: Co-culture with MSCs significantly enhanced the proliferation of ILC3s and their IL-22 production. Reciprocally, ILC3s promoted ICAM-1 and VCAM-1 expression on MSCs. Transwell experiments revealed that for both directions, the interaction is mainly dependent on cell-cell contact or close proximity of MSCs and ILC3s. Addition of blocking antibodies against ICAM-1, VCAM-1, or their integrin ligands, did not affect ILC3 proliferation, suggesting that ILC3 stimulation is ICAM/VCAM independent. Soluble factors also contributed to the interaction, as ILC3s proliferated slightly better in the presence of MSC culture supernatant compared to IL-2 only. Based on experiments with blocking antibodies, we found IL-7 to be the likely candidate for this effect.
Summary/Conclusions: We show that via cell-cell contact and IL-7, MSCs promote the proliferation and IL-22 production by ILC3s *in vitro*, suggesting ILC3s may play a role in the control of GvHD upon MSC therapy.

S449

ABERRANT T CELL RESPONSES IN THE BONE MARROW MICROENVIRONMENT OF PATIENTS WITH POOR GRAFT FUNCTION AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Y. Kong[1,*], Y.-T. Wang[1], X.-N. Cao[1], Y. Song[1,2], Y.-H. Chen[1], Y.-Q. Sun[1], Y. Wang[1], X.-H. Zhang[1], L.-P. Xu[1], X.-J. Huang[1,2]
[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Poor graft function (PGF) remains a life-threatening complication following allogeneic hematopoietic stem cell transplantation (allo-HSCT), and the underlying mechanisms have not yet been elucidated. Considerable evidence from murine studies has demonstrated that effective hematopoiesis depends on the specific bone marrow (BM) microenvironment, where hematopoietic stem cells reside. In this regard, we previously reported that PGF patients had impaired BM endosteal and vascular microenvironment (***BBMT*** 2013; ***BMT*** 2016; ***Oncotarget*** 2016; ***Blood*** 2016). Moreover, our pilot study found that both $CD4^+$ and $CD8^+$ T cells were polarized towards a type 1 immune response in the BM microenvironment of PGF patients (N=10) compared to those in matched good graft function (GGF) patients(N=20) (***BBMT*** 2016). Nevertheless, whether abnormalities of T cell subsets in the BM immune microenvironment, including Th17, Tc17, Th1, Tc1, Th2, Tc2 cells and regulatory T cells (Tregs), are involved in the pathogenesis of PGF remains to be explored.
Aims: To compare the T cell subsets in the BM immune microenvironment, including Th1, Tc1, Th2, Tc2, Th17, Tc17 cells and Tregs, between patients with PT and GGF after allo-HSCT.
Methods: This prospective nested case-control study enrolled 20 patients with PGF, 40 matched patients with good graft function (GGF) after allo-HSCT, and 20 healthy donors (HD). Th17, Tc17, Th1, Tc1, Th2, Tc2 cells, Tregs and their subsets were analyzed by flow cytometry. The study was approved by the Ethics Committee of Peking University People's Hospital, and written informed consent was obtained from all the patients before study-entry in accordance with the Declaration of Helsinki.
Results: The demographic and clinical characteristics were similar between allo-HSCT patients with PGF and those with GGF. The percentages of Th1 (37% *vs.* 26.4%, P=0.0005) and Tc1 (52.4% *vs.* 19%, P<0.0001) cells were significantly higher in PGF patients than in GGF patients, whereas the percentages of Th2 (0.8% *vs.* 2.4%, P<0.0001) and Tc2 (0.5% *vs.* 1.1%, P<0.0001) cells were markedly lower in the PGF group than in the GGF group. PGF patients showed significantly greater Th1 cell/Th2 cell (31.6 *vs.* 10.8, P<0.0001) and Tc1 cell/Tc2 cell ratios (108.8 *vs.* 18.4, P<0.0001) than those for GGF patients. Moreover, a significantly higher proportion of stimulated $CD4^+$ T cells that produced IL-17 (Th17) was found in the BM of PGF patients than in the BM of GGF patients and HD (3.7% *vs.* 1.6% *vs.* 1.1%, P<0.05), whereas the percentages of Tregs in PGF patients were comparable to those in GGF patients and HD, resulting in a dramatically elevated ratio of Th17 cells/Tregs in the BM of PGF patients relative to those in GGF patients (1.01 *vs.* 0.57, P=0.04).
Summary/Conclusions: The present study revealed that aberrant T cell responses in the BM immune microenvironment may be involved in the pathogenesis of PGF after allo-HSCT. These findings will facilitate the optimization of immune regulation strategies and improve the outcome of PGF patients post-allotransplant.

S450

HIGHER FREQUENCY OF SWITCHED MEMORY B CELLS PREDICTS THE INCIDENCE OF CHRONIC GRAFT-VERSUS-HOST DISEASE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

R.M. Saliba[1,*], H.W. Song[2], O.M. Maher[3], B.J. Overman[1], C.J. Hofferek[2], A.V. Pham[2], J. Chen[1], E. Shpall[1], I.F. Khouri[1], R.E. Champlin[1], B. Oran[1], S. Ahmed[1], A.M. Alousi[1], D.Q. Tran[2]
[1]Stem Cell Transplantation and Cellular Therapy, The University of Texas MD

Anderson Cancer Center, [2]Allergy / Immunology, UTHealth McGovern Medical School, Houston, [3]Division of Pediatrics, Dana-Farber Cancer Institute, Boston, United States

Background: Aberrant B-cell homeostasis has been described in patients (pts) with chronic graft-versus-host disease (cGVHD) following allogeneic stem cell transplantation (allo-SCT). However, there is no information on the predictive value of specific B-cell subsets of the incidence of cGVHD.
Aims: We sought to determine if B-cell subsets measured around day 100 after allo-SCT predict the subsequent occurrence of cGVHD in a prospective clinical study.
Methods: Peripheral blood (PB) samples were obtained from consented patients (pts) between day 80 and 110 (D100) after allo-SCT at The University of Texas MD Anderson Cancer Center from 2012 to 2015. Only pts who had not been diagnosed with cGVHD or progression of underlying malignancy by D100 were eligible for this study. We analyzed CD19+CD20+ B cell subsets by FACS. Subsets were defined as naïve (CD27-IgD+), unswitched (CD27+IgD+) and switched (CD27+IgD-) memory cells. Receiver Operating Characteristic (ROC) curve was used to identify threshold levels of B cell % and numbers that predict the incidence of cGVHD. cGVHD diagnosis was based on the 2014 National Institutes of Health guidelines.
Results: A total of 80 pts were enrolled in the study. The median age at SCT was 49 years (range 21-75). The majority (80%) of pts received myeloablative conditioning, and 75% received tacrolimus with methotrexate or mycophenolate mofetil for GVHD prophylaxis. Diagnosis was myeloid (61%) or lymphoid (34%) malignancy in the majority of pts. Grafts source was primarily PB or bone marrow from matched- unrelated (61%) or related (24%) donors. Grade 2-4 acute GVHD had occurred in 45% of pts before D100. Thirty-six percent of pts were receiving steroids at D100. Forty-seven (59%) pts had detectable (≥0.1%) CD19+CD20+ signal on D100. In this subset, median B cell % was 3 (range 0.25-34) and median absolute number was 23 (1.8-419) $x10^3$ cells /μL. Median % naïve, unswitched, and switched B cells was 89% (54-99), 1.85% (0.3-8.5), and 2.1% (0-30), respectively. A total of 15 pts were diagnosed with cGVHD within 1 year after D100 including 11 with detectable B cells. ROC analysis did not identify predictive thresholds for overall B cell % or numbers. However, it identified predictive thresholds for each of the B cell subsets analyzed. The area under the curve (AUC) analysis indicated that % naïve (cutoff 87.3%) and % switched (cutoff 4%) B cells were the most significant (AUC 86%) predictors of the incidence of cGVHD. Rounding up the cutoff values, we grouped pts into 3 mutually exclusive groups: 1) naïve B cells ≥90% (n=23, none had >5% switched B cells), 2) naïve B cells <90% and switched B cells ≤5% (n=11), and 3) naïve B cells <90% and switched B cells >5% (n=13). Patients (n=33) with undetectable B cells were considered together as one group. The rate of cGVHD after D100 was significantly higher in pts with <90% naïve and >5% switched B cells (HR=7, p<0.001) with a 1-year cumulative incidence of 61% (Figure). None of the characteristics listed above were significantly associated with the rate of cGVHD. Percent naive and switched B cells did not correlate with receipt of steroids on D100. Patients with undetectable B cells were significantly more likely to have an underlying lymphoid *vs* myeloid malignancy (58% *vs* 33%, p< 0.001); and those with ≥90% naïve B cells were significantly more likely to be ≤55 years of age at the time of allo-SCT (83% *vs* 42%, p=0.004).

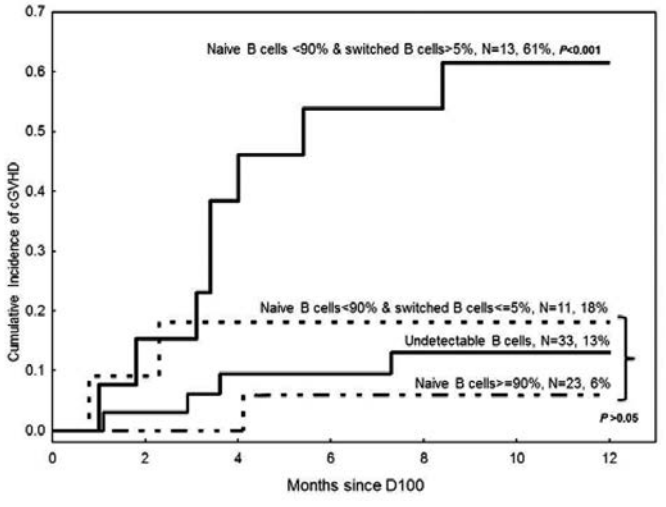

Figure 1.

Summary/Conclusions: In conclusion, D100 frequency of naïve and switched B cells predicts the subsequent development of cGVHD. Lymphoid malignancies and older age may be associated with aberrant B-cell reconstitution. Consideration of D100 B-cell subsets may improve risk stratification models for the development of cGVHD.

Background: Pyruvate kinase (PK) deficiency is a congenital hemolytic anemia caused by deficiency of the glycolytic enzyme, red cell PK (PK-R). AG-348 is an orally available, small molecule, allosteric activator of PK-R that activates the wild-type and a range of mutated PK-R enzymes *in vitro*, and increases PK-R activity and restores adenosine triphosphate levels in red blood cells from patients with PK deficiency *ex vivo*.
Aims: To report on preliminary efficacy and safety data from the use of AG-348 in the ongoing DRIVE PK study (NCT02476916), an open-label dose-ranging trial of AG-348 in transfusion-independent adults with PK deficiency.
Methods: After providing informed consent, patients were randomized to AG-348 50mg or 300mg orally twice daily (BID) for 6 months (Core Period). At the end of the Core Period, patients can continue on treatment for another 2 years in the Extension Period. Transfusion independence is defined as ≤3 units of red blood cells transfused in the 12 months preceding the first dose of AG-348 and no transfusions in the 4 months preceding the first dose. Patients are followed weekly for Weeks 1-3, every 3 weeks for Weeks 4-12, monthly for Weeks 13-24 and then every 3 months until the end of the study. Hormone and iron status are evaluated at Baseline, Week 12 and End of Core Period, and then every 6 months in the Extension Period.
Results: As of 18 Jan 2017, goal enrolment has been met and all 52 patients are evaluable for safety and efficacy; 24 have completed the Core Period and 23 are ongoing in the Core Period. Five patients discontinued from the Core Period, owing to adverse events (AEs) (n=2) or consent withdrawal (n=3). Of the 24 subjects who completed the Core Period, 21 entered the Extension Period and 20 are still on treatment; 1 was discontinued by the investigator. Patients are currently receiving doses ranging between <25mg BID and 300mg BID. As of the previous data cutoff date of 23 Sep 2016 (where N=34), AG-348 had an acceptable AE profile, with headache (44%), nausea (41%) and insomnia (38%) being the most frequently reported events. Serum levels of sex steroids measured at Baseline, Week 12 and Week 24 in the Core Period demonstrated increases in free and total testosterone, and decreases in estradiol and estrone, consistent with the known effect of aromatase inhibition by AG-348. Of the 32 patients evaluable for efficacy at 23 Sep 2016, 15 (47%) had a maximal increase in hemoglobin (Hb) >1 g/dL. Hb responses were seen across a range of four doses, and were rapid and sustained. For a subset of patients (n=8), the rate of glycolytic metabolism in peripheral blood samples was assessed before and after treatment, and a positive correlation was observed between increases in glycolytic flux through the PK-R pathway and increases in Hb. Updates on safety, clinical efficacy measures (including Hb levels) and genotype–response correlations will be provided.
Summary/Conclusions: AG-348 is a novel, first-in-class PK-R activator undergoing clinical testing in patients with PK deficiency. The ongoing DRIVE PK study has now met goal enrolment of 52 patients, and data from these patients will be available at the time of presentation. Chronic daily dosing with AG-348 is well tolerated and has demonstrated clinically relevant, durable increases in Hb across a range of doses from <25mg BID to 300mg BID. These data highlight the potential of AG-348 to be the first disease-altering treatment for patients with PK deficiency.

Hematopoietic Innovative Therapies Division, Centro de Investigaciones Energéticas, Medioambientales y Tecnológicas (CIEMAT), Centro de Investigaciones Biomédicas en Red de Enfermedades Raras (CIBERER), Madrid, Spain

Background: Pyruvate kinase deficiency (PKD) is the most common glycolytic enzyme defect causing hereditary non-spherocytic hemolytic anemia. PKD does not have a specific curative treatment. Therefore treatment is mainly supportive, consisting of regular red blood cell transfusions, splenectomy and chelation therapy for iron overload. This does impact life expectancy and quality of life for affected patients. Hematopoietic allogeneic stem cell transplantation (HSCT) has the potential to cure the disease. However, there is little experience in applying HSCT in PKD and guidelines are not available. To date, only four cases of HSCT have been published. Thus, additional data are required to help the establishment of HSCT guidelines and support future strategies, such as gene therapy.
Aims: The aim of this study was to make a worldwide inventory of all cases of PKD that have been treated by HSCT, and to evaluate indication, procedures employed, and outcome.
Methods: This is an international case series. Queries were send to national and international databanks and to physicians involved in HSCT on PKD patients. The latter were asked to complete a questionnaire on disease characteristics, pre-transplant condition, transplant regimen and post-transplant outcome. Two additional cases were included from a recently published report (Kim. 2016. Bone Marrow Transplantation).

(descriptive statistics: mean-median (range) (N), frequencies number/total (percentage) *P=<0.05			

Results: From 1996 to 2016 a total of 16 PKD-patients were reported to have been treated by stem cell transplantation. Eight patients were treated in the EU and eight in Asian centres, respectively. No patient resulted to be transplanted in the US. Median age at transplantation was 6,5 years. (10 patients (62,5%) were <10 years; 6 (37,5%) >10 years), seven patients (43,8%) were splenectomized at the time of HSCT. Fifteen patients (94%) reached engraftment. The sixteenth patient showed mixed chimerism followed by spontaneous transition to full donor chimerism after splenectomy six months post transplantation. Two patients suffered from secondary graft loss. One of these had recovery to 91% donor chimerism after donor lymphocyte infusion. Outcome in the other patient is unknown. GvHD grade 4 was reported in 6/16 cases (38%). There was no obvious relation between GvHD prophylaxis or any other clinical factors and the occurrence of GvHD grade 2-4 in our patients. Two-year cumulative survival was 74%. Two patients did not reach the two-year milestone yet. All five patients who did not survive died of transplant-related causes. Patients who did not survive were significantly older (p=0.036) and were all treated in a European center (p=0.026) (see Table). Also, they had suffered more often from GvHD grade 2-4 (p=0.031). Nine out of ten patients (90%) younger than ten years old survived transplantation, whereas two out of six (33.3%) patients older than ten survived. Patients younger than ten years old were less often splenectomized (p=0.001). All Asian patients (8/8) survived transplantation, whereas three out of eight European patients survived. Patients treated in Asian hospitals differed from European patients in that they were younger (p=0.001), less often splenectomized (p=0.041) and had a lower ferritin level prior to transplantation (p=0.048). They were more often transplanted with peripheral blood stem cells (p=0.014) and more often conditioned on a cyclophosphamide (p=0.007) regimen.
Summary/Conclusions: This is the first study on outcome of HSCT in PKD patients. Due to the still relatively small number of cases no definite conclusions on the safety of HSCT in PKD can be drawn. However, we observed a better survival for patients transplanted before the age of ten. This difference could also explain difference in survival between patients transplanted in Europe *versus* Asia. The high rate of severe GvHD in this cohort is a reason for concern. The strong decline in survival of patients older than ten years of age indicates the need for very careful selection of HSCT-candidates.

Background: Dehydrated hereditary stomatocytosis, also called hereditary xerocytosis (HX), is a dominant non-spherocytic chronic hemolytic anemia characterized by an increased leak of monovalent cations through the red cell membrane leading to dehydration and a shortened red cell survival. HX is difficult to diagnose because of its rarity and the heterogeneity in its clinical presentation.
Aims: Our study aims to characterize the clinical and biological features at HX diagnosis in a retrospective multicentric series of 103 patients from 49 families.
Methods: HX diagnosis was based on the typical left-shifted curve of osmolar gradient ektacytometry performed at CHU Bicêtre from 1993 to 2016. All patients were from European origin. They were referred to our center for: chronic non-spherocytic hemolysis (30), thrombotic events after splenectomy (8), hyperferritinemia with hemolytic features (5), unexplained perinatal oedema (6) or family study (54) after diagnosis in a first-degree probands. PIEZO1 and KCNN4 were analyzed by Sanger sequencing of the exons and intron-exon junctions.
Results: Clinical features: Most of HX diagnosis was made in adults (median age 31.5 years, range 0-88), children less than 10 years representing only 21% of all cases. 71 patients (69%) were already followed for unexplained hemolysis. Hyperferritinemia and/or a chelation therapy were noticed for 26 patients among the 55 for whom this data was available (47%). 19 patients were treated for iron overload: phlebotomy (14) and/or Deferasirox (6) and/or Deferoxamine (6) and/or Deferiprone (1). A perinatal edema history was noted in 17 (16,5%) patients. A history of thrombotic complication was reported in 12 (11,6%) patients, corresponding to a total number of 17 thrombotic events including post-embolic pulmonary hypertension (2), arterial events (3), pulmonary embolism (4), portal thrombosis (4), splenic infarcts (2) and deep venous throm-

bosis (2). 10 among these 12 patients (83%) were splenectomized, confirming the very high risk of thrombosis after splenectomy in HX. Two patients underwent a thrombotic event without splenectomy: one cerebral stroke and one splenic infarct.

Biological features: The median hemoglobin level was in the normal range: 135±19 g/L (range 71-195) with a slight macrocytosis (median MCV: 99±8fL) and a marked reticulocytosis (median reticulocyte count: 252±141G/L). Of note, 57 patients (55%) presented a totally compensated hemolysis with a hemoglobin level above 115g/L. MCHC was in the normal range (median 35±1,3g/dL) but was above 36 g/dL for 28 (27,1%) patients. Stomatocytes were noticed on the blood smear in 42 patients over 70 available, numbered as rare (19%), few (60%) or numerous (21%). Genetics could be performed in 45 subjects from 22 distinct families. At least one *PIEZO1* mutation was identified in very affected subjects. No *KCNN4* mutations were found in these typical ektacytometric forms of HX.

Summary/Conclusions: This work represents the largest HX series and highlights the important heterogeneity in the clinical features at diagnosis. One important finding is that most patients were not anemic and presented a compensated hemolysis. In a significant percentage of cases, diagnosis was made in the exploration of extra hematological features including perinatal edema or hemochromatosis occurring despite the absence of any red blood cells transfusion. Moreover, we confirmed the very high risk of thrombotic events after splenectomy, underlining the absolute necessity of formally eliminating HX in any unexplained chronic hemolysis each time splenectomy is considered.

S454

CRIZANLIZUMAB, A P-SELECTIN INHIBITOR, INCREASES THE LIKELIHOOD OF NOT EXPERIENCING A SICKLE CELL-RELATED PAIN CRISIS WHILE ON TREATMENT: RESULTS FROM THE PHASE II SUSTAIN STUDY

A. Kutlar[1,*], J. Kanter[2], D. Liles[3], R. Cancado[4], A. Bruederle[5], M. Shi[5], Z. Zhu[6], K.I. Ataga[7]

[1]Sickle Cell Center, Medical College of Georgia, Augusta University, Augusta, [2]Division of Pediatrics, Medical University of South Carolina, Charleston, [3]Division of Hematology-Oncology, East Carolina University, Greenville, United States, [4]Department of Hematology-Oncology, Santa Casa Medical School of São Paulo, São Paulo, Brazil, [5]Novartis Pharma AG, Basel, Switzerland, [6]Novartis Pharmaceuticals, East Hanover, [7]Division of Hematology-Oncology, University of North Carolina, Chapel Hill, United States

Background: Sickle cell-related pain crises (SCPCs) are a substantial cause of morbidity in patients with sickle cell disease (SCD). At a dose of 5.0mg/kg, the P selectin inhibitor crizanlizumab, delivered intravenously every 4 weeks after loading, was shown to significantly reduce the frequency of SCPC events and was well tolerated in the 52-week SUSTAIN study (Ataga KI *et al. N Engl J Med* 2017;376:429-439).

Aims: This *post-hoc* analysis evaluated patients who did not experience a SCPC for the duration of the trial.

Methods: SUSTAIN was a randomized, double-blind, placebo-controlled, Phase II study (NCT01895361). Patients aged 16–65 years with SCD (including HbSS, HbSC, HbSβ^0–thalassaemia, and HbSβ$^+$–thalassaemia genotypes) and 2-10 SCPC events in the previous 12 months were included. Concomitant use of hydroxyurea (HU) was permitted if the patient had been using it for ≥6 months and at a stable dose for ≥3 months. Patients were randomized 1:1:1 to receive intravenous crizanlizumab 5.0mg/kg, 2.5mg/kg or placebo. Loading doses were administered on days 1 and 15, followed by routine treatment every 4 weeks to week 50, with the final assessment visit at week 52. Descriptive statistics were used to summarize the frequency of patients who were SCPC event-free for the duration of the study, based on the intent-to-treat (ITT) population overall and by prior SCPC events, SCD genotype and HU use at baseline.

Table 1.

Table. SCPC event-free patients by prior SCPC events, genotype and HU use

	Crizanlizumab 5.0 mg/kg N=67	Crizanlizumab 2.5 mg/kg N=66	Placebo N=65
SCPC events in the year prior to study			
2–4	17/42 (40.5)	10/41 (24.4)	10/41 (24.4)
5–10	7/25 (28.0)	2/25 (8.0)	1/24 (4.2)
Genotype			
HbSS	15/47 (31.9)	9/47 (19.1)	8/47 (17.0)
Other	9/20 (45.0)	3/19 (15.8)	3/18 (16.7)
HU use			
Yes	14/42 (33.3)	9/41 (22.0)	7/40 (17.5)
No	10/25 (40.0)	3/25 (12.0)	4/25 (16.0)

All data are n/N (%)

Results: Among the 198 patients included in the study (ITT population), 62.6% and 37.4% had experienced 2-4 and 5-10 SCPC events in the previous year, respectively, and 62.1% were taking HU at baseline. HbSS was the most common genotype (71.2%; HbSC: 16.2%, HbSβ^0–thalassemia: 6.1%, HbSβ$^+$–thalassemia: 5.1%, other: 1.5%). Overall, more patients in the crizanlizumab 5.0mg/kg group (n=24/67; 35.8%) were SCPC event-free than in the 2.5mg/kg (n=12/66; 18.2%) and placebo (n=11/65; 16.9%) groups. In each of the prior SCPC events, SCD genotype and HU use subgroups, a greater proportion of patients treated with crizanlizumab 5.0mg/kg were SCPC event-free compared with those in the crizanlizumab 2.5mg/kg or placebo arms (Table 1). In subpopulations considered to be at increased risk of experiencing a SCPC (patients with 5-10 SCPC events in the previous year and/or with the homozygous HbSS genotype), a higher proportion of patients treated with crizanlizumab 5.0mg/kg were SCPC event-free compared with those in the placebo arm (28.0% *vs* 4.2% and 31.9% *vs* 17.0%, respectively). Additionally, 33.3% of patients who were taking HU and treated with crizanlizumab 5.0mg/kg were SCPC event-free during the study, compared with 17.5% in the placebo arm, possibly suggesting an additive effect.

Summary/Conclusions: Treatment with crizanlizumab 5.0mg/kg appears to increase the likelihood of adult patients with SCD being SCPC event-free while on treatment, even in high-risk subpopulations. Crizanlizumab 5.0mg/kg was also effective in those who had experienced at least two SCPCs in the previous year despite taking HU, suggesting that this dose is effective as a disease-modifying agent that meets an unmet medical need.

S455

FREE IRON IN SERA OF PATIENTS WITH SICKLE CELL DISEASE CONTRIBUTES TO THE RELEASE OF NEUTROPHIL EXTRACELLULAR TRAPS

K. Van Avondt[1,*], M. Schimmel[1,2], E. Nur[2], G. van Mierlo[1], I. Bulder[1], R. van Bruggen[3], B.J. Biemond[2], B.M. Luken[1], S. Zeerleder[12]

[1]Department of Immunopathology, Sanquin Research, and Landsteiner Laboratory, AMC, University of Amsterdam, [2]Department of Hematology, Academic Medical Center, University of Amsterdam, [3]Department of Blood Cell Research, Sanquin Research, and Landsteiner Laboratory, AMC, University of Amsterdam, Amsterdam, Netherlands

Background: Chronic hemolysis is a hallmark of sickle cell disease (SCD). Hemolysis in SCD has been associated with elevated levels of heme in the circulation of both human patients and SCD mice. It was shown that TNF-α treatment induces experimental vaso-occlusive crisis (VOC) in SCD mice, associated with the formation of neutrophil extracellular traps (NETs) as shown by staining of lung sections (Chen *et al. Blood* 2014). In addition, the administration of DNase I to degrade NETs led to improved survival. Furthermore, it was shown that plasma from SCD patients obtained during SCD crisis induced NET formation by TNF-α primed neutrophils. Free heme was suggested to mediate the formation of NETs in SCD, as treatment of SCD mice with the heme-binding protein hemopexin (Hpx) to scavenge free heme led to reduced NET formation (Chen *et al. Blood* 2014).

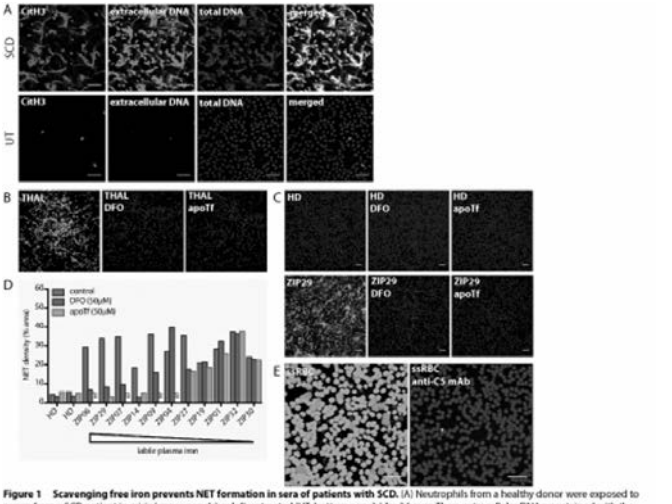

Figure 1 Scavenging free iron prevents NET formation in sera of patients with SCD. (A) Neutrophils from a healthy donor were exposed to serum from a SCD patient in crisis (upper panels) or left untreated (UT, bottom panels) for 3 hours. Then, extracellular DNA was stained with the nonpermeable DNA-binding dye Sytox Green (green). Immunostaining for citrullinated histone H3 (CitH3, red) confirmed the presence of NETs. Cells were counterstained with the cell permeable DNA-binding dye Hoechst 33342 (blue). Merged images (right panels) show co-staining of extracellular DNA with CitH3 when neutrophils were exposed to SCD serum. Scale bar, 50 μm. (B) Neutrophils from a healthy donor were exposed to serum from a thalassemia patient in the presence or absence of deferoxamine (DFO, 50 μM) or apotransferrin (apoTf, 50 μM). Release of extracellular DNA (green in these images) was visualized with confocal fluorescence microscopy using 2 DNA-binding dyes, one cell impermeable (Sytox Green) and the other cell permeable (Hoechst 33342, blue). (C) Neutrophils from a healthy donor were exposed to SCD serum in the presence or absence of DFO or apoTf. Release of extracellular DNA was visualized as in (B). Scale bar, 50 μm. (D) In 3 independent experiments, neutrophils from a healthy donor were exposed to sera of patients with SCD in the presence or absence of DFO or apoTf. NET formation was detected as outlined in (B) and the densities of released DNA were determined after the indicated treatments. Levels of circulating labile iron were measured as indicated in the figure. (E) Neutrophils from a healthy donor were challenged with sickled RBCs in the presence or absence of an anti-C5 blocking monoclonal antibody (80 μg/ml). Release of extracellular DNA (green in these images) was followed over time with live cell imaging over 3 hours. Depicted are images after 3 hours of incubation. Scale bar, 50 μm.

Figure 1.

Aims: To verify the potential therapeutic use of Hpx administration to block NET formation and the occurrence of VOC in human SCD, we aimed to deter-

mine whether *ex vivo* Hpx addition to human SCD sera would prevent NET formation.
Methods: Patient serum and plasma samples were obtained from 32 incidents of VOC in 24 adult SCD patients, with informed consent. Moreover, steady state samples were obtained at least 4 weeks after discharge from the hospital. Patients having had a blood transfusion in the 3 months prior to admission were excluded. NET formation by human neutrophils from healthy donors was studied using confocal fluorescence microscopy and staining for extracellular DNA with the cell nonpermeable dye Sytox Green. The presence of extracellular DNA that stains positive for citrullinated histone H3 confirmed the formation of NETs (Figure 1A).
Results: Indeed, we found that hemin (ferriprotoporphyrin IX) activated neutrophils to generate reactive oxygen species and release NETs, which was prevented by addition of plasma-derived Hpx. Moreover, exposure of neutrophils to sera from patients with SCD promoted NET formation, which was significantly enhanced during VOC. However, we observed that circulating free heme levels were elevated in SCD patient serum irrespective of disease state, and serum concentrations of Hpx were reduced in both VOC and steady state compared to healthy donor serum. Strikingly, addition of Hpx in supraphysiological concentrations failed to prevent the formation of NETs in all SCD sera tested. We and others (Chen *et al. Blood* 2014) have found that, in contrast to hemin, protoporphyrin IX does not trigger NET formation, revealing that the iron atom is required for the release of NETs. This observation led us to investigate whether free iron may directly induce NET formation. When neutrophils were exposed to Fe-NTA or serum from a thalassemia patient with iron overload, NETs were formed. Scavenging of free iron by addition of the iron-chelator deferoxamine or the specific iron-binding protein apotransferrin prevented NET release (Figure 1B). Moreover, we found that sequestration of free iron prevented NET formation induced by a subset (6 out of 11 tested), but not all, sera of patients with VOC (Figure 1C and D). In addition, sickled red blood cells (RBCs) are known to bind to neutrophils in vitro. Here, we found that neutrophils released NETs in response to sickled RBCs, even in the presence of Hpx. By contrast, blocking of complement C5 activation completely prevented the formation of NETs when neutrophils were exposed to sickled RBCs (Figure 1E).
Summary/Conclusions: In summary, we observed that sequestration of free iron with the iron-chelator deferoxamine or the iron-binding protein apotransferrin was effective in more than half of the SCD patient sera, while the binding of heme to Hpx did not prevent NET release in human SCD patient sera. Therefore, we propose that targeting free iron with these iron binding compounds may be explored therapeutically to prevent or treat VOC development in SCD. Finally, complement activation in the presence of sickled RBCs activates neutrophils to release NETs, which may also contribute to VOC and SCD pathogenesis. Therefore, anti-C5 IgG may represent an alternative therapeutic strategy to prevent VOC in SCD.

New drugs for rescue in relapsed/refractory multiple myeloma

(ABR), Redwood City, United States, [18]University of Tübingen, Tübingen, Germany

Background: Elotuzumab is an immunostimulatory monoclonal antibody that targets SLAMF7, a glycoprotein highly expressed on multiple myeloma (MM) cells and natural killer cells. Elotuzumab exerts a dual effect, directly activating natural killer cells and mediating MM cell death via antibody-dependent cell-mediated cytotoxicity. In a 3-year follow-up of ELOQUENT-2 (NCT01239797), elotuzumab plus lenalidomide/dexamethasone (ELd) demonstrated a sustained 27% reduction in the risk of disease progression/death and an overall survival (OS) trend towards benefit compared with lenalidomide/dexamethasone (Ld) alone in patients with relapsed/refractory (RR) MM (Dimopoulos et al, ASH 2015).
Aims: To evaluate the long-term efficacy and safety of ELd following extended 4-year follow-up (median 46 months).
Methods: RRMM patients with 1-3 prior lines of therapy randomized 1:1 received ELd or Ld in 28-day cycles until disease progression/unacceptable toxicity or consent withdrawal. Co-primary endpoints were progression-free survival (PFS) and overall response rate (ORR); OS was a secondary endpoint (analysis not prespecified for this data cut) and safety an exploratory endpoint. Written informed consent was obtained for all patients.

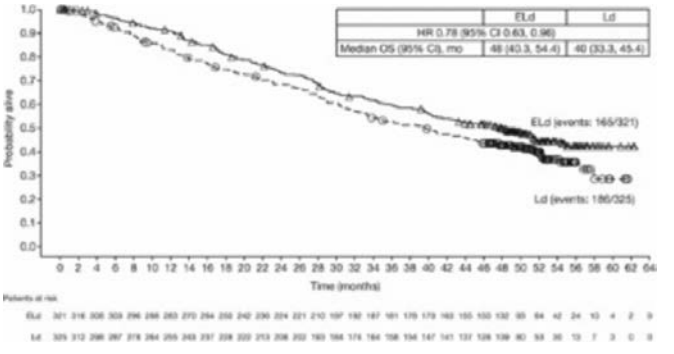

Figure 1. OS Kaplan-Meyer Curve (all randomized patients).

Results: In total, 646 RRMM patients were randomized: 321 to ELd and 325 to Ld. At 4-year follow-up (data cut-off: Oct 18, 2016), nearly twice as many patients remained on ELd therapy *vs* Ld (17% *vs* 9%). With the extended follow-up, ELd demonstrated a sustained relative improvement of 50% in PFS rates *vs* Ld (21% *vs* 14%) and maintained reduction in the risk of progression/death of 29% for ELd *vs* Ld (all randomized patients: HR 0.71; 95% CI 0.59, 0.86). Patients with ≥very good partial response (VGPR) (ELd 112 [35%] *vs* Ld 95 [29%]) had the greatest reduction (35%) in risk of progression/death (HR 0.65; 95% CI 0.46, 0.94). ORR was greater with ELd *vs* Ld (79% *vs* 66%) and the duration of response benefit was maintained over time (HR 0.77; 95% CI 0.62, 0.95). Early separation of the Kaplan–Meier survival curves, which remained consistently separated over time, supports a sustained OS benefit in favor of ELd *vs* Ld (Figure). Grade 3-4 adverse events (AEs) in ≥5% of patients were generally comparable between ELd and Ld arms-vascular diseases (10% *vs* 8%; mostly venous-related), second primary malignancies (SPMs; 9% *vs* 6%) and cardiac disorders (5% *vs* 8%); the exception was a

slightly higher incidence of infection with ELd (33% *vs* 26%). Overall rate (any grade) of infection (84% *vs* 75%) and SPMs (17% *vs* 11%) was also higher for ELd *vs* Ld. However, exposure to ELd was longer than to Ld (median [Q1, Q3] treatment cycles: 19 [9, 42] *vs* 14 [6, 25]). Disease progression and infection were major causes of mortality in both arms; however, fewer deaths were reported with ELd *vs* Ld (165 *vs* 186).
Summary/Conclusions: At 4 years, ELd has the longest median follow-up of an immuno-oncology agent in MM. The data continue to show that adding elotuzumab to Ld results in durable long-term responses, clinically relevant improvement in PFS, sustained reduction in risk of progression/death, and a survival trend in favor of ELd. Overall, these data continue to support the durable efficacy of ELd. Updated safety and tolerability, including rate of SPMs, was consistent with previous findings despite longer exposure, with minimal incremental AEs compared with Ld therapy.

Background: Isatuximab (ISA) is an anti-CD38 monoclonal antibody, which kills tumor cells via multiple mechanisms. Here, we report preliminary data from the dose-escalation cohorts, and the first 3 patients (pts) of the expansion cohort, of a Phase 1b study of ISA plus Pom/Dex in pts with RRMM (NCT02283775).
Aims: To evaluate combination therapy with ISA plus Pom/Dex in pts with RRMM.
Methods: Pts with RRMM (≥2 prior MM therapies, including lenalidomide and a proteasome inhibitor) were sequentially enrolled to ISA 5, 10, or 20mg/kg (4 weekly doses, then every 2 wks until disease progression or intolerable toxicity) with Pom 4mg (Days 1–21) and Dex 40mg (Days 1, 8, 15, and 22; 20mg if ≥75 yrs old), in 28-day cycles. An expansion cohort was initiated at ISA 10mg/kg (plus Pom/Dex) based on preliminary safety, efficacy, and PK data. Primary objective: determine maximum tolerated dose (MTD). All patients were required to provide informed consent.
Results: 26 pts were analyzed (5mg/kg [n=8]; 10mg/kg [n=12]; 20mg/kg [n=6]), median age 65 (42-80) yrs. Median 4.0 (2-11) prior treatment regimens, with 20 (77%) pts refractory to prior immunomodulatory drug therapy. At data cutoff (Nov 8, 2016), median duration of ISA treatment was 19.0 wks and 16 pts remained on treatment. 2 pts at 10mg/kg discontinued therapy due to adverse events (AEs) (grade [Gr] 5 perforated bowel; Gr 3 infusion-associated reaction [IAR]). Dose-limiting toxicities reported in 1 pt at each dose level (Gr 4 neutropenia; Gr 4 neutropenic infection; Gr 3 confusional state), and MTD has not been reached. Most common TEAEs, besides IARs, were fatigue (62%), diarrhea (35%), and dyspnea (31%). Most frequent Gr 3/4 hematologic abnormality (laboratory assessment) was neutropenia (Gr 3, 40%; Gr 4, 52%). Gr 3/4 thrombocytopenia was reported in 8 (32%) pts (Gr 3, 16%; Gr 4, 16%). IARs occurred in 12 (46%) pts (Gr ≥3 in 1 pt); only with 1st infusion in 9/12 pts. 16 (62%) pts achieved at least PR (5, 8, and 3 pts at 5, 10, and 20mg/kg), including 1 CR, 8 VGPR, and 7 PR. Clinical benefit rate (≥MR) was 73%. Median time to 1st response, 4.2 wks; median duration of response, 25.6wks. The PK parameters of ISA were not affected by co-administration with Pom/Dex.
Summary/Conclusions: The combination of ISA and Pom/Dex was manageable and clinically active in heavily pretreated RRMM. A Phase III trial of this combination is ongoing.

S458

OVERALL SURVIVAL OF PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA TREATED WITH CARFILZOMIB AND DEXAMETHASONE *VERSUS* BORTEZOMIB AND DEXAMETHASONE IN THE RANDOMIZED PHASE 3 ENDEAVOR TRIAL

M. Dimopoulos[1,*], H. Goldschmidt[2], R. Niesvizky[3], D. Joshua[4], W.-J. Chng[5], A. Oriol[6], R. Orlowski[7], S. Feng[8], A. Kimball[8], P. Moreau[9]
[1]School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, [2]Heidelberg Medical University, Heidelberg, Germany, [3]Weill Cornell Medical College/New York Presbyterian Hospital, New York, United States, [4]Royal Prince Alfred Hospital, Camperdown, Australia, [5]National University Cancer Institute, National University Health System, Cancer Science Institute, and National University of Singapore, Singapore, [6]Institut Català d'Oncologia, Institut Josep Carreras, Hospital Germans Trias i Pujol, Barcelona, Spain, [7]The University of Texas MD Anderson Cancer Center, Houston, United States, [8]Amgen Inc., Thousand Oaks, United States, [9]University of Nantes, Nantes, France

Background: In a phase 3 head-to-head comparison of two proteasome inhibitors (PIs) in patients with relapsed or refractory multiple myeloma (RRMM), ENDEAVOR, progression-free survival (PFS) was shown to be significantly longer with carfilzomib and dexamethasone (Kd) than with bortezomib and dexamethasone (Vd) (median 18.7 months *vs* 9.4 months, hazard ratio [HR], 0.53; 95% confidence interval [CI], 0.44-0.65; *P*<0.0001; Dimopoulos MA *et al. Lancet Oncol*. 2016;17:27-38).
Aims: Results from a planned second interim overall survival (OS) analysis of ENDEAVOR are presented here.
Methods: Patients who had RRMM and had received 1–3 prior lines of therapy were randomized in a 1:1 ratio to receive Kd or Vd. In the Kd arm, carfilzomib was given on days 1, 2, 8, 9, 15, and 16 (20mg/m^2 on days 1, 2 of cycle 1; 56mg/m^2 thereafter) and dexamethasone 20mg was given on days 1, 2, 8, 9, 15, 16, 22, and 23 of 28-day cycles. In the Vd arm, bortezomib (1.3mg/m^2) was given intravenously or subcutaneously on days 1, 4, 8, and 11 and dexamethasone 20mg was given on days 1, 2, 4, 5, 8, 9, 11, and 12 of 21-day cycles. Patients were treated until progression or withdrawal of consent. OS was compared between treatment arms using a stratified log-rank test.
Results: The median treatment duration was 48 weeks for carfilzomib (N=464) and 27 weeks for bortezomib (N=465), with a median follow up of 38 months for Kd and 37 months for Vd. The median OS (95% CI) was 47.6 (42.5-NE) months in the Kd arm and 40.0 (32.6-42.3) months in the Vd arm, and all-cause mortality was significantly reduced with Kd *vs* Vd (HR, 0.791; 95% CI, 0.648-0.964; 1-sided *p*=0.0100). The overall survival benefit was consistent regardless of prior bortezomib therapy (HR 0.75 for Kd *vs* Vd, no prior bortezomib; HR 0.84 for Kd *vs* Vd, prior bortezomib) and across all age groups (HR, 0.85 <65 yo; 0.71, 65-74 yo; 0.84, ≥75 yo), baseline ECOG performance status groups (HR, 0.81, ECOG 0; 0.80, ECOG 1; 0.50, ECOG 2), cytogenetic risk groups (HR, 0.83, high risk; 0.85, standard risk), and number of prior lines of therapy (HR, 0.83, 1 prior line; 0.76, 2-3 prior lines). The most frequent any-grade adverse events in the Kd arm were (Kd *vs* Vd) anemia (42.5% *vs* 28.3%), diarrhea (36.3% *vs* 40.6%), pyrexia (32.4% *vs* 15.4%), dyspnea (32.2% *vs* 13.6%), fatigue (32.2% *vs* 30.7%), and hypertension (32.2% *vs* 9.9%). Grade 3 or higher adverse events were experienced by 81.4% of patients in the Kd arm and 71.1% of patients in the Vd arm.
Summary/Conclusions: ENDEAVOR was the first randomized phase 3 trial to directly compare two different PIs in RRMM. Patients who received Kd had significantly longer OS compared with patients who received Vd. Safety results were comparable with those previously reported in the PFS interim analysis for ENDEAVOR.

S459

EFFICACY AND SAFETY OF DARATUMUMAB, BORTEZOMIB AND DEXAMETHASONE (DVD) *VERSUS* BORTEZOMIB AND DEXAMETHASONE (VD) IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA (RRMM): UPDATED ANALYSIS OF CASTOR

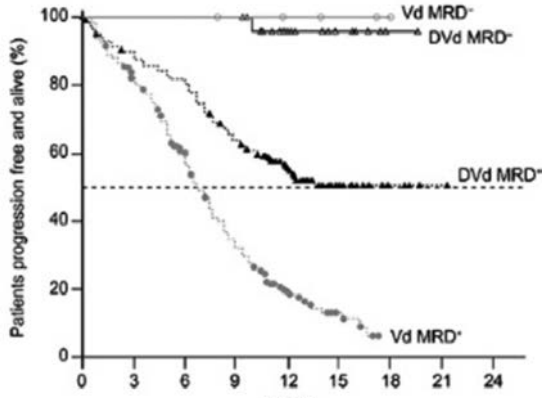
Background: Daratumumab is a human monoclonal antibody targeting CD38 that induces deep and durable responses with significant clinical benefit and is well tolerated as monotherapy and in combination with established standard-of-care regimens in patients with RRMM.
Aims: To provide updated efficacy and safety data from CASTOR, a multicenter, phase 3, randomized, active-controlled study of DVd *vs* Vd in RRMM.
Methods: Eligible patients with ≥1 prior line of therapy were randomly assigned to 8 cycles (every 3 weeks) of Vd (1.3mg/m^2 SC bortezomib on Days 1, 4, 8,

and 11; 20mg PO/IV dexamethasone on Days 1-2, 4-5, 8-9, and 11-12) with or without daratumumab (16mg/kg IV once weekly in Cycles 1-3, every 3 weeks for Cycles 4-8, then every 4 weeks until progression). Patients who were refractory to bortezomib were excluded. Progression-free survival (PFS) was the primary endpoint. Minimal residual disease (MRD) was assessed at suspected complete response (CR) and at 6 and 12 months after first dose at 3 sensitivity thresholds (10^{-4}, 10^{-5}, and 10^{-6}) using the ClonoSEQ™ next-generation sequencing (NGS)-based assay (Adaptive Biotechnologies, Seattle, WA).

Results: A total of 498 patients were randomized with median (range) age of 64 (30-88) years. Patients received a median (range) of 2 (1-10) prior lines of therapy; 66% of patients previously received bortezomib, and 21% were refractory to lenalidomide in their last prior line of therapy. After median follow-up of 13.0 months, DVd significantly prolonged PFS compared with Vd alone (median: not reached *vs* 7.1 months; hazard ratio [HR], 0.33; 95% confidence interval [CI], 0.26-0.43; *P*<0.0001). Twelve-month PFS rates were 60% *versus* 22%, respectively. Significant PFS benefit was observed with DVd over Vd regardless of the number of prior lines of therapy, although the greatest benefit was seen in patients with 1 prior line of therapy (median: not reached *vs* 7.9 months; HR, 0.22; 95% CI, 0.14-0.34; *P*<0.0001). Overall response rate (ORR; 84% *vs* 63%) and rates of very good partial response (VGPR) or better (62% *vs* 29%) and CR or better (26% *vs* 10%) continued to be significantly higher with DVd compared with Vd (*P*<0.0001 for all). MRD-negative rates were more than 4 times higher at all 3 sensitivity thresholds with DVd *versus* Vd: 18.3% *versus* 3.6% at 10^{-4}(*P*<0.0001), 10.4% *versus* 2.4% at 10^{-5} (*P*<0.01), and 4.4% *versus* 0.8% at 10^{-6} (*P*<0.01). MRD-negative patients had prolonged PFS compared with MRD-positive patients at 10^{-5}sensitivity threshold (**Figure**). At the clinical cut-off date, 37 (15%) deaths in the DVd group and 58 (24%) in the Vd group have been observed (HR, 0.63; 95% CI, 0.42-0.96), and follow up is ongoing. Thrombocytopenia was the most common grade 3 or 4 treatment-emergent adverse event (45% with DVd *vs* 33% with Vd). No new safety signals were reported after median treatment duration of 11 months with daratumumab. Updated efficacy and safety data with longer follow up will be presented at the meeting.



No. at risk									
Vd MRD negative	6	6	6	5	3	2	0	0	0
DVd MRD negative	26	26	26	26	15	7	1	0	0
Vd MRD positive	241	176	123	68	20	7	0	0	0
DVd MRD positive	225	189	172	134	76	26	4	1	0

Figure 1.

Summary/Conclusions: DVd is superior to Vd in terms of PFS, ORR, depth of response, and MRD-negative rates, with no new safety signals reported. These updated data further support the use of DVd as a standard of care in RRMM, with the greatest benefit observed in patients with 1 prior line of therapy.

Background: Venetoclax (VEN) is a potent, selective, orally bioavailable small-molecular inhibitor of BCL-2. When combined, VEN can enhance the activity of bortezomib in multiple myeloma (MM) cell lines and xenograft models.

Aims: The objectives of the study are to evaluate safety and preliminary efficacy of VEN with bortezomib and dexamethasone in relapsed/refractory (RR) MM.

Methods: Phase 1b study of patients (pts) with R/R MM who received daily VEN (50-1200mg for dose escalation cohorts; 800mg in safety expansion) with standard bortezomib (1.3mg/m^2 SC) and dexamethasone (20mg PO).

Results: As of 19Aug2016, 66 pts were enrolled. Median age was 64 years; 9 (14%) pts had t(11;14), 5 (8%) had t(4;14), 15 (23%) had del(17p), and 30 (45%) had del(13q) abnormalities. Median number of prior therapies was 3 (range: 1-13), with 39% of pts refractory to prior bortezomib, 14% to carfilzomib, 53% to lenalidomide, and 21% to pomalidomide. Median time on study was 5.9 months (range: 0.3–29.8). Forty-six (70%) pts discontinued, with 36 due to disease progression (PD). Common AEs in ≥30% of pts were diarrhea (46%), constipation (41%), thrombocytopenia (39%), nausea (38%), peripheral neuropathy (33%), and insomnia (32%). Common grade 3/4 AEs in ≥10% of pts were thrombocytopenia (29%), anemia (15%) and neutropenia (14%). Serious AEs in ≥2 pts were febrile neutropenia, thrombocytopenia, cardiac failure, pyrexia, influenza, lower respiratory tract infection, pneumonia, sepsis, acute kidney injury, respiratory failure, embolism, and hypotension. Dose-limiting toxicities were grade 3 cardiac failure in the 300mg cohort (possibly related to dexamethasone) and grade 3 thrombocytopenia during the first cycle in the safety expansion. No events of laboratory or clinical TLS were reported. Four deaths were due to PD and 1 due to respiratory syncytial virus infection. Overall response rate (ORR) for all pts was 67% (44/66); 28 (42%) pts achieved very good partial response (VGPR) or better (3 stringent complete response [sCR], 10 CR, 15 VGPR). Pts non-refractory to prior proteasome inhibitors (PI) or immunomodulatory drugs (IMiDs) had higher ORR than refractory pts (PI, 92% *vs* 32%; IMiDs, 82% *vs* 57%). Among pts refractory to any 2 or more (n=15), 3 or more (n=7), or all 4 (n=4) prior therapies (bortezomib, carfilzomib, lenalidomide, pomalidomide), ORR was 40%, 43%, and 25%, respectively. Median time to progression (~10 *vs* 3 months) and duration of response (~10 *vs* 7 months) were longer for pts not refractory to any of these therapies *versus* refractory pts. ORR for pts with or without cytogenetic abnormalities, respectively, was as follows: 78% *vs* 65% for t(11;14), 60% *vs* 67% for t(4;14), 47% *vs* 73% for del(17p), and 63% *vs* 69% for del(13q).

Summary/Conclusions: VEN combined with bortezomib and dexamethasone has an acceptable safety profile with promising anti-myeloma activity, and the highest response rates were observed in R/R MM pts who were not refractory to PI or IMiDs. These data support the ongoing phase 3 trial with this regimen in R/R MM.

Improving prognostication and front-line therapy in chronic lymphocytic leukemia

S461

CYTOGENETIC COMPLEXITY IN CHRONIC LYMPHOCYTIC LEUKEMIA: DEFINITIONS, ASSOCIATIONS WITH OTHER BIOMARKERS AND CLINICAL IMPACT; A RETROSPECTIVE STUDY ON BEHALF OF ERIC

Background: Recent evidence suggests that complex karyotype (CK) identified by chromosome banding analysis (CBA) may be a relevant biomarker for treatment decisions in CLL, especially regarding the response to signaling inhibitors. However, many challenges towards routine clinical application of CBA still need to be overcome.
Aims: Reappraisal of definitions for CK in CLL and systematic investigation of clinicobiological associations and prognostic impact.
Methods: 3580 CLL and monoclonal B-cell lymphocytosis (MBL) patients (CLL=3322, 93% and MBL=258, 7%, respectively) were analysed with CpG-oligodeoxynucleotides/interleukin 2 (CPG/IL2, n=379, 11%), phorbol-12-myristate-13-acetate (TPA, n=1846, 52%) or both (n=1355, 37%). CBA was mostly performed within the first year from diagnosis and before treatment administration (79% and 88%, respectively). Main features of the studied cohort: median age: 65.6 years/ males: 2252 (63%)/ Binet A/B/C: 2356/357/258 (79%/12%/9%: MBL and Binet A were grouped together)/ IG-unmutated CLL (U-CLL): 829/2051 (40%)/del(13q), 1769/3271 (54%)/ trisomy 12, 507/3260, 16%/ del(11q): 377/3256 (12%)/ *TP53* abnormality (*TP53*abn *i.e.* del(17p) and/or *TP53* mutations): 299/3308 (12%).
Results: Following the current definition for CK *i.e.* ≥3 structural and/or numerical aberrations, 381/3580 cases (11%) displayed CK, with no difference in the detection rate between different cell stimulation protocols. CK was significantly associated ($p<0.05$) with male gender, advanced clinical stage (Binet B/C), U-CLL, del(13q), +12, del(11q) and *TP53*abn. On univariate analysis, CK was associated with inferior OS (median: 11.5 years); CK remained significant also on multivariate analysis along with older age, Binet B/C stage, U-CLL and *TP53*abn. Considering earlier evidence in smaller series that CLL cases with ≥3 structural and/or numerical cytogenetic aberrations are not equivalent, we assessed the relevance of other numerical cut-offs for CK, while also investigating the impact of the type of aberrations (i.e. structural *versus* numerical). CK cases were stratified into those with 3 ('low-CK', n=200, 52%), 4 ('intermediate-CK', n=82, 22%) and ≥5 ('high-CK', n=99, 26%) aberrations. High-CK cases differed significantly ($p<0.05$) from the other two subgroups, being enriched for U-CLL and *TP53*abn (79% and 57%, respectively). The median OS was 5.1 years for the high-CK *vs* not reached for the low- and intermediate-CK groups ($p<0.0001$). We also identified 46 cases (12% of those with ≥3 aberrations) who carried +12,+19 plus other numerical and/or structural abnormalities and displayed extremely indolent clinical course (median OS not yet reached and only 4 deaths at a median follow-up of 5.2 years). When high-CK was assessed as an independent parameter, it was correlated with inferior OS in the univariate analysis, retaining significance also in the multivariate analysis ($p=0.012$) independently of the remaining parameters, including clinical stage, U-CLL and *TP53* status. In contrast, low/intermediate-CK had no impact on OS, not even in univariate analysis ($p=0.57$).
Summary/Conclusions: CK defined by the presence of ≥3 numerical and/or structural abnormalities should not be axiomatically considered unfavorable in CLL, representing a heterogeneous group with variable clinical behavior. High-CK with ≥5 chromosomal aberrations emerges as prognostically adverse, independently of clinical stage, IG somatic hypermutation and *TP53* status. Prospective clinical validation is warranted before finally incorporating high-CK in risk stratification in CLL.

S462

IS FCR THE TREATMENT OF CHOICE FOR IGHV MUTATED CLL WITHOUT POOR FISH CYTOGENETICS?

C. Cuéllar-García[1,*], M. Mattsson[2], P. Baliakas[3], L. Scarfo[4], E. Puy Vicente[5], P. Ghia[6], R. Rosenquist[7], C. Moreno[1]
[1]Department of Hematology, Hospital Santa Creu i Sant Pau, Barcelona, Spain, [2]Hematology, Uppsala University Hospital, [3]Department of Immunology, Genetics and Pathology, Science for Life Laboratory, Uppsala, Sweden, [4]IRCCS Istituto Scientifico San Raffaele, Milano, Italy, [5]Hematology, Hospital Santa Creu i Sant Pau, Barcelona, Spain, [6]Università Vita-Salute San Raffaele, IRCCS Istituto Scientifico San Raffaele, Milano, Italy, [7]Science for Life Laboratory, Uppsala University Hospital, Uppsala, Sweden

Background: Chemoimmunotherapy (CIT) is the standard treatment for young and fit treatment-naïve patients with CLL. The median progression-free-survival (PFS) in patients treated with CIT is about 5-6 years and the overall survival (OS) is increased by 5-10% compared to those treated with chemotherapy only. Patients with mutated IGHV genes (M-CLL*)* and no unfavorable cytogenetic alterations (i.e. del(17p)/*TP53* mutation, and del(11q)) have a better outcome than those with unmutated IGHV genes (U-CLL) and/or poor FISH cytogenetics and show a plateau in survival curves, suggesting that a fraction of these patients may have a survival similar to general population. Nevertheless, the possibility that some M-CLL patients without unfavorable cytogenetics are overtreated is of concern because of the treatment toxicity related to CIT, particularly FCR.
Aims: The aim of this study was to analyse the outcome of M-CLL patients with no unfavorable cytogenetics CLL according to the type of therapy.
Methods: We analysed 816 CLL patients from Sant Pau Hospital, Barcelona, Spain; Uppsala Universitary Hospital, Sweden and IRCCS San Raffaele Scientific University, Milan, Italy for whom IGHV mutational status was available. Endpoints were OS and TFS.

Table 1.

Clinical and biological characteristics at diagnosis

	m-IGHV (n=488)	*u-IGHV (n=328)*
Median Age	63y (30-88)	63y (27-89)
Male/Female	284/204	181/147
Clinical Stages		
Binet A/B/C	412/32/16	222/62/20
RAI 0/I-II/III-IV	329/105/26	162/14/26
FISH cytogenetics		
del 13q	212/432	92/298
trisomy 12	25/433	56/298
del 11q	8/426	11/293
del 17p	18/433	42/298

Results: 488 patients had mutated IGHV genes (400 without unfavorable FISH cytogenetics; 26 had either del(11q) and/or del(17p), and in 62 cases FISH was not available) and 328 patients carried unmutated IGHV genes. The main clinical and biological characteristics at diagnosis are shown in Table 1. OS at 5 and 10 years was 93% (CI, 95-91) and 81% (CI, 85-77) for M-CLL cases and 78% (CI, 83-73) and 46% (CI, 52-39) for U-CLL cases ($p<0.05$). TFS at 5 and 10 years was 73% (CI, 77-69) and 61% (CI, 66-56) and 28% (CI, 33-23) and 10% (CI, 14-6) for M-CLL and U-CLL, respectively ($p<0.05$). After a median follow-up of 8 years (range, 1-26), 424 patients [161 M-CLL (136 without poor-prognostic FISH cytogenetics, 13 with either del(11q) and/or del(17p) and 12 cases in whom FISH information was not available) and 263 U-CLL] required therapy. Front-line treatment consisted of purine analogues (PA)-based therapy (n=83), alkylating agents (n=212), anti-CD20 moAbs with PA or bendamustine (n=75), anti-CD20 moAbs with alkylating agents (n=21), BCR-signal inhibitors or BCL2 antiapoptotic agents (n=9), others (n=23), and unknown (n=1). The

median duration of response to first therapy was 42 months (range, 33-52) in M-CLL cases *vs* 24 months (range, 18-30) in U-CLL patients (p<0.001). 282 patients received a second line of therapy: PA-based therapy (n=95), alkylating agents (n=82), anti-CD20 moAbs with PA or bendamustine (n=33), anti-CD20 moAbs with alkylating agents (n=16), BCR-signal inhibitors or BCL2 antiapoptotic agents (n=12), others (n=39), and unknown (n=5). In 481 of 816 patients in whom detailed information on treatment regimens beyond second-line was available, 99 patients received a third-line treatment including PA-based therapy (n=15), alkylating regimens (n=20), anti-CD20 MoAbs with PA or bendamustine (n=15), anti-CD20 moAbs with alkylating agents (n=8), BCR or BCL2 inhibitors (n=11), others (n=28) and unknown (n=2); 49 patients received four or more lines of therapy. In M-CLL patients without poor FISH cytogenetics (n=136) the type of therapy did not impact patients´ outcome. Thus, the median survival was not reached in patients treated with CIT as first-line (i.e FCR, BR) as compared to 202 months in those not having received CIT (p=0.317). In contrast, in U-CLL patients the OS was highly dependent on the type of therapy. In detail, U-CLL patients who received anti-CD20 MoAbs with PA or bendamustine either as first line or subsequent lines (60 of 120 patients) showed significantly longer survival than those who did not receive these therapeutic regimens (median survival: 173 *vs* 103 months, p=0.001). On the contrary, in M-CLL cases no differences in survival were observed in those receiving anti-CD20 MoAbs with PA or bendamustine *vs* who did not (p=0.558).

Summary/Conclusions: This retrospective study suggests that OS of CLL patients with mutated IGHV genes and no unfavorable FISH cytogenetics do not depend on the type of therapy. This has important clinical implications and provides background for randomized studies aimed at identifying the optimal treatment strategy for this group of patients.

S463

IBRUTINIB, FLUDARABINE, CYCLOPHOSPHAMIDE, AND OBINUTUZUMAB (GA101) (IFCG) FOR PREVIOUSLY UNTREATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) WITH MUTATED IGHV AND NON-DEL(17P)

N. Jain[1,*], P. Thompson[1], J. Burger[1], G. Borthakur[1], P. Bose[1], Z. Estrov[1], A. Ferrajoli[1], V. Gandhi[2], W. Plunkett[2], W. Lopez[1], H. Kantarjian[1], S. O'Brien[3], M. Keating[1], W. Wierda[1]
[1]Leukemia, [2]Experimental Therapeutics, MD Anderson Cancer Center, Houston, [3]Hematology-Oncology, UC Irvine, Irvine, United States

Background: Patients with mutated *IGHV* (*IGHV*-M) have favorable long-term outcomes (10-year PFS of >60%) after receiving first-line FCR.
Aims: To develop an FC-based chemoimmunotherapy regimen of finite duration that included ibrutinib and obinutuzumab. The intent was to limit FC to 3 courses, potentially reducing short- and long-term toxicity, while maintaining efficacy through the addition of ibrutinib and a more potent antibody (obinutuzumab).
Methods: We designed an investigator-initiated phase II trial with ibrutinib, fludarabine, cyclophosphamide, and obinutuzumab (iFCG) for previously untreated pts with *IGHV*-M CLL (NCT02629809). The intent was to limit FC to 3 courses, potentially reducing short- and long-term toxicity, while maintaining efficacy through addition of ibrutinib and obinutuzumab. Key eligibility included age ≥18, *IGHV*-M, no del17p. Pts received 3 courses of iFCG. G-CSF was not mandated. Primary endpoint: CR/CRi with bone marrow (BM) MRD-neg (4-color flow-cytometry) after 3 courses of iFCG. Pts meeting primary endpoint received ibrutinib with obinutuzumab (iG) for C3-6, then ibrutinib C7-12. Pts not achieving primary endpoint received iG (C4-12). All pts who are MRD neg at 1 year will stop all therapy, including ibrutinib. Pts MRD+ at 1 year may continue ibrutinib. Historic C3 BM MRD-neg with FCR in *IGHV*-M 26% (Strati, Blood 2014). Target BM MRD-neg after iFCG x3 is 45%. Sample size 45.
Results: Since activation (April 2016), 26 patients were consented; 23 initiated treatment. We report data on these 23 patients. This is the first report of this trial. Median age is 59 years (range, 25-71); there were 18 men. Prognostic markers included [FISH: del13q (n=17), negative (n=3); trisomy 12 (n=3); CD38+ (n=7); ZAP70+ (n=6/21 evaluated)]. By trial design, all patients had *IGHV*-M. Median B2M was 2.6 (range, 1.4-8.1). Median pretreatment WBC count was 81.1 K/µL (range, 3.1-224), platelet count 120 K/µL (range, 62-292), hemoglobin 12.4 g/dL (range, 9.1-15.6). Eighteen patients have completed 3 courses of iFCG and had initial response assessment (the remaining 5 patients have not yet completed 3 courses of treatment). All 18 patients achieved a clinical response; 14/18 (78%) achieved MRD-negative remission in the marrow at 3 month (Table 1) and 16/18 (89%) achieved MRD-negative remission as their overall best response. Overall, 7/18 achieved CR/CRi with MRD-negative status in bone marrow at 3 months. All patients with PR had bulky adenopathy at baseline, and had residual lymphadenopathy ranging from 1.8 to 3.5 cm after 3 courses of iFCG. No patient has progressed, and all but one continue to receive treatment on protocol. Of the 23 pts, 11 pts had G3-4 neutropenia and 5 pts had G3-4 thrombocytopenia. 4 pt had neutropenic fever. 1 pt who achieved MRD-neg CR developed pulmonary MAC infection, and declined further therapy. 1 pt had atrial fibrillation. G3 ALT developed in 3 pts. FC was dose reduced in 10 pts; ibrutinib dose-reduced in 2 pts.

Table 1.

	N=18	Marrow MRD	N=18	Marrow MRD
ORR	18/18 (100)	14/18 (78) neg	18/18 (100)	16/18 (89) neg
CR/CRi	7 (39)	7/7 (100) neg	9 (50)	9/9 (100) neg
PR	11 (61)	7/11 (64) neg	9 (50)	7/9 (78) neg

Summary/Conclusions: iFCG achieves high rate of MRD-neg remission after 3 courses. Pt enrollment continues, and updated results will be presented at the EHA meeting.

S464

BENDAMUSTINE (B), FOLLOWED BY OBINUTUZUMAB (G, GA101) AND VENETOCLAX (A, ABT-199) IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): CLL2-BAG PHASE-II-TRIAL OF THE GERMAN CLL STUDY GROUP (GCLLSG)

P. Cramer[1,*], J. von Tresckow[1], J. Bahlo[1], S. Robrecht[1], O. Al Sawaf[1], P. Langerbeins[1], A. Engelke[1], A.-M. Fink[1], K. Fischer[1], T. Seiler[2], L. Fischer von Weikersthal[3], H. Hebart[4], K.-A. Kreuzer[5], M. Ritgen[6], M. Kneba[6], C.-M. Wendtner[7], S. Stilgenbauer[8], B. Eichhorst[1], M. Hallek[1]
[1]Department I of Internal Medicine and German CLL Study Group, University Hospital Cologne, Cologne, [2]Department III of Internal Medicine, University Hospital Munich, Ludwig-Maximilians University, Campus Großhadern, Munich, [3]Gesundheitszentrum St. Marien, Amberg, [4]Stauferklinikum, Schwäbisch-Gmünd, [5]Department I of Internal Medicine, University Hospital Cologne, Cologne, [6]Department II of Internal Medicine, Campus Kiel, University of Schleswig-Holstein, Kiel, [7]Department of Hematology, Oncology, Immunology, Palliative Care, Infectious Diseases and Tropical Medicine, Klinikum Schwabing, Munich, [8]Department III of Internal Medicine, University Hospital Ulm, Ulm, Germany

Background: Based on the theoretical "sequential triple-T" concept [Hallek M., Blood 2013; 122(23): 3723-34] of a tailored and targeted treatment aiming for total eradication of minimal residual disease (MRD), the GCLLSG designed the CLL2-BAG trial.
Aims: This prospective, open-label, multicenter phase-II trial investigates a sequential treatment with a B debulking, followed by G and A as induction and maintenance therapy in an all-comer population of physically fit and unfit, treatment-naïve (TN) and relapsed/refractory (R/R) CLL pts.
Methods: Pts with an absolute lymphocyte count (ALC) ≥25.000/µl and/or lymph nodes (LN) ≥5cm were to receive 2 cycles of B as debulking (70mg/m^2 d1&2 q28 days), unless contraindicated. In the induction G (1000mg) was administered 3 times in cycle 1 (days 1/2, 8 & 15) and every 4 weeks in cycles 2-6. A was added in cycle 2 with a dose ramp-up (to 400mg daily) over 5 weeks and several safety precautions. In the maintenance therapy, daily intake of A was continued and G administered every 3 months until achievement of a MRD-negative complete response or for up to 24 months. The primary endpoint is the overall response rate (ORR) at the end of induction therapy; secondary endpoints include MRD evaluations, safety and survival parameters. This primary endpoint analysis is based on uncleaned data, the final analysis will be presented at the meeting.

Table 1.

Efficacy (at end of induction treatment)

	all patients	treatment-naive	relapsed/refractory
Response (according to iWCLL guidelines)			
- CR/CRi	6 (9.5%)	3 (8.8%)	3 (10.3%)
- PR	55 (87.3%)	31 (91.2%)	24 (82.8%)
- SD	1 (1.6%)	-	1 (3.4%)
- PD	1 (1.6%)	-	1 (3.4%)
MRD in peripheral blood			
- negative (< 10^{-4})	56 (88.9%)	33 (97.1%)	23 (79.3%)
- intermediate (≥ 10^{-4} and < 10^{-2})	-	-	-
- positive (≥ 10^{-2})	4 (6.3%)	1 (2.9%)	3 (10.3%)
- missing	3 (4.8%)	-	3 (10.3%)
MRD in bone marrow			
- negative (< 10^{-4})	8 (12.7%)	4 (11.8%)	4 (13.8%)
- intermediate (≥ 10^{-4} and < 10^{-2})	-	-	-
- positive (≥ 10^{-2})	-	-	-
- missing	55 (87.3%)	30 (88.2%)	25 (86.2%)

Results: Between May 2015 and January 2016, 66 pts were enrolled. Two R/R pts died of a sepsis and 1 TN pt discontinued due to toxicity during the first induction cycle; these 3 pts with <2 induction cycles were excluded from the analysis as predefined by protocol. 34 pts were treatment-naïve and 29 had R/R CLL (median number of prior therapies: 2, range: 1-8). Median age was 59 (28-77) years, the median CIRS score was 2 (0-14) and 16 pts (25%) had a creatinine clearance of 30-70ml/min. 11 of 59 pts (19%) had a del(17p) and 45 of 61 (74%) had an unmutated IGHV status. Risk categories for TLS at baseline were: low (ALC <25.000/µl & LN <5cm): 9 pts (15%), intermediate (ALC ≥25.000/µl or LN 5-10cm): 35 (58%) and high (ALC ≥25.000/µl & LN 5-10cm or LN >10cm): 16 (27%), 3 missing. 45 pts (71%) received B debulking, 18 (29%) pts immediately started with the induction. 60 pts completed 6 induction cycles with G and A. All TN (100%) and all but two of the R/R pts (93%) respond-

ed (table 1); with an ORR of 97% at the end of induction, the primary endpoint was met. MRD negativity (<10^{-4} by flow cytometry) in peripheral blood (pB) was achieved in 56 pts (89%); MRD assessment from bone marrow was available in 8 pts (4 TN and 4 R/R, among them 4 with a CR and 4 with a PR) and were all negative. As of January 9th2017, 83 serious adverse events (SAEs) were reported in 37 pts, including 69 SAEs (83%) related to study treatment. 66 SAEs (80%) were CTC°3-4 and 1 had a fatal outcome (sepsis in 4th induction cycle). Most SAEs occurred in the R/R cohort (61 SAEs, 74%) and during the induction phase (63 SAEs, 76%). Most common SAEs were infections (27 in 16 pts; including 13 CTC°3-5) and hematological disorders (18 in 10 pts; 10 CTC°3-4), followed by infusion-related reactions (6 in 6 pts), laboratory TLS (5 in 5 pts; 1 during B debulking, 1 in induction cycle 1 with G, 2 in cycle 3 and 1 in cycle 4 with G and A) and ischemic coronary artery disorders (5 in 4 pts). No clinical TLS occured.

Summary/Conclusions: With an ORR of 97% and a MRD negativity rate of 89% in pB at the end of induction phase this sequential treatment of B debulking, followed by G and A was very efficacious in a heterogeneous study population and well tolerated except for 3 fatal septicaemias in R/R pts.

S465

SAFETY RESULTS OF TERMINATED PHASE 2 STUDY OF IDELALISIB PLUS RITUXIMAB IN TREATMENT NAÏVE CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) WITH DEL(17P)

P. Hillmen[1,*], X. Badoux[2], J. Delgado[3], V. Leblond[4], A. Mato[5], M. Simkovic[6], R.L. Dubowy[7], Y. Kim[7], A. Pluta[8], M. Montillo[9]
[1]The Leeds Teaching Hospitals, St. James Institute of Oncology, Leeds, United Kingdom, [2]St. George Hospital, Kogarah, Australia, [3]Hospital Clinic de Barcelona, Barcelona, Spain, [4]Hôpital de la Pitié-Salpétrière, Paris, France, [5]Hospital of the University of Pennsylvania, Philadelphia, United States, [6]University Hospital and Charles University, Faculty of Medicine, Hradec Králové, Czech Republic, [7]Gilead Sciences, Inc., Foster City, United States, [8]Specialistic Hospital, Brzozow, Poland, [9]Niguarda Hospital, Hematology Department, Niguarda Cancer Center, Milano, Italy

Background: Idelalisib (IDELA) is an oral PI3Kδ inhibitor approved in the EU for use with rituximab (R) or ofatumumab in patients (pts) with previously treated CLL or as first-line treatment of CLL with either del(17p) or TP53 mutation in pts unsuitable for other therapies. Prior single arm studies have suggested that front line use of IDELA may be associated with an increased frequency of transaminase elevations compared to relapsed pts.

Aims: To describe: 1) the safety of IDELA plus rituximab in previously untreated CLL pts with del(17p) in this terminated study, and 2) the relation of key AEs and age.

Methods: Treatment-naïve pts with CLL and confirmed del(17p) were treated in a single arm study with R 375mg/m² IV weekly x8 and IDELA 150mg PO BID continuously until disease progression or intolerability. Informed consent was obtained. The study was fully enrolled when terminated early due to infection related safety concerns observed in a pooled analysis of ongoing Ph3 IDELA trials in front/early line therapy; the planned independent efficacy analysis was not performed, but investigator assessment is available.

Results: 102 pts (median age, 66; range, 37-86) were enrolled between Aug 2014 and Jan 2016 and received IDELA for a median (med) duration of 6.4 months (range, 0.7-17.0). The study was terminated in Mar 2016, >8 wks after dosing of the last enrolled pt. 77 pts (75.5%) remained on study at the time of study termination. The reasons for discontinuation from study were death (4.9%), progressive disease (3.9%, 1 fatal), investigator discretion (9.8%), withdrawal of consent (2.9%), other anticancer therapy (2.0%), and lost to follow up (1.0%). The investigator assessed response rate was 79%. 101 pts (99%) had adverse events (AEs); Gr ≥3 occurred in 80.4%, the most frequent Gr ≥3 were ALT increased (27.5%), neutropenia (20.6%), infections (18.6%), and diarrhea (14.7%). Laboratory Gr ≥3 ALT and/or AST elevations were seen in 41.2%, with med time of onset of 8.1 wks (range 4.1-24.1). The med age of pts both with and without Gr ≥3 ALT/AST was 66 years, and the incidence of Gr ≥3 ALT/AST was similar in younger (43.9%, <65yr) and older (39.3%, ≥65yr) pts. Gr ≥3 diarrhea/colitis occurred in 17.1% of pts <65yr and in 14.8% of pts ≥65yr. Dose interruptions due to AEs occurred in 71 pts (70%), most frequently due to transaminase elevations (37.3%), and diarrhea/colitis (15.7%). Discontinuation due to AEs occurred in 27% of pts, most frequently due to ALT/AST elevation (9.8%). Serious adverse events were reported in 46 (45.1%), including pyrexia (10.8%), diarrhea/colitis (11.8%). AEs of special interest included Gr ≥3 infections in 20 pts (19.6%) of whom 5 had CMV and 3 had PJP (none on prophylaxis), Gr ≥3 febrile neutropenia in 5 (4.9%) and any grade pneumonitis in 5 (4.9%). Of the 5 pts with CMV, all were CMV IgG+ at screening and 2 also were IgM+. There were 6 on-study deaths, 3 associated with infection, 2 due to CLL progression and 1 due to heart failure.

Summary/Conclusions: In IDELA plus rituximab treated front-line CLL, the pattern of AEs was similar to that seen in relapsed CLL studies at similar duration of therapy, however the frequency of Gr ≥3 ALT/AST was increased compared to the relapsed setting. There was no significant effect of age on the risk of either ALT/AST elevations or diarrhea/colitis. The occurrence of CMV and PJP infections is consistent with current IDELA labeling and speaks to the potential benefit of risk mitigation through PJP prophylaxis and CMV monitoring during treatment. NCT02044822.

Aggressive Non-Hodgkin lymphoma - Relapsed/refractory

S466

CLINICAL AND BIOLOGIC COVARIATES OF OUTCOMES IN ZUMA-1: A PIVOTAL TRIAL OF AXICABTAGENE CILOLEUCEL (AXI-CEL; KTE-C19) IN PATIENTS WITH REFRACTORY AGGRESSIVE NON-HODGKIN LYMPHOMA (NHL)

F.L. Locke[1], S.S. Neelapu[2], N.L. Bartlett[3], L.J. Lekakis[4], D. Miklos[5], C.A. Jacobson[6], I. Braunschweig[7], O. Oluwole[8], T. Siddiqi[9], Y. Lin[10,*], J. Timmerman[11], P.M. [1]H Lee Moffitt Cancer Center & Research Institute, Tampa, [2]The University of Texas MD Anderson Cancer Center, Houston, [3]Washington University, St. Louis, [4]University of Miami, Miami, [5]Stanford University, Stanford, [6]Dana-Farber Cancer Institute, Boston, [7]Montefiore Medical Center, Bronx, [8]Vanderbilt University Medical Center, Nashville, [9]City of Hope, Duarte, [10]Mayo Clinic, Rochester, [11]University of California at Los Angeles, Los Angeles, [12]University of Rochester School of Medicine, Rochester, [13]Kite Pharma, Santa Monica, United States

Background: Outcomes for pts with refractory aggressive NHL are poor with current therapies (Crump, ASCO 2016). Results from the interim analysis of (n=62) of ZUMA-1, the 1st multicenter trial of an anti-CD19 chimeric antigen receptor (CAR) T cell, axi-cel, in refractory aggressive NHL, showed an objective response rate (ORR) of 79% (complete response [CR] 52%; *Blood* 2016;128:LBA-6). Here we present results from the primary analysis of ZUMA-1.

Aims: Here we present results from the primary analysis of the ZUMA-1 trial.

Methods: Pts received a target dose of 2 × 10^6 anti-CD19 CAR T cells/kg after low- dose conditioning with cyclophosphamide and fludarabine. Eligible pts (≥18 y) had diffuse large B cell lymphoma (DLBCL), primary mediastinal B cell lymphoma (PMBCL) or transformed follicular lymphoma (TFL); an ECOG performance status (PS) 0-1; and refractory disease (progressive or stable disease as best response to last prior therapy, or relapsed ≤12m of autologous stem cell transplant [ASCT]). The primary endpoint for this analysis was ORR in the combined DLBCL, PMBCL, and TFL population. Key secondary endpoints were duration of response (DOR), overall survival (OS), and frequency of adverse events (AEs). The primary analysis was triggered when 92 pts had at least 6m of follow-up

Results: As of January 27, 2017, 111 pts from 22 institutions were enrolled; 101 pts (91%) received axi-cel. Median age was 58 y (range, 23-76), 67% male, 85% stage III-IV, 47% IPI 3-4, 77% refractory to ≥2nd line of therapy, and 21% relapsed ≤12m of ASCT. Axi-cel was successfully manufactured in 110/111 (99%) pts with an average turnaround time from apheresis to the clinical site of 17 d. With an ORR of 82% (n=92; *P*<.0001) the study met the primary endpoint. The ORR in the mITT analysis set of 101 pts was 82% (CR 54%, PR 28%), and was consistent across key covariates including disease subtype, refractory status, stage, and IPI score. At a median follow up of 8.7 m, 44% of pts were in response and 39% were in CR. The median DOR was 8.2m overall and not reached for pts who achieved a CR. Median OS was not reached; 80% of pts remained alive at 6 m. The most common Gr ≥3 treatment-emergent AEs were neutropenia (66%), leukopenia (44%), anemia (43%), febrile neutropenia (31%), and encephalopathy (21%). Gr ≥3 cytokine release syndrome (CRS) and neurologic events (NE) occurred in 13% and 28% of pts, respectively. All CRS and all NE resolved except 1 Gr 1 memory impairment. As previously reported, there were 3 Gr 5 AEs (3%). Peak CAR T levels and AUC post–axi-cel were associated with durable responses. Additionally, this presentation will include an expanded analysis of efficacy outcomes by novel biologic and clinical covariates including key molecular phenotypes and tocilizumab/corticosteroid interventions used for management of adverse events.

Summary/Conclusions: Axi-cel significantly improved ORR in patients with refractory aggressive NHL. The CR rate was 7-fold higher compared to historical controls (Crump, ASCO 2016) and nearly half the patients had an ongoing response. Axi-cel demonstrated significant clinical benefit with a manageable safety profile in pts lacking curative treatment options.

Drs Locke and Neelapu contributed equally to this study

CC-122 IN COMBINATION WITH OBINUTUZUMAB (GA101): PHASE IB STUDY IN RELAPSED OR REFRACTORY PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA, FOLLICULAR LYMPHOMA, OR MARGINAL ZONE LYMPHOMA

J.-M. Michot[1], R. Bouabdallah[2,*], J.K. Doorduijn[3,4], U. Vitolo[5], M.J. Kersten[4,6], A. Chiappella[5], P. L. Zinzani[7], R. Sarmiento[8], S. Mosulen[8], M. Petrarca[9], M. Pourdehnad[9], K. Hege[9], Z. Yang[10], Z. Nikolova[8], V. Ribrag[1]
[1]Institut Gustave Roussy, Villejuif, [2]Institut Paoli-Calmettes, Marseille, France, [3]Erasmus MC Cancer Institute, Rotterdam, [4]On behalf of the LLPC (Lunenburg

Lymphoma Phase I/II Consortium), Amsterdam, Netherlands, [5]Azienda Ospedaliera Universitaria Città della Salute e della Scienza di Torino, Torino, Italy, [6]Academic Medical Center, Amsterdam, Netherlands, [7]Institute of Hematology "Seràgnoli," University of Bologna, Bologna, Italy, [8]Celgene Institute for Translational Research Europe, Seville, Spain, [9]Celgene Corporation, San Francisco, CA, [10]Celgene Corporation, Berkeley Heights, NJ, United States

Background: CC-122 is a cereblon modulating agent that degrades Aiolos and Ikaros, resulting in potent anti-lymphoma and immunomodulatory effects on T- and NK-cell function. Phase I clinical data revealed promising activity of CC-122 against follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL). Preclinical combination of CC-122 with obinutuzumab has shown synergism in FL and additive effects in DLBCL *vs* either single agent (Chiu. ASH 2015), supporting further study of this combination's therapeutic potential.
Aims: The current phase Ib study (EUDRACT 2014-003333-26; NCT02417285) evaluates the safety and efficacy of CC-122 plus obinutuzumab in patients with relapsed or refractory (R/R) B-cell non-Hodgkin lymphoma (NHL).
Methods: Patients at study entry must have R/R CD20+ B-cell NHL after ≥1 prior regimens for FL/marginal zone lymphoma (MZL) and ≥2 regimens and/or ASCT for DLBCL. CC-122 was given orally (5 of 7 d) for 28-d cycles in escalating doses plus a fixed dose of intravenous obinutuzumab 1000mg on d2, 8, 15 of cycle 1 (c1) and d1 of c2-8, upon informed consent. CC-122 was continued until progressive disease (PD) or unacceptable toxicity. CC-122 active ingredient in capsule formulation (AIC) 1, 2, 3, and 4mg and CC-122 formulated capsules (F6) 3 and 4mg were evaluated in separate cohorts. Primary endpoints included safety and tolerability, non-tolerated dose (NTD), and maximum tolerated dose (MTD). Response was assessed using the international Cheson 2007 criteria every 2 cycles to c6, every 3 cycles to c12, and every 6 cycles thereafter.
Results: As of January 12, 2017, 34 R/R B-cell NHL patients with DLBCL (n=18), FL (n=15), or MZL (n=1) were enrolled. At study entry, median age was 60 y (26-81), most patients were male (68%), and Ann Arbor was extended stage III/IV in 76% of patients. Of the 18 DLBCL patients, 8 had transformed FL. Of the 16 FL/MZL patients, 44% relapsed in <12 months after first-line treatment. The median number of prior regimens was 4 (range, 1-11), and 13 (38%) patients had received prior SCT. One patient experienced a dose-limiting toxicity (DLT) of grade 4 neutropenia (CC-122 dose level of AIC 3mg); no dose was yet an NTD. Median CC-122 duration was 22 wks (range, 3-71) equivalent to 6 cycles (range, 1-18). CC-122 dose reduction or temporary interruption occurred in 10 (29%) or 26 (76%) of patients, respectively, primarily due to adverse events (AEs). Most patients (56%) had <1 wk of interruption due to AEs. The most common (≥10%) grade 3/4 treatment-emergent AEs (TEAEs) were neutropenia (50%) and thrombocytopenia (21%). Fifteen patients (44%) had ≥1 serious TEAE, including 2 each of febrile neutropenia (related to CC-122), cytokine release syndrome (related to obinutuzumab), and pneumonia. Three deaths occurred during the study (2 PD; 1 AE-related). Overall response rate (ORR) was 59%, including 26% CR and 32% PR (Table 1). Median time to best response was 57 d, and median duration of response was not yet reached. In evaluable patients, 6-mo progression-free survival (PFS) was 63%.

Table 1.

Table 1. Best responses with CC-122 and obinutuzumab in evaluable patients.

Response Status, n (%)	R/R DLBCL* n=18	R/R FL/MZL n=16	All Patients N=34
ORR	8 (44)	12 (75)	20 (59)
CR	3 (17)	6 (38)	9 (26)
PR	5 (28)	6 (38)	11 (32)
SD	4 (22)	3 (19)	7 (21)
PD	3 (17)	1 (6)	4 (12)

Data cutoff was 10Feb2017. *3 patients were not evaluable for efficacy.

Summary/Conclusions: The combination of CC-122 and obinutuzumab was well tolerated and demonstrates promising response rates and durable remissions in R/R patients with B-cell NHL. CC-122 doses of ≥3mg and obinutuzumab have shown best response rates to date. The study is ongoing to establish the phase II recommended dose.

S468

POLATUZUMAB VEDOTIN PLUS BENDAMUSTINE AND RITUXIMAB OR OBINUTUZUMAB IN RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA OR DIFFUSE LARGE B-CELL LYMPHOMA: UPDATED RESULTS OF A PHASE 1B/2 STUDY

M. Matasar[1,*], A.F. Herrera[2], M. Kamdar[3], A. Mehta[4], S. Assouline[5], I. Fleury[6], T.M. Kim[7], W.S. Kim[8], F. Bosch[9], J. Radford[10], C.R. Flowers[11], L. Bu[12], W.-J. Hong[13], L.H. Sehn[14]
[1]Memorial Sloan Kettering Cancer Center, New York, [2]City of Hope, Duarte, [3]University of Colorado, Denver, [4]Department of Medicine, University of Birmingham, Birmingham, United States, [5]Jewish General Hospital, [6]Department of Hematology, Maisonneuve-Rosemont Hospital and University of Montreal, Montreal, Canada, [7]Seoul National University Hospital, [8]Samsung Medical Center, Seoul, Korea, Republic Of, [9]Hospital Universitari Vall d'Hebron, Barcelona, Spain, [10]Manchester Academic Health Science Centre, The University of Manchester and the Christie NHS Foundation Trust, Manchester, United Kingdom, [11]Winship Cancer Institute of Emory University, Atlanta, United States, [12]Roche, Shanghai, China, [13]Genentech, Inc., South San Francisco, United States, [14]BC Cancer Agency, Vancouver, Canada

Background: Transplant ineligible patients (pts) with relapsed/refractory (R/R) FL or DLBCL have poor outcomes. Polatuzumab vedotin (pola) is an antibody drug conjugate that targets delivery of the microtubule inhibitor MMAE to cells expressing CD79b. Pola + rituximab (R) previously showed promising responses in R/R FL and DLBCL. Adding bendamustine (B) to pola-R and substituting obinutuzumab (G) for R could improve outcomes. We report updated results from the Phase 1b/2 (P1b/2) study evaluating pola + BR or BG in R/R FL and DLBCL and the expansion cohorts evaluating pola + BG in R/R FL and DLBCL (ClinicalTrials.gov NCT02257567).
Aims: The primary aim is to assess safety and tolerability of pola + BR/BG in R/R FL and DLBCL. Secondary aims include assessing safety and efficacy of pola + BG in an expansion cohort.
Methods: All pts provided informed consent to participate in the study and were treated with pola (1.8mg/kg) + B (90mg/m^2) and R (375mg/m^2) or G (1000mg) every 28 days (FL) or 21 days (DLBCL) for 6 cycles. Responses were assessed by modified Lugano 2014 criteria after 3 cycles, end of treatment (tx), and every 6 months for 2 years during follow-up (fu).
Results: As of 14 Nov 2016, 65 pts were enrolled: 24 pts (12 FL, 12 DLBCL) in P1b and 41 pts (20 FL and 21 DLBCL) in P2. In safety evaluable pts, FL pts (N=32) were median age of 63 yr (37-86), 82% ECOG 0-1 and 6% ECOG 2, 44% FLIPI1 3-5, 78% Stage III/IV, 2 (1-7) median lines of prior tx, 38% refractory to last tx, 13% prior transplant (BMT). DLBCL pts (N=32) were median age 66 (30-86), 88% ECOG 0-1 and 13% ECOG 2, 59% IPI 3-5, 75% Stage III/IV, 2 (1-7) median lines of prior tx, 82% refractory to last tx, 3% prior BMT. Among 64 pts who received ≥1 dose, the adverse events (AEs) that occurred in >20% of pts were: fatigue (67%), nausea (54%), diarrhea (54%), vomiting (42%), pyrexia (39%) and constipation (39%). As expected, grade (Gr) 3/4 cytopenias were common: neutropenia (34% FL, 28% DLBCL), thrombcytopenia (16% FL, 13% DLBCL), anemia (6% FL, 9% DLBCL). Tx emergent neuropathy occurred in 19/64 (30%) of pts, with 1 Gr 3 event, and led to pola discontinuation in 1 pt, dose reduction in 2 pts, and interruption in 1 pt. In FL, 75% (24/32) had Gr 3/4 AEs and 41% (13/32) had serious AEs (SAEs). The only SAE occurring in ≥10% was infection (22%). The most common Gr 3/4 non-heme AEs were infection (16%) and hypokalemia (9%). AEs led to study tx discontinuation in 6 pts. B was stopped in 2 pts due to Gr 3 thromboctyopenia. Of 4 deaths: 2 were PD and 2 were Gr 5 AEs, 1 tx related (PML), 1 tx unrelated. In DLBCL, 88% (28/32) had Gr 3/4 AEs and 63% (20/32) had SAEs. Most common Gr 3/4 non-heme AEs were febrile neutropenia (13%), fatigue (13%), and diarrhea (13%). SAEs occurring in ≥10% of pts were infection (33%) and pyrexia (22%). AEs led to study tx interruption in 19 pts and discontinuation in 8 pts. There were 13 deaths: 9 PD, 4 AE (all unrelated to tx). Responses by modified Lugano 2014 criteria are shown in Table1. Median duration of response (DoR) for FL P1b pts was 16 months (mo)(median fu 14.5 mo). Median DoR for FL P2 (median fu 6.5 mo) and DLBCL P1b/2 (median fu 13.7 mo P1b, 6.4 mo P2) have not been reached.

Table 1.

Table 1. Best Overall Response by PET/CT*

	P1b				P2	
Response	FL		DLBCL		FL	DLBCL
N (%)	Pola+BR (N=6)	Pola+BG (N=6)	Pola+BR (N=6)	Pola+BG (N=6)	Pola+BG (N=20)	Pola+BG (N=21)**
ORR	6 (100)	6 (100)	3 (50)	5 (83)	16 (80)	12 (57)
CR	4 (67)	5 (83)	2 (33)	4 (67)	12 (60)	7 (33)
PR	2 (33)	1 (17)	1 (17)	1 (17)	4 (20)	5 (24)
SD	0	0	0	0	1 (5)	3 (14)
PD	0	0	2 (33)	1 (17)	1 (5)	3 (14)
Unevaluable	0	0	1 (17)	0	2 (10)	3 (14)

*Using Modified Lugano 2014 criteria **1 pt not dosed

Summary/Conclusions: Updated evaluation of pola + BR shows promising durable responses and an acceptable safety profile in heavily pre-treated R/R FL and DLBCL pts. Safety and efficacy data will be updated at the time of presentation.

[1]Institute Jules Bordet, Brussels, Belgium, [2]MD Anderson, Houston, United States, [3]APHP, Hemato-Oncology, Hopital Saint-Louis, Paris, France, [4]Lunenburg Lymphoma Phase–I Consortium, VU University Medical Center, Amsterdam, Netherlands, [5]Taussig Cancer Institute, Cleveland Clinic, Cleveland, United States, [6]Hospital University Virgen del Rocio, Sevilla, Spain, [7]Hospital Pitie Salpetriere, Paris, France, [8]University Hospital Seidman Cancer Center, Cleveland, [9]Feinberg School of Medicine, Northwestern University, Chicago, United States, [10]Hospital Universitario La Paz, Madrid, Spain, [11]Princess Margaret Hospital, Toronto, Canada, [12]NHS Foundation Trust, Cambridge University Teaching Hospitals, Cambridge, United Kingdom, [13]Cliniques Universitaires UCL Saint-Luc, Brussels, Belgium, [14]Karyopharm Therapeutics, Newton, United States, [15]CHU Dijon, Dijon, France

Background: Patients (pts) with persistent DLBCL after two or more lines of therapy have limited effective treatment options. The nuclear export protein exportin 1 (XPO1) is upregulated in hematologic malignancies, including DLBCL, and has pleiotropic effects on tumorigenesis including functional downregulation of tumor suppressor proteins (TSPs) and increased export and translation of mRNAs for oncoproteins c-Myc and key survival proteins such as Bcl-2. Selinexor (SEL), an oral XPO1 inhibitor, causes sequestration of TSPs including p53, p21, and IkBa, the latter of which serves to suppress NF-kB driven transcription, along with reductions in c-Myc and Bcl-2 family proteins. In a Phase I clinical study, pts with relapsed/refractory (R/R) DLBCL treated with SEL presented an overall response rate (ORR) of 32% including 4 CRs. Interestingly, 2 of these pts remain in CR for >1 yr.
Aims: In this clinical study we assess the efficacy of single agent SEL in pts with R/R DLBCL after ≥2 prior regimens.
Methods: Pts with R/R DLBCL were randomized to 60 or 100mg of SEL twice weekly (8 doses) per 28-day cycle. Pts were also stratified by DLBCL subtype (GCB or non-GCB). The primary objectives are to determine the ORR and evaluate the safety of 60 *vs* 100mg doses. Disease response was assessed by an Independent Central Radiological Review (ICRR), using the Lugano Classification (Cheson, 2014).
Results: 72 pts were enrolled: 37 pts on 60mg (24 M/ 13 F, median age 71 yrs) and 35 pts on 100mg (23 M/ 12 F, median age 68 yrs). Both groups had a median of 3 prior treatment regimens. The most common related adverse effects (AEs) across both dosing groups (Grade 1/2) were: fatigue (47%), nausea (46%), anorexia (42%), and vomiting (33%). Common Grade 3/4 AEs were: thrombocytopenia (39%), fatigue (18%), neutropenia (18%), and anemia (13%). These were managed with dose interruption/reduction, platelet stimulators, and/or standard supportive care. Grade 3/4 fatigue (26% v 11%) and thrombocytopenia (46% v 32%) were higher in 100mg arm as compared to the 60mg arm. Among the 63 evaluable pts (9 pts pending response), the ICRR determined ORR was 28.5% (**Table 1**). Nine responders, including 6 pts in CR, remain on treatment. Responders on the 60mg arm have a median time on treatment of 8.9 months as compared with 3.8 months on the 100mg arm.

Table 1. Independent Central Radiological Review-Best Response.

Category	N	ORR (%)	CR (%)	PR (%)	SD (%)	DCR (%)
All Doses	63	18 (28.5%)	7 (11.1%)	11 (17.4%)	9 (14.2%)	27 (42.8%)
60 mg	32	9 (28.1%)	4 (12.5%)	5 (15.6%)	3 (9.3%)	12 (37.5%)
100 mg	31	9 (29%)	3 (9.6%)	6 (19.3%)	6 (19.3%)	15 (48.3%)
GCB-Subtype	32	8 (25%)	3 (9.3%)	5 (15.6%)	6 (18.7%)	14 (43.7%)
Non-GCB Subtype	31	10 (32.2%)	4 (12.9%)	6 (19.3%)	3 (9.6%)	13 (41.9%)

Summary/Conclusions: SEL monotherapy shows activity in pts with R/R DLBCL including in pts with GCB subtype. 60mg SEL twice weekly was more tolerable than 100mg twice weekly, with fewer interruptions due to toxicity. Objective responses to SEL were durable at 60mg BIW, suggesting these responses were associated with clinical benefit.

Seràgnoli", University of Bologna, Bologna, Italy, [12]MorphoSys AG, Planegg, Germany, [13]Hospices Civils de Lyon, Centre Hospitalier Lyon Sud, Service d'Hématologie, Pierre Bénite, France

Background: The Fc-enhanced CD19 antibody MOR208 and the immunomodulatory drug LEN have demonstrated single agent activity in patients with R-R DLBCL. MOR208 and LEN have shown synergy *in vitro* and *in vivo* in preclinical lymphoma models.
Aims: This ongoing phase II study was designed to assess the safety and efficacy of MOR208 plus LEN in patients with R-R DLBCL.
Methods: Patients >18 years of age with R-R DLBCL, ECOG performance status 0-2, adequate organ function, having previously received at least 1 but not more than 3 prior therapies, including at least 1 CD20-targeting regimen and who are not candidates for autologous stem cell transplant (ASCT), are eligible. Treatment comprises up to 12, 28-day cycles of MOR208 12mg/kg IV, administered weekly during cycles 1-3 (loading dose day 4 of cycle 1) and every second week during cycles 4-12 plus LEN 25mg administered po days 1-21 of each cycle. Patients progression-free after 12 cycles receive up to 12 additional cycles of MOR208 12mg/kg IV, administered every second week. The primary endpoint is the overall response rate (ORR) by central radiology assessment. Secondary endpoints include disease control, duration of response, progression-free and overall survival, safety, and response by cell of origin and other biomarkers. A preplanned safety evaluation was undertaken.
Results: 31 of 80 planned patients were enrolled prior to data cutoff (3 January 2017). Median age was 74 years (range 47–82); 45% of patients received ≥2 prior lines of therapy; 23% had rituximab refractory disease; 74% had Ann Arbor stage ≥III disease; 65% had elevated lactate dehydrogenase level, and 52% had a poor revised International Prognostic Index (3–5). The most common treatment-emergent adverse events (any grade/grade ≥3 [% patients]) were neutropenia (39/26), anemia (23/0) thrombocytopenia (16/6), infections (26/10) diarrhea (13/0), pyrexia (13/0), and rashes (13/6). Of 26 response evaluable patients (median follow-up 3.3 months), ORR (investigator assessed) was 58% (15 patients), with 7 (27%) complete responses. Median time to response was 1.8 months.
Summary/Conclusions: The combination of MOR208 plus LEN is well tolerated and shows promising activity in patients with R-R DLBCL. Accrual and follow-up of patients is ongoing, as are cell of origin and other biomarker analyses.

Targeted treatment of AML

S471

ENASIDENIB (AG-221) IN MUTANT-IDH2 RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA (R/R AML): RESULTS OF A PHASE 1 DOSE-ESCALATION AND EXPANSION STUDY

Lurie Comprehensive Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, [9]Dana-Farber Cancer Institute, Boston, [10]Sarah Cannon Research Institute, Nashville, [11]University of Texas Southwestern Medical Center, Dallas, [12]Florida Cancer Specialists and Sarah Cannon Research Institute, Sarasota, [13]City of Hope Comprehensive Cancer Center, Duarte, [14]Cleveland Clinic Taussig Cancer Institute, Cleveland, [15]Sylvester Comprehensive Cancer Center, University of Miami, Miami, [16]Stanford Comprehensive Cancer Center, Stanford University, Stanford, [17]Celgene Corporation, Summit, [18]Agios Pharmaceuticals, Inc., Cambridge, United States, [19]Institut Gustave Roussy, Villejuif, France

Background: Recurrent mutations in *isocitrate dehydrogenase 2* (m*IDH2*) occur in ~12% of AML patients (pts). mIDH2 proteins synthesize an oncometabolite, 2-hydroxyglutarate (2HG), causing DNA and histone hypermethylation and blocked myeloid differentiation. Enasidenib (AG-221) is an oral, selective, small-molecule inhibitor of mIDH2 proteins. Differentiation of myeloblasts, not cytotoxicity, appears to drive the clinical efficacy of enasidenib. In preclinical studies, bone marrow blasts from pts with m*IDH2* AML exposed to enasidenib *ex vivo* were shown to produce mature, fully functioning neutrophils with conserved m*IDH2* allele frequency, indicating differentiation of mature cells from the m*IDH2* blasts (Yen et al, *Cancer Discov*, 2017). Additionally, no apoptosis was observed in m*IDH2*-R140 erythroleukemia (TF-1) cells treated with enasidenib for 7 days *in vitro*.

Table 1.

Table. Investigator-reported hematologic responses, time to response, and response durations

	Relapsed or refractory AML	
	Enasidenib 100mg/day (n=109)	All doses (N=176)
Overall response rate,* no. (%) [95% CI]	**42 (38.5)** [29.4, 48.3]	**71 (40.3)** [33.0, 48.0]
Best response		
Complete remission, *no. (%) [95% CI]*	**22 (20.2)** [13.1, 28.9]	**34 (19.3)** [13.8, 25.9]
CR with incomplete hematologic recovery / CR with incomplete platelet recovery, *no. (%)*	7 (6.4)	12 (6.8)
Partial remission, *no. (%)*	3 (2.8)	11 (6.3)
Morphologic leukemia-free state, *no. (%)*	10 (9.2)	14 (8.0)
Stable disease,† *no. (%)*	58 (53.2)	85 (48.3)
Progressive disease, *no. (%)*	5 (4.6)	9 (5.1)
Not evaluable, *no. (%)*	2 (1.8)	3 (1. 7)
Time to first response, *median (Range)*	1.9 months (0.5-9.4)	1.9 months (0.5-9.4)
Duration of response, *median [95% CI]*	5.6 months [3.8, 9.7]	5.8 months [3.9, 7.4]
Time to complete remission, *median (Range)*	3.7 months (0.7-11.2)	3.8 months (0.5-11.2)
Duration of response in patients who attained complete remission,‡ *median [95% CI]*	8.8 months [5.3, NR]	8.8 months [6.4, NR]

Responses were evaluated by study investigators and classified according to the 2003 revised IWG criteria for AML.
*Includes patients with complete remission (CR), CR with incomplete hematologic recovery, CR with incomplete platelet recovery, partial remission, or morphologic leukemia-free state
†Stable disease was defined as failure to achieve a response but not meeting criteria for disease progression for a period of more than 8 weeks
‡Date of first documented response to date of relapse, disease progression, or death.
95% CI, 95% confidence interval; CR, complete remission; NR, not reached

Aims: Evaluate the maximum tolerated dose (MTD), pharmacokinetic (PK) and pharmacodynamic (PD) profiles, safety, and clinical activity of enasidenib in pts with m*IDH2* advanced myeloid malignancies.
Methods: This phase 1/2 study included pts aged ≥18 years (yrs) with m*IDH2* WHO-defined AML, or with m*IDH2* MDS with refractory anemia with excess blasts, and ECOG PS scores ≤2. Pts were relapsed or refractory (R/R) to prior anti-cancer therapy, or had untreated AML if aged ≥60 years and not eligible for standard-of-care treatment (Tx). Safety for all pts and clinical efficacy in the largest pt subgroup, those with R/R AML, from the phase 1 dose-escalation and expansion phases are reported.
Results: In all, 239 pts received enasidenib. Median age was 70 yrs. In the dose-escalation phase (n=113), pts received daily enasidenib doses of 50-650mg. The MTD was not reached. Median 2HG reductions from baseline at cycle 2 day 1 were 92%, 90%, and 93% for pts receiving <100mg, 100mg, and >100mg/day, respectively. Enasidenib 100mg QD was chosen for the expansion phase (n=126) based on PK/PD profiles and demonstrated efficacy. Median number of enasidenib cycles was 5 (range 1-25). Grade 3-4 investigator-reported Tx-related adverse events included indirect hyperbilirubinemia (12%) and IDH-inhibitor-associated differentiation syndrome (IDH-DS; ie, retinoic acid syndrome) (7%). Of 176 R/R AML pts, 94 (53%) had received ≥2 prior AML-directed Tx. Overall response rate (ORR; complete remission [CR] + CR with incomplete hematologic recovery + morphologic leukemia-free state + partial remission) in R/R AML pts was 40.3%, including 34 pts (19.3%) who attained CR (**Table**). Median time to 1st response was 1.9 months (mos); 87.3% of responding pts attained a 1st response by cycle 5. Median response duration was 5.8 mos. Of pts who achieved CR, 7 pts (21%) did so by cycle 3, 23 (68%) by cycle 5, and 28 (82%) by cycle 7. Median duration of CR was 8.8 mos. ORR with enasidenib 100mg/day was 38.5% (**Table**). Seventeen pts (11%) proceeded to stem cell transplant. Response was associated with cellular differentiation, typically with no evidence of aplasia. Median overall survival (OS) of R/R AML pts was 9.3 mos. For pts who attained CR, OS was 19.7 mos. Pts who had received ≥2 prior AML Tx had a median OS of 8.0 mos.
Summary/Conclusions: Enasidenib was well tolerated, induced CRs in R/R AML pts, and was associated with OS of >9 mos in pts who had failed prior AML Tx. A randomized phase 3 study of enasidenib *vs* conventional care in older pts with late-stage R/R AML is ongoing (NCT02577406).

S472

SAFETY AND EFFICACY OF VENETOCLAX (VEN) IN COMBINATION WITH DECITABINE OR AZACITIDINE IN TREATMENT-NAIVE, ELDERLY PATIENTS (≥65 YEARS) WITH ACUTE MYELOID LEUKEMIA (AML)

Background: Newly diagnosed patients (pts) with AML aged ≥65 years and ineligible for standard induction therapy have limited treatment options, and low overall survival. VEN is an orally bioavailable, selective BCL-2 inhibitor that has displayed single-agent activity in pts with relapsed/refractory AML. VEN at escalating doses combined with hypomethylating agents (HMAs) has demonstrated antileukemic activity, with an overall response rate (ORR) including complete remission [CR], and CR with incomplete marrow recovery of 60%. Combining VEN with HMAs, such as decitabine (DEC) or azacitidine (AZA), may provide a novel low-intensity approach for treating AML. Preliminary results from the expansion stage of a phase 1b trial comparing 2 doses of VEN plus either DEC or AZA (NCT02203773) are reported.
Aims: To evaluate the safety and efficacy of VEN at 400-mg *vs* 800-mg doses plus DEC or AZA.
Methods: This open-label, nonrandomized, two-stage phase 1b study evaluated the safety and efficacy of VEN plus DEC or AZA in treatment-naive pts ≥65 years with AML. Eligibility included: ECOG PS ≤2; ineligible for standard induction therapy; intermediate- or poor-risk karyotype. Pts received DEC (Arm D, 20mg/m^2/day [d];intravenous [IV]) on d 1–5, or AZA (Arm E, 75mg/m^2/d; subcutaneous or IV) on d 1–7 of each 28-d cycle (C) in combination with once-daily oral VEN. The dose-expansion stage consisted of 2 VEN dose cohorts (continuous 400-mg and interrupted 800-mg dosing) in each arm (D1, D2, E1, and E2, respectively) to determine optimal dose. Tumor lysis syndrome (TLS) prophylaxis was administered in C1 to all pts during VEN dose ramp-up until final dose was reached. All pts provided informed consent.

Results: As of 13/09/16, 100 pts were enrolled in the expansion stage: 25 pts in each arm. Overall, 61% pts were male; 59% had ECOG PS 1 and 15% ECOG PS 2; mean age was 73.9 (range 65–86); 53% had adverse karyotype; and 22% had secondary AML. Median time on study was 6 (4-9), 6 (0.2-9), 5 (0.5-9), and 4 (1-8) mo for arms D1, D2, E1, and E2, respectively. The incidence of adverse events (AEs) was generally comparable between the 4 arms. Overall, the most common treatment-emergent AEs (TEAEs; in ≥30% of pts) were nausea (59%), diarrhea (42%), febrile neutropenia (FN; 41%), constipation (39%), fatigue, and decreased white blood cell count (31% each). The most frequent grade 3/4 TEAE and serious AE was FN (41% and 29%, respectively). No TLS was observed. Overall, 29 pts discontinued the study for ≥1 reason, including progressive disease (PD) per protocol (n=10), "other" (n=10; 9/10 proceeded to stem cell transplantation) and AEs not related to progression (n=10). A total of 16 deaths occurred; 12 pts died within 30 d of initiating VEN and HMA due to AEs (n=12) and PD (n=1). The ORR was 68%, with rates of 76% (19/25), 71% (17/24), 68% (17/25), and 60% (15/25) observed in arms D1, D2, E1, and E2, respectively. The Kaplan-Meier survival curve for all pts with a median follow-up time of 5.4 mo is shown.

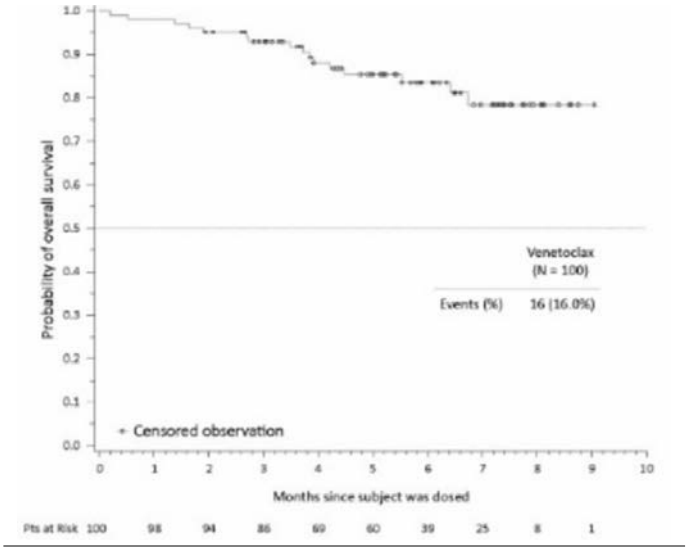

Figure 1.

Summary/Conclusions: Overall, the safety profile was favorable when combining VEN at either dose with DEC or AZA in treatment-naive elderly AML pts. Promising activity with high ORRs was observed at the lower 400-mg VEN dose in both HMA arms. A Phase 3 study of VEN plus AZA is planned.

S473

UPDATED SAFETY AND EFFICACY RESULTS OF PHASE 1/2 STUDY OF VENETOCLAX PLUS LOW-DOSE CYTARABINE IN TREATMENT-NAÏVE ACUTE MYELOID LEUKEMIA PATIENTS AGED ≥65 YEARS AND UNFIT FOR STANDARD INDUCTION THERAPY

A.H. Wei[1,*], S.A. Strickland[2], G.J. Roboz[3], J.-Z. Hou[4], W. Fiedler[5], T.L. Lin[6], G. Martinelli[7], R.B. Walter[8], A. Enjeti[9], K.M. Fakouhi[10], D.E. Darden[10], M. Dunbar[10], T. Xu[10], M. Mabry[10], J. Hayslip[10]

[1]The Alfred Hospital and Monash University, Melbourne, Australia, [2]Vanderbilt-Ingram Cancer Center, Nashville, [3]Weill Cornell Medical College, New York, [4]University of Pittsburgh Medical Center (UPMC) Cancer Center, Pittsburgh, United States, [5]Hubertus Wald University Cancer Center, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [6]University of Kansas Medical Center, Kansas City, United States, [7]Bologna University School of Medicine, Bologna, Italy, [8]University of Washington, Seattle, and Fred Hutchinson Cancer Research Center, Seattle, United States, [9]Calvary Mater Hospital Newcastle and School of Medicine and Public Health, University of Newcastle, Callaghan, Waratah, Australia, [10]AbbVie, Inc, North Chicago, United States

Background: Incidence of acute myeloid leukemia (AML) increases with age, and patients (pts) ≥65 years have a poor prognosis, with 5-year survival rates of <10%. Treatment with low-dose cytarabine (LDAC) in this population results in modest complete remission (CR)/CR with incomplete blood count recovery (CRi) rates of 11-19% and median survival of 5-6 months. Venetoclax (VEN), an orally bioavailable, potent, selective BCL-2 inhibitor, has shown single-agent activity in heavily pretreated pts with relapsed/refractory AML (Konopleva et al 2016). In combination with LDAC, the recommended phase 2 dose (RP2D) of VEN is 600mg QD (Lin et al, ASCO 2016); preliminary data show the combination is tolerable and exhibits significant and durable activity in older AML pts ineligible to receive intensive induction chemotherapy (Wei et al, ASH 2016). Updated safety and efficacy data from the RP2D 600-mg dose cohorts of this study (NCT02287233) are presented.

Aims: Evaluate the safety and efficacy of VEN+LDAC in older pts with untreated AML.

Methods: In this open-label phase 1/2 study, pts ≥65 years with untreated AML, ineligible for standard induction chemotherapy, with an ECOG performance status of 0-2 received oral VEN QD on days (d) 1-28 and subcutaneous LDAC 20mg/m^2 QD on d 1–10 of each 28-d cycle. VEN target dose evaluation followed a 3+3 design, ranging from 600–800mg; 18 pts were enrolled and the RP2D was established as 600mg. Safety and efficacy of VEN at RP2D were evaluated in the expansion phase. All pts were hospitalized and received prophylaxis before a dose ramp-up of VEN during cycle 1 to mitigate the risk of tumor lysis syndrome (TLS). Adverse events (AEs) were graded by NCI CTCAE V4.0. Pts enrolled as of May 2016 are included in this analysis; data cutoff was August 2016. All pts provided informed consent.

Results: In total, 61 pts, including 8 from phase 1, were treated at the RP2D of 600mg (median age 74 years; ECOG 1–2 70%; adverse karyotypes 31%; secondary AML 44%; prior hypomethylating agent [HMA] 28%). AEs (all grade; ≥30% pts; excluding cytopenias) were nausea (72%), hypokalemia (46%), diarrhea (44%), fatigue (43%), and decreased appetite (41%). Grade 3/4 AEs (≥10% pts) were febrile neutropenia (34%), hypokalemia (15%), hypophosphatemia (13%), and hypertension (10%). No pts had clinical TLS; 1 pt had laboratory TLS, which was managed. The 30-d and 60-d mortality rates were 3% and 15%, respectively. The CR/CRi rate was 54% (33/61; 21% CR and 33% CRi). The overall response rate (ORR; CR+CRi+partial remission) was 61% (37/61). VEN+LDAC was shown to be active across a wide range of cytogenetic mutations and pt profiles (ORR: 70% in pts ≥75 years; 52% in secondary AML; 47% in pts with adverse karyotypes; 53% in pts with prior HMA). Among response-evaluable pts, those achieving an objective response have longer survival than pts who do not achieve an objective response (Figure 1).

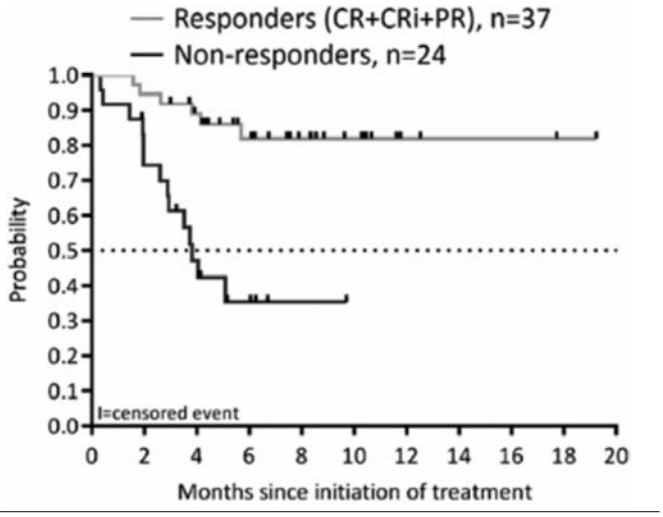

Figure 1.

Summary/Conclusions: VEN (RP2D 600mg) and LDAC exhibited an acceptable safety profile and durable efficacy in pts aged ≥65 years with untreated AML who are ineligible for or unable to receive intensive induction chemotherapy. ORR highly correlated with overall survival, with better survival observed in responders compared with nonresponders. A planned phase 3 randomized trial has commenced.

S474

PHASE IB/II STUDY OF NIVOLUMAB IN COMBINATION WITH AZACYTIDINE (AZA) IN PATIENTS (PTS) WITH RELAPSED ACUTE MYELOID LEUKEMIA (AML)

N. Daver[1,*], S. Basu[2], G. Garcia-Manero[1], J. Cortes[1], F. Ravandi[1], E. Jabbour[1], N. Pemmaraju [1], S. Hendrickson[1], T. Gordon[1], M. Brandt[1], S. Pierce[1], J. Matthews[1], S. Kornblau[1], W. Flores[1], M. Konopleva[1], H. Kantarjian[1], P. Sharma[3]

[1]Department of Leukemia, University of Texas MD Anderson Cancer Center, [2]Immunotherapy Platform, MDACC, [3]Immunotherapy Platform, University of Texas MD Anderson Cancer Center, Houston, United States

Background: Blocking PD-1/PD-L1 pathways enhances anti-leukemia responses in murine AML (Zhang et al, Blood 2009). PD-1 positive CD8 T-cells are increased in bone marrow (BM) of pts with AML (Daver et al, AACR 2016). AZA up-regulates PD-1 and interferon-gamma signaling in AML and the up-regulation of PD-1 has been associated with emergence of resistance to AZA (Yang *et al.*, Leukemia 2013).

Aims: To assess the best response to Aza+Nivo at the end of 3 courses of combination therapy.

Methods: Pts were eligible if they had AML and failed prior therapy, had adequate performance status (ECOG ≤2), and organ function. The first six pts

received AZA 75mg/m^2 Days 1-7 with nivolumab 3mg/kg on Day 1 and 14. Courses were repeated every 4-5 weeks indefinitely. Only one of six pts had a dose limiting toxicity (grade 3 pneumonitis) and this dose was RP2D. 60 additional pts have been treated at the RP2D.

Results: 66 pts with a median age of 71 years (range, 44-90), secondary AML (39%), poor risk cytogenetics (35%), median number of prior regimens 2 (range, 1-7) have been enrolled. All 66 pts had baseline next generation sequencing: TP53 (n=14), DNMT3A (n=12), ASXL1 (n=10), TET2 (N=9), and RAS (n=9), IDH2 (n=9), IDH1 (n=6), CEBPA (n=7). 63 pts are evaluable for response: 14 (22%) achieved complete remission (CR)/complete remission with insufficient recovery of counts (CRi) (3 CR, 11 CRi), 7 (11%) had hematologic improvement (HI), 13 (21%) had ≥50% BM blast reduction, 5 pts (8%) had stable disease >6 months, and 24 (38%) had progression. 3 pts are too early for response assessment (<3 courses). The median number of courses to CR/CRi/HI was 2 (range, 1-4+). The med OS among the CR/CRi patients was 15.3 months (range, 2.29-17.25+), HI pts was 9.7 months (range, 4.67-17.45+), and NR was 5.0 months (range, 0.29-16.16). The 4- and 8-week mortality were 5% and 11%, respectively. The median OS for the 63 evaluable pts on Aza+Nivo compares favorably to historical median OS with AZA-based salvage protocols in similar pts treated at MDACC (P=0.10) (Fig 1A and Fig 1B). Grade 3/4 and Grade 2 immune toxicities were observed in 8 (12%) and 7 (11%) pts, respectively. The most common Grade 3/4 AEs on treatment included pneumonitis, colitis, nephritis, skin rash, and hypophysitis. One pt died from grade 4 pneumonitis/epiglottitis. In the remaining 14 cases the toxicities responded rapidly to steroids and 13 of these pts were successfully rechallenged with nivolumab. Time to onset of toxicities ranged from 4 days to 3.5 months. Multicolor flow-cytometry studies and Mass-cytometry (CyTOF) studies are conducted by the Immunotherapy Platform on baseline and on-treatment BM aspirate (end of cycle 1, 2, 4, 8). Baseline and end of cycle (EOC) 1 and 2 BM was evaluated in 6 responders and 19 non-responders. Pts who achieved a response had a baseline higher live total CD3 (P=0.10), CD8$^+$ T-cells (P=0.02), and lower live CD4$^+$Foxp3$^+$PD1$^+$ T-regulatory (T-reg) cells (P=0.01) infiltrate in BM. Patients who had a response had progressive increase in BM CD3+ cells and BM CD8+ cells, with increased ICOS (activation) marker on BM CD4-effector cells at EOC 1 and EOC 2 as compared to those who had no response. The CTLA4 on CD8 T-cells went up in both responders and non-responders after PD1 based therapy.

Figure 1. OS with Aza+Nivo compared to historical survival with AZA-based salvage protocols in similar pts treated at MDACC in (a) all salvage and (b) first salvage only

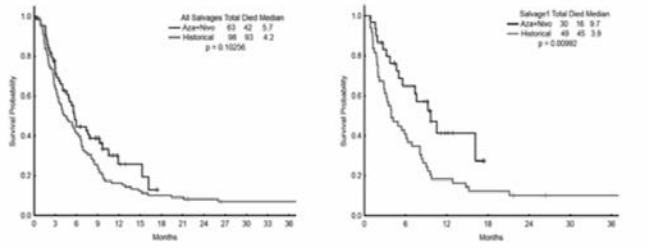

Figure 1.

Summary/Conclusions: Full dose AZA and nivolumab are tolerable and produce an encouraging response rate with durable responses in relapsed AML with poor risk features. Immune mediated toxicities occur and may be adequately managed with early recognition and systemic steroids. Up-regulation of CTLA4 may be a mechanism of resistance to PD1 based therapies in AML and suggest role for combination therapy.

S475

QUIZARTINIB AND BRIDGE TO TRANSPLANT IN FLT3-ITD AML PATIENTS AFTER FAILURE OF SALVAGE CHEMOTHERAPY: A HISTORICAL COMPARISON WITH UK NATIONAL CANCER RESEARCH INSTITUTE (NCRI) DATA

R. Hills[1,*], G. Gammon[2], D. Trone[3], A. Burnett[4]
[1]Centre for Trials Research, Cardiff University, Cardiff, United Kingdom, [2]formerly Daiichi Sankyo, [3]Daiichi Sankyo, San Diego, United States, [4]Blackwaterfoot, Isle of Arran, United Kingdom

Background: The presence of a FMS-like tyrosine kinase 3 (FLT3) Internal Tandem Duplication (ITD) mutation in pts with AML is associated with an increased early relapse rate and a dismal prognosis. Quizartinib is a potent, selective oral FLT3 receptor tyrosine kinase inhibitor that conferred median OS (mOS) of 23 weeks and remission rate of 46% in a single-arm phase 2 study (AC220-002) in pts with AML with a FLT3-ITD mutation who were relapsed or refractory (R/R) to second line therapy. (Levis, *et al.*, ASH 2012) As context, a study of AML pts, regardless of FLT3 mutation status, receiving second-salvage therapy reported mOS of only 1.5 months. (Giles F, *et al. Cancer* 104 (3), 2005). Such poor-risk pts may benefit from a stem cell transplant (SCT), if available.
Aims: The primary aim was to compare SCT rates and outcomes of pts on quizartinib from an exploratory selected cohort in the AC220-002 study with those from a historical cohort of 1388 AML pts with confirmed FLT3-ITD mutations in the UK NCRI database.
Methods: Within AC220-002, 58 pts with a FLT3-ITD mutation were identified who had received intensive chemotherapy, and were relapsed (n=53), or refractory (n=5) to salvage therapy prior to entry. Applying the same entry criteria to the NCRI database, we identified 118 pts who received only recognized chemotherapy regimens prior to eligibility (relapsed n=99; refractory n=19). To avoid biases where those dying early would predominantly contribute to the NCRI group (reflecting that pts in AC220-002 had to be fit enough to be enrolled), pts in this cohort entered analysis 14 days following being identified as R/R. Multivariable Cox/logistic regression was used to compare remission rates and survival stratified for known prognostic factors. A landmark analysis excluding deaths before day 90 (allowing for those too unfit for SCT) was performed on the pooled sample (n=176) of the AC220-002 and NCRI cohorts to compare survival between transplanted and non-transplanted pts.
Results: Overall, quizartinib-treated pts had significantly greater remission rates, consisting mainly of complete remission without normal blood counts (CRi), *vs* NCRI pts (40% *vs* 3%, adjusted OR 0.05 (0.01-0.21), p<0.0001) and improved mOS (140d *vs* 54d, adjusted HR 0.38 (0.25-0.58) p<.0001). A greater proportion of pts in AC220-002 proceeded to SCT: 23/58 (40%) *vs* 9/118 (8%). Comparing survival in SCT *vs* no-SCT in a landmark analysis, 18-month survival was significantly greater in the SCT group (29% *vs* 7%, adjusted HR 0.36 (0.20-0.65) p=0.0005). Significance persisted in sensitivity analyses with the landmark set at 120 or 150 days indicating an association between long-term survival and SCT. A similar analysis in an unmatched cohort consisting of SCT-naïve pts in first relapse also found better survival for SCT *vs* no-SCT, confirming a potential benefit of SCT in this poor risk population.
Summary/Conclusions: When compared to a large historical cohort, quizartinib was associated with greater remission rates and opportunity to receive SCT in pts who relapsed after salvage therapy. While varying practice patterns and patient factors obviously influence treatment choices and outcomes, pts with AML with FLT3-ITD mutation appeared to benefit with longer survival observed with SCT. This data suggests quizartinib may show promise in potentially improving long-term survival by bridging patients to SCT.

Immunotherapy in ALL

Background: The CD19-targeted chimeric antigen receptor (CAR) T-cell therapy CTL019, an investigational therapy that reprograms cytotoxic T cells to eliminate target cells, resulted in high response rates and a manageable safety profile in pediatric/young adult patients (pts) with R/R B-cell ALL in a single-center trial.
Aims: We report an updated interim analysis from the first multicenter global pivotal registration trial of a CAR T-cell therapy (ELIANA; NCT02435849) including data for 68 pts infused with CTL019, 50 of whom were followed for ≥6 mo.
Methods: This is a single-arm, open-label, multicenter, global, phase 2 study of CTL019 in pediatric/young adult pts with CD19+ R/R B-cell ALL with ≥5% bone marrow lymphoblasts by morphology. CTL019 was manufactured from leukapheresed autologous peripheral blood T cells at a centralized manufacturing facility. The primary endpoint was overall remission rate (complete remission [CR] + CR with incomplete blood count recovery [CRi]) within 3 mo. Secondary endpoints included duration of remission (DOR), overall survival, safety, and cellular kinetics.
Results: As of November 2016, 88 pts were enrolled. There were 7 (8%) manufacturing failures, 9 (10%) pts were not infused due to death or adverse events (AEs), and 4 pts (5%) were pending infusion at the time of data cutoff. Following lymphodepleting chemotherapy in most pts (fludarabine/cyclophosphamide [n=64]) or other [n=1]), 68 pts were infused with a single dose of CTL019 (median dose, 3.0×10^6 [range, 0.2-5.4×10^6] transduced CTL019 cells/kg), with a median study follow-up of 6.4 mo. Median age was 12 y (range, 3-23 y); 59% of pts had prior allogeneic stem cell transplant (alloSCT). Five infused patients had not reached 3 mo of follow-up; among 63 evaluable pts, 52 (83% [95% CI, 71%-91%]) achieved CR/CRi within 3 mo of CTL019 infusion, all of whom had minimal residual disease–negative marrow. The relapse-free probability at 6 mo after remission onset was 75% (95% CI, 57%-87%; median DOR not reached). The probability of survival was 89% (95% CI, 77%-94%) at 6 mo and 79% (95% CI, 63%-89%) at 12 mo. Seven pts (13% of responders) proceeded to alloSCT within 6 months while in remission. Cytokine release syndrome (CRS) was graded using the UPenn scale and managed using a protocol-specific algorithm; CRS occurred in 78% of pts (21% grade 3; 27% grade 4); no CRS-associated deaths occurred. 38% of pts received tocilizumab for treatment of CRS with or without other anti-cytokine therapy. Most common grade 3/4 nonhematologic AEs (>15%) other than CRS were hypotension (22%), hypoxia (18%), and increased aspartate aminotransferase (16%). The incidence of serious AEs within 8 weeks of infusion was 69%. 15% of pts experienced grade 3 neuropsychiatric AEs, with no grade 4 events and no cerebral edema reported. Grade 3/4 neutropenia with high (>38.3°C) fever occurred in 60% of pts. 2 pts died within 30 days of infusion (ALL progression, n=1; cerebral hemorrhage, n=1), and 9 pts died >30 days after infusion (ALL relapse/progression, n=6; HHV-6 encephalitis, pneumonia, systemic mycosis, n=1 each). CTL019 expansion *in vivo* correlated with CRS severity, and persistence of CTL019 along with B-cell aplasia in peripheral blood was observed for ≥1 year in some responders.
Summary/Conclusions: The ELIANA study confirmed the efficacy of a single infusion of CTL019, without additional therapy, observed in a previous interim analysis and a prior single-center CTL019 trial. AEs were effectively and reproducibly managed globally by appropriately trained personnel at study sites.

Background: CTL019 is an investigational therapy whereby autologous T cells are genetically engineered with a chimeric antigen receptor (CAR) to identify and eliminate CD19-expressing malignant B cells. Data from 2 phase 2 studies (ELIANA; NCT02435849 and ENSIGN; NCT02228096) in pediatric and young adult R/R B-cell ALL were pooled to evaluate cellular kinetics of CTL019.
Aims: We report cellular kinetics, humoral immunogenicity, AUC0-28d (exposure)-response analysis and impact of intrinsic/extrinsic and manufacturing factors on CTL019 expansion.
Methods: Cellular kinetic parameters of CTL019 post infusion were derived using traditional pharmacokinetic principles and reported by response category (complete response [CR]/CR with incomplete blood count recovery [CRi] *vs* no response [NR]) using 2 assays of peripheral blood cells: qPCR and flow cytometry. AUC0-28d-response relationships were evaluated by logistic regression. Relationships between manufacturing specifications, therapies for cytokine release syndrome (CRS) management, and anti-CAR19 antibodies on cellular kinetics were explored using summary statistics and graphical- and model-based analyses.

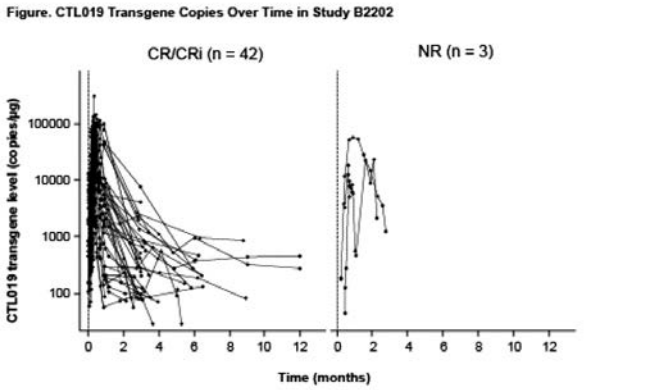

Figure 1.

Results: Data from 79 pts (ELIANA, n=50; ENSIGN, n=29) were pooled for analysis. Using qPCR, pts with CR/CRi (n=62) had ≈ 2-fold higher CTL019 expansion than pts with NR (n=7) (Cmax, 73.5% higher geometric [geo] mean; AUC0-28d, 104% higher geo mean; **Table 1**). Pts with NR had delayed Tmax compared with pts with CR/CRi (20 *vs* 10 days). Intrinsic pt factors including baseline cytogenetics, disease characteristics, and disease status did not appear to affect Cmax or AUC0-28d with the exception that pts with a higher tumor burden at enrollment generally had higher expansion, based on box plots and summary statistics. Extrinsic factors (prior lines of therapy, stem cell transplant) and parameters related to the manufactured product (% T cells, transduction efficiency, cell viability, total cell count), did not appear to impact cellular kinetics, based on graphical analysis. AUC0-28d increased with pres-

ence and severity of CRS. Pts who received anti-cytokine agents for grade 3/4 CRS also had higher expansion. CR/CRi pts treated with tocilizumab and steroids (n=17) had 89% higher AUC0-28d than CR pts who did not receive tocilizumab and steroids (n=45). Experience is limited in NR pts with (n=4) and without (n=4) tocilizumab. Moderate correlation was observed between transgene levels and CAR surface expression in peripheral blood (r^2=0.592) by qPCR and flow cytometry, respectively, when matched by time points from the cellular kinetic profile. Slower B-cell recovery was observed in pts with AUC0-28d above the median. Post-dose anti-CAR19 antibody responses were determined from the fold change of anti-CAR19 antibodies above the baseline predose value. Pts with treatment-induced or boosted anti-CAR19 antibody responses generally had lower expansion, based on box plots, compared with pts with treatment-unaffected anti-CAR19 antibody responses, although AUC0-28d was variable. The boosted levels of anti-CAR19 did not impact clinical response or relapse.

Table 1.

Table. Summary of Cellular Kinetic Parameters for CTL019 by qPCR by Day 28 Response

Parameter	Statistics	CR/CRi (n = 62)	NR (n = 7)
AUC0-28d (copies/µg DNA × days)	n	61	6
	CR/CRi fold change over NR	2.0	
Cmax (copies/µg)	n	61	7
	CR/CRi fold change over NR	1.7	
Tmax (days)	n	61	7
	Median (range)	9.91 (0.00764-27.0)	20.0 (0.0278-62.7)
T1/2 (days)	n	54	3
	Median (range)	14.8 (2.03-206)	1.48 (1.12-9.65)

• Unknown response, n = 10

Summary/Conclusions: There was increased expansion of CTL019 in pts with higher tumor burden at enrollment, which correlated with higher CRS grade. There was no relationship between dose and expansion, supporting the wide dose range used. Expansion was not attenuated by tocilizumab or steroids, indicating therapies for CRS do not abrogate CTL019 proliferation. Cellular kinetics are important to understand the determinants of tumor response with CAR T-cell therapy.

BLINATUMOMAB *VS* SOC CHEMOTHERAPY IN FIRST SALVAGE COMPARED WITH SECOND OR GREATER SALVAGE IN A PHASE 3 STUDY

H. Dombret[1,*], M.S. Topp[2], A. Schuh[3], A. Wei[4], G. Martinelli[5], S. Durrant[6], C.L. Bacon[7], K. Nie[8], Z. Zimmerman[9], H. Kantarjian[10]
[1]Hôpital Saint-Louis, Paris, France, [2]Universitätsklinikums Würzburg, Würzburg, Germany, [3]Princess Margaret Cancer Center, University Health Network, Toronto, Canada, [4]Alfred Hospital, Monash University, Victoria, Australia, [5]Institute of Hematology and Medical Oncology "L. e A. Seragnoili", S. Orsola University Hospital, Bologna, Italy, [6]Clinical Haematology and BMT, Royal Brisbane Hospital, Herston, Australia, [7]St. James's Hospital, Dublin, Ireland, [8]Global Biostatistical Sciences, [9]Global Development, Amgen, Thousand Oaks, [10]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Adults with B-cell precursor (BCP) acute lymphoblastic leukemia (ALL) often relapse following standard induction/consolidation chemotherapy (CTX). Prognosis following second and successive CTX salvage regimens (S2+) is poor compared with first salvage (S1) or frontline therapy, with less favorable outcomes among patients with shorter CR duration. Blinatumomab links cytotoxic CD3-positive T cells and CD19-positive B cells to induce tumor cell lysis. In a randomized phase 3 trial of blinatumomab *vs* investigator's choice of 4 standard of care CTX (SOC) regimens, median OS was 7.7 months in the blinatumomab group *vs* 4.0 months with SOC (Kantarjian H, *et al.*, NEJM 2017). Here, we evaluate outcomes by salvage status for patients in this study (NCT02013167).
Aims: To evaluate responses to blinatumomab *vs* SOC in patients with relapsed/refractory ALL by prior salvage therapy status.
Methods: Patients with relapsed/refractory (R/R) BCP-ALL in this international multicenter trial were randomized 2:1 to blinatumomab (n=271) or SOC (n=134). For this analysis, salvage status was adjudicated separately from prior randomization strata. Blinatumomab was given by continuous IV infusion (9 µg/d in week 1 of cycle 1, then 28 µg/d) in cycles of 4 weeks on, 2 weeks off. The primary endpoint was overall survival (OS), determined from time of randomization until death due to any cause. Adverse events (AE) of interest were coded according to MedDRA version 16.0.
Results: At baseline, patient characteristics were balanced between groups within salvage designations. The rate of complete remission, with or without full hematologic recovery (CR/CRh/CRi) in both the S1 and S2+ groups was higher in the blinatumomab arm compared with the SOC arm (Table 1). Patients randomized to blinatumomab had a median (95% CI) of 11.1 (8.2, NR) months *vs* 5.1 (3.2, 7.1) months overall survival for S1 *vs* S2+ subgroup, compared with 5.5 (3.7, 9.0) months *vs* 3.0 (2.1, 4.0) months in the SOC arm (Figure 1). For both S1 and S2+ subgroups, blinatumomab patients had longer median survival time. Grade 3 or worse AEs were experienced by 61% and 83% of S1 patients in the blinatumomab and SOC group, respectively. These percentages were 68% and 75%, respectively, in S2+ patients. Grade 4 or worse AEs occurred in 34% and 51% S1 patients, and in 36% and 54% S2+ patients. Neurologic events of grade ≥3 occurred in 9% and 9% of S1 patients, and in 10% and 9% S2+ patients, respectively. Grade ≥3 cytokine release syndrome (CRS) was observed in 4% S1 and 5% S2+ patients receiving blinatumomab, and in no SOC patients.

Table 1.

	No prior salvage (S1)		Any prior salvage (S2+)	
	Blinatumomab (n=104)	SOC (n=63)	Blinatumomab (n=167)	SOC (n=71)
Age ≥35 years, n (%)	65 (62.5)	37 (58.7)	82 (49.1)	37 (52.1)
Prior HSCT, n (%)	29 (27.9)	20 (31.7)	65 (38.9)	26 (36.6)
First relapse with remission duration <12 mo, n (%)	58 (55.8)	30 (47.6)	51 (30.5)	19 (26.8)
Maximum blasts ≥50% by central/local lab, n (%)	78 (75.0)	45 (71.4)	123 (73.7)	59 (83.1)
K-M Median OS, mo (95% CI)	11.1 (8.2, NR)*	5.5 (3.7, 9.0)	5.1 (3.2, 7.1)	3.0 (2.1, 4.0)
	HR 0.59 (95% CI 0.38, 0.91) P=0.016		HR 0.72 (95% CI 0.51, 1.01) P=0.055	
Best response (CR/CR/CRi), n (%) [95% CI]	53 (51.0) [41.0, 60.9]	23 (36.5) [24.7, 49.6]	66 (39.5) [32.1, 47.4]	10 (14.1) [7.0, 24.4]
	P=0.07		P<0.001	

**NR=not reached*

Figure. Overall survival among patients with no (S1) or prior (S2+) salvage treatment

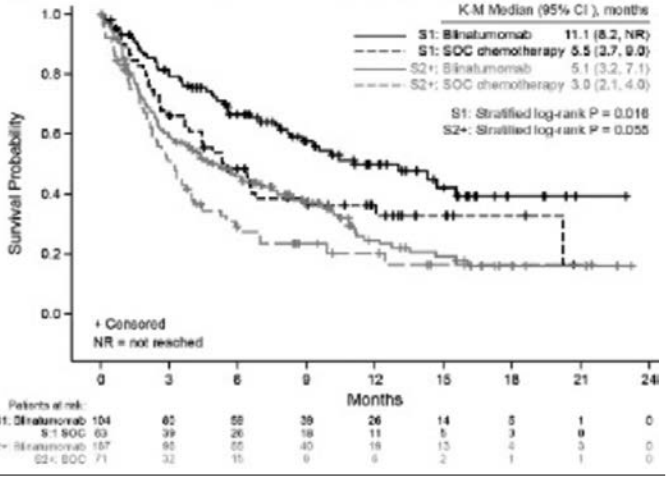

Figure 1.

Summary/Conclusions: Patients in this trial receiving blinatumomab for R/R ALL achieved improved OS and remission rates compared with SOC regardless of prior salvage therapy. Improved OS compared with SOC in S1 patients supports earlier use of blinatumomab.

S479

DURABLE LONG-TERM SURVIVAL OF ADULT PATIENTS WITH B-ALL AFTER CD19 CAR (19-28Z) T CELL THERAPY

J. Park[1,*], I. Riviere [1], X. Wang[1], B. Senechal[1], Y. Wang[1], T. Purdon[1], R. Brentjens[1], M. Sadelain[1]
[1]Memorial Sloan-Kettering Cancer Center, New York, United States

Background: CD19-specific chimeric antigen receptor (CAR) T cells have demonstrated high initial responses in patients with relapsed B-ALL. However, clinical characteristics associated with the durability of response remain undefined.
Aims: We performed a retrospecive analysis of our phase I clinical trial of 19-28z CAR T cells in adult patients with relapsed B-ALL (NCT01044069) with a focus to identify those patients who optimally benefit from 19-28z CAR T cell therapy with durable long-term survival and reduced toxicities.
Methods: Adults with relapsed B-ALL were infused with autologous T cells expressing the 19-28z CAR following conditioning chemotherapy. Disease burden was assessed by bone marrow biopsy immediately prior to T cell infusion; patients with <5% blasts were classified as minimal residual disease (MRD) cohort *vs* patients ≥5% blasts as morphologic disease cohort. Response assessment occurred at 4 weeks. Median follow-up duration was 18 months (range, 0.2-57.3).
Results: 51 adults received 19-28z CAR T cells; 20 in the MRD and 31 in the morphologic cohort. Complete remission (CR) rates were comparable (95% and 77%, respectively). However, median event-free and overall survivals widely diverged among the 42 patients who achieved MRD-negative CR: not reached (NR) (95% confidence interval [CI]: 4.2-NR) *vs* 6.3 months (95% CI, 4.8-9.0) (p=0.0005), and NR (95% CI, 15.3-NR) *vs* 17 months (95% CI, 8.5-36.2) (p=0.0189), in the MRD and morphologic cohorts, respectively. Subsequent allogeneic HSCT in either cohort did not improve survival (p=0.8). MRD cohort patients developed substantially less severe cytokine release syndrome (CRS) and neurotoxicity, and both toxicities significnatly correlated with peak

CAR T cell expansion (p=0.0326 and p=0.0001, respectively). No case of cerebral edema was observed.
Summary/Conclusions: Despite comparable initial CR rates regardless of pre-treatment disease burden, durability of 19-28z CAR T cell mediated remissions and survival in adult patients with relapsed B-ALL positively correlated to a low disease burden and do not appear to be enhanced by allogeneic transplant. Our findings strongly support the early incorporation of CD19 CAR therapy before morphologic relapse in B-ALL.

S480

STANDARD-RISK RANDOMIZATION OF PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA IN TRIAL AIEOP-BFM ALL 2000 INDICATES EQUAL OUTCOME WITH REDUCED-INTENSITY DELAYED INTENSIFICATION IN ETV6-RUNX1-POSITIVE PATIENTS

K. Bleckmann[1,*], A. Möricke[1], M. Zimmermann[2], G. Mann[3], M.G. Valsecchi[4], C.R. Bartram[5], A. Biondi[6], R. Panzer-Grümayer[3], R. Beier[7], G. Cario[1], F. Locatelli[8], G. Basso[9], F. Niggli[10], M. Aricò[11], V. Conter[12], M. Schrappe[1]
[1]Department of Pediatrics, University Medical Center Schleswig-Holstein, Campus Kiel, Kiel, [2]Pediatric Hematology/Oncology, Medical School Hannover, Hannover, Germany, [3]CCRI, St. Anna Children's Hospital, Medical University of Vienna, Vienna, Austria, [4]School of Medicine and Surgery, University of Milano Bicocca, Monza, Italy, [5]Institute of Human Genetics, Ruprecht-Karls University, Heidelberg, Germany, [6]M.Tettamanti Research Center, Pediatric Clinic, University of Milan Bicocca, Monza, Italy, [7]Dept. of Pediatric Hematology and Oncology, University Hospital Essen, Essen, Germany, [8]Department of Pediatric Hematology and Oncology, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, [9]Department SDB, University of Padova, Padova, Italy, [10]Pediatric Hematology/Oncology, University Hospital Zürich, Zürich, Switzerland, [11]Azienda Sanitaria Provinciale Ragusa, Ragusa, [12]Department of Pediatrics, University of Milano-Bicocca, Ospedale S. Gerardo, Monza, Italy

Background: *ETV6-RUNX1* fusion is a common genetic aberration in childhood acute lymphoblastic leukemia (ALL) and is associated with good prognosis in the context of contemporary treatment regimens. The required treatment intensity for this well-described biologic subgroup with low risk of relapse is not known so far. In trial AIEOP-BFM ALL 2000, feasibility of reduction of delayed intensification treatment to reduce the burden of chemotherapy was tested in a randomized approach in the standard-risk group. Treatment reduction was not successful in the total cohort (8-year probability of disease-free survival (8y-pDFS, ± standard error) 89.2±1.3% for reduced delayed intensification treatment, 92.3±1.2% for the standard treatment (log-rank *P*=0.04) due to evidence of more relapses observed in patients treated less intensively.
Aims: The retrospective subgroup analysis presented here focuses on the *ETV6-RUNX1*-positive patients included in the group of randomized standard-risk patients.
Methods: From 07/2000 to 06/2006, 4741 eligible patients with ALL (age range 1-17 years) were enrolled in the trial AIEOP-BFM ALL 2000 (NCT 00430118 (BFM) and NCT 00613457 (AIEOP)). Of those, 1164 patients were considered at standard risk of relapse, defined by lack of genetic high-risk criteria and absence of minimal residual disease at day 33 and week 12 of treatment (tested by immunoglobulin/T-cell receptor gene rearrangement polymerase chain reaction). They were randomly assigned to either receive the reduced-intensity protocol III (P-III), or standard protocol II (P-II) for delayed intensification. P-III is shorter than P-II (duration 29 *vs* 49 days), the dose of dexamethasone in P-III is 30% lower, and the dose of vincristine, doxorubicin, and cyclophosphamide are reduced by 50% as compared to P-II. The intention was to prove non-inferiority of the reduced-intensity treatment compared to standard treatment.
Results: *ETV6-RUNX1*-positive patients (n=367) accounted for 34% of randomized standard-risk patients (Age: <6 years n=260, 6 to <10 years n=79, ≥10 years n=28; early cytologic response evaluation in bone marrow on day 15 of induction treatment: M1 n=218, M2 n=74). Of those, 188 were treated with the experimental P III, 179 received the standard P-II. With a median follow-up of 8.6 years, the as-treated analysis showed an 8y-pDFS of 94.5±1.7% for P-III, and 94.4±1.8% for patients with P-II (log-rank *P*=0.74). Cumulative incidence of relapse at 8 years was 3.3±1.3% and 4.3±1.6% (Gray *P*=0.09), and 8-year overall survival was 96.9±1.4% and 98.8±0.9% (*P*=0.27) for P III and P II, respectively. Analysis of *ETV6-RUNX1*-positive patients by age groups or treatment response on day 15 allowed no further refinement of prognostic subgroups.
Summary/Conclusions: There was no evidence of prognostic disadvantage in *ETV6-RUNX1*-positive standard-risk patients when treated with the reduced-intensity experimental arm. No clear age- or response-dependent differences could be revealed for this group, which is in line with the biologic understanding of this genetic subgroup. Hence, it might be postulated that treatment reduction might be feasible in this clearly defined biologic subgroup. However, the present data is not result of a sufficiently powered non-inferiority study question focused on the subgroup of *ETV6-RUNX1*-positive patients, but reflects a subgroup analysis with descriptive character. Therefore, any decision for treatment reduction should be considered carefully.

Biology and disease monitoring in CML

A SECOND GENERATION LYSOSOMOTROPIC AGENT DRIVES LEUKAEMIC STEM CELL DIFFERENTIATION AND SENSITIZES THEM TO TYROSINE KINASE INHIBITOR TREATMENT *IN VITRO* AND *IN VIVO*

P. Baquero[1,*], E. Kuntz[2], R. Mitchell[1], A. Ianniciello[1], K.M. Ryan[2], E. Gottlieb[2], R.K. Amaravadi[3], T.L. Holyoake[4], G.V. Helgason[1]
[1]Wolfson Wohl Cancer Research Centre, Institute of Cancer Science, University of Glasgow, [2]Cancer Research UK, Beatson Institute, Glasgow, United Kingdom, [3]Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States, [4]Paul O'Gorman Leukaemia Research Centre, Institute of Cancer Science, University of Glasgow, Glasgow, United Kingdom

Background: Autophagy is a conserved catabolic process that delivers cytoplasmic constituents to the lysosomes. We have previously shown that the lysosomotropic agent hydroxychloroquine (HCQ) inhibits autophagy and sensitizes Chronic Myeloid Leukaemia (CML) stem cells (LSCs) to tyrosine kinase inhibitors (TKIs) treatment. However, the biological effects of autophagy inhibition in LSCs *in vivo* are currently unknown and remain to be investigated. Furthermore, recent clinical studies showed that maximum tolerated dose of HCQ does not achieve consistent autophagy inhibition in cancer patients. Therefore further pre-clinical studies using more potent 2nd generation lysosomotropic agents, alone and in combination with TKIs, are vital.
Aims: Here we aim to investigate the functional effects of autophagy inhibition in LSCs both *in vitro* and *in vivo* using the highly potent lysosomotropic agent Lys05. Additionally, we aim to address whether Lys05 achieves autophagy inhibition in the most primitive LSC populations *in vivo* and whether it targets LSCs more effectively than HCQ when combined with TKIs.
Methods: In this study, we used primary stem-cell enriched samples ($CD34^+$ cells) derived from CML patients at diagnosis. For *in vivo* studies, we used a human patient-derived xenograft (PDX) model and an inducible transgenic CML model in which the expression of BCR-ABL is induced at a stem/progenitor level (Scl-tTa-BCR-ABL). To accurately measure autophagy flow in long term LSCs *in vivo*, we generated the transgenic mouse Scl-tTa-BCR-ABL/GFP-LC3 by crossing the Scl-tTa-BCR-ABL model with a mouse bearing the autophagy marker LC3 fused to GFP.
Results: Firstly, we show that Lys05 targets LSCs more potently than HCQ *in vitro* by achieving a 60% and a 35% reduction in number of $CD34^+CD38^-$ and $CFSE^{max}/CD34^+CD133^+$cells respectively. Interestingly, Lys05 promoted a 40% loss of quiescent cells and induced myeloid differentiation of $CD34^+$ cells. Functional long-term culture initiating cell (LTC-IC) assay demonstrated that, while HCQ had moderate effects, Lys05 decreased the number of LSC-derived colonies by 80%. Additionally, we show that Lys05 inhibits autophagy flow more efficiently than HCQ both in the Scl-tTa-BCR-ABL/GFP-LC3 model and in patient-derived progenitor cells. Analysis of bone marrow (BM) cells from Lys05-treated leukaemic mice (but not from HCQ-treated mice), showed a statistically significant 35% decrease (p=0.0469) in the most primitive population $Lin^-Sca^+c\text{-}kit^+CD48^-CD150^+$ followed by a 50% increase (p=0.0231) of progenitors $Lin^-Sca^+c\text{-}kit^+$. This result indicates differentiation of LSCs towards a more progenitor phenotype following potent autophagy inhibition. Finally, to test the *in vivo* effect of Lys05 on the most primitive human LSCs we transplanted $CD34^+$ CML cells into irradiated NSG mice. Remarkably, using this PDX model we show that while 3 weeks *in vivo* treatment with HCQ had no effects when combined with TKIs, Lys05 and TKI treatment nearly eliminated engrafted primitive Philadelphia positive $CD34^+CD38^-$ and $CD34^+CD133^+$cells.
Summary/Conclusions: Overall, we demonstrate that lysosomal inhibition induces loss of quiescence and drives differentiation of LSCs *in vitro* and *in vivo*. Furthermore, our results show that Lys05 achieves autophagy inhibition in LSCs and effectively sensitizes LSCs to TKIs *in vitro* and *in vivo*. Therefore, 2nd generation lysosomotropic agents should be considered as a potential alternative to HCQ in order to eliminate LSCs and achieve cure for CML patients.

FC GAMMA RECEPTOR 2B IS CRITICAL FOR BCR-ABL MEDIATED LEUKEMOGENESIS

O. Herrmann[1,*], S. Langer[2], C.C. Wessling[3], M. Huber[4], S. Li[5], T.H. Brümmendorf[1], S. Koschmieder[1], M. Schemionek[1]
[1]Department of Internal Medicine - Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, Faculty of Medicine, University Hospital RWTH Aachen, Aachen, [2]Institute of Transfusion Medicine, University Hospital Essen, Essen, [3]Department of Neurosurgery, University of Bonn, Bonn, [4]Institute of Biochemistry and Molecular Immunology, University Hospital RWTH Aachen, Aachen, Germany, [5]University of Massachusetts Medical School, Worcester, United States

Background: Chronic myeloid leukemia (CML) is provoked by the chromoso-

mal translocation t(9;22) that gives rise to the oncogenic tyrosine kinase Bcr-Abl. Implementation of tyrosine kinase inhibitor (TKI) therapy resulted in significant clinical success but with TKIs failing to eradicate the disease initiating leukemic stem cell population (LSC), this treatment is not curative in the vast majority of patients. By using a transgenic CML mouse model, we previously showed that LSC persist despite complete Bcr-Abl kinase inhibition due to a lack of oncogene-addiction. Subsequently, we identified the ITIM carrying Fc gamma receptor IIb (FcγRIIb; CD32) to be 2.8-fold upregulated in Bcr-Abl$^+$ *versus* control LSK (lin$^-$;Sca-1$^+$;c-kit$^+$) cells using microarray and qRT-PCR.

Aims: In this study, we first aimed to validate Bcr-Abl mediated FcγRIIb upregulation on mRNA and protein level in leukemic cells. Next, we tested the effect of shRNA mediated FcγRIIb knock-down and depletion on CFU (colony forming unit) capacity, proliferation and leukemic signaling *in vitro*. Finally, we studied the disease-initiating potential of primitive CML stem and progenitor cells upon FcγRIIb knock down.

Methods: qRT-PCR and western blot analyses were applied using cell lines, primary murine cells and HoxB8 immortalized murine bone marrow (BM) cells for studying FcγRIIb expression and signaling. In order to test the biology of CML cells *in vitro,* we performed CFU and proliferation assays. Moreover, we performed viral infection of 5-FU treated SCLtTA/Bcr-Abl BM using FcγRIIb:shRNA or scrambled control and subsequent transplantation, followed by analyses of the disease, including immune-phenotyping, RNA and protein expression as well as histological analysis.

Results: Bcr-Abl increased FcγRIIb mRNA (13.2-fold, p≤0.001) and protein expression in primary murine lineage negative (lin$^-$) BM cells. Reduction of FcγRIIb in immortalized SCLtTA/Bcr-Abl progenitor cells significantly reduced CFU potential by nearly 10-fold (p≤0.01) and it impaired the proliferation rate in these cells (2.27-fold, p≤0.001). Moreover, transplantation of SCLtTA/Bcr-Abl-shRNA:FcγRIIb BM cells (CD45.1$^+$) into FVB/N wildtype (WT) CD45.2$^+$ recipients reduced spleen weight (352 ± 59.13mg), as compared to scrambled shRNA (568.1 ± 101.72mg). FACS analysis revealed a decrease in GFP$^+$;CD45.1$^+$ BM cells (1.43-fold, p≤0.001) upon FcγRIIb knock down. Likewise, donor-derived Gr-1$^+$ cells (Gr-1$^+$;CD45.1$^+$;GFP$^+$) were reduced in the BM (1.28-fold, p≤0.01) of these mice. Flow-cytometric analysis of the stem cell compartment revealed decreased leukemic BM LSK cells (lin$^-$, c-kit$^+$, Sca-1$^+$, CD45.1$^+$, GFP$^+$, 1.38-fold, p≤0.05) in mice transplanted with shRNA:FcγRIIb *vs* scrambled control. We previously observed similar effects upon FcγRIIb depletion (FcγRIIb$^{-/-}$) *vs* wildtype (FcγRIIb$^{+/+}$), combined with virally induced Bcr-Abl expression. Interestingly, Bcr-Abl signaling induces FcγRIIb phosphorylation in leukemic cells. Analysis of downstream signal pathways showed decreased levels of p-ERK, p-BTK, p-PLCγ1 in FcγRIIb$^{-/-}$, compared to FcγRIIb$^{+/+}$ Bcr-Abl transduced immortalized primary murine BM cells.

Summary/Conclusions: FcγRIIb is upregulated in LSC derived from transgenic CML mice upon Bcr-Abl expression. Complete depletion or knock down of the receptor reduces CFU capacity and cell growth in CML cells and significantly impairs CML development and LSC burden *in vivo,* presumably due to impaired leukemic downstream signaling. Our data demonstrate that FcγRIIb is critical and disease specific making it a potential novel therapeutic target in CML stem cells.

MYC-DEPENDENT REPRESSION MECHANISM OF THE MIR-150 TRANSCRIPTIONAL REGULATION IN CHRONIC MYELOID LEUKEMIA

P. Burda[1,2], N. Čuřík[1,2,*], K. Šrůtová[1], F. Savvulidi[2], G. Silvestri[3], H. Klamová[1,4], P. Pecherková[1], Ž. Sovová[1], J. Koblihová[1], T. Stopka[5], D. Perrotti[3], K. Machová Poláková[1,4]

Background: The expression of miRNAs is regulated at transcriptional and posttranscriptional levels. Dysregulation of miRNAs could directly induce or be a consequence of oncogenic pathways. Chronic myeloid leukemia (CML) is characterized by reduced miR-150 levels leading to an insufficient repression of its target, oncogene MYB. CML treatment with imatinib normalizes miR-150 levels. Thus miR-150 is crucial for CML biology, however, little is known about its upstream transcriptional regulation. MiR-150 is an inhibitor of oncogene MYB, which is required for BCR-ABL1-dependent leukemogenesis in CML blast crisis. Our recent work brought an evidence of mutual BCR-ABL1/MYC/miR-150/MYB regulatory links in CML, sustained in CML resistant cells. We found low levels of miR-150 to be a hallmark of CML and impaired signaling pathway MYB/BCR-ABL1/MYC/miR-150/miR-155/PU.1 leading to a progressive cell differentiation block.

Aims: To delineate potential mechanisms of the miR-150 transcription regulation via the oncogenic transcription factor MYC in CML.

Methods: Primary bone marrow cells from CML (N=28), CML cell lines K562 and KCL-22 and imatinib resistant (K562R, KCL-22R). Expression analysis: RT-PCR. Protein levels: WB. ChIP: chromatin from the cell lines. SiRNA inhibition: AMAXA electroporation. DNA methylation analysis: Methylated DNA immunoprecipitation.

Results: We observed that unlike MLL-AML diagnosis (Jiang *et al.* 2012), CML is not characterized by a block of miR-150 maturation and that miR-150 levels negatively correlated with MYC mRNA levels in CML HSPCs (p<0.001). Role of MYC in CML was further strengthen by imatinib induced MYC downregulation and restored miR-150 levels in K562 and KCL22. Imatinib resistance in K562R and KCL-22R was characterized by further miR-150 downregulation. To assess the MYC role on regulating miR-150 levels we tested the MYC binding sites upstream the miR-150 gene. We detected MYC binding to the upstream CpG of the MIR150 gene in K562 and KCL-22. We also found a depletion of MYC from the miR-150 locus after the imatinib treatment. We suggested potentially synergistic route for imatinib-induced BCR-ABL1 inhibition. This could be processed not only directly but also through an inhibition of a mutual positive regulatory loop between MYC and BCR-ABL1 (Xie *et al.* 2002). We also noticed MIR150-neighboring gene FCGRT (which is adjacent to the studied miR-150 CpG) to become activated by imatinib. We observed MYC levels dependent regulation of both genes, but FCGRT is activated by MYC. This different MYC regulatory role may be facilitated by the detected transcription factor CTCF binding to an insulator site between miR-150 promoter and the CpG. An activation of the insulator via CTCF binding changes an interaction between enhancers and promoters (Bell *et al.* 2000). CTCF was previously described to be an inhibitor of MYC transcription and we show CTCF transcription to be induced by imatinib. CTCF binding to DNA is prevented by DNA methylation. We did not detect DNA methylation within MIR150 upstream region.

Summary/Conclusions: A miR-150 transcription regulation involves transcription factors-dependent epigenetic changes within the promoter and distal enhancers. We outlined a new insight into MYC/MIR150/BCR-ABL1/imatinib regulation loop in CML. Our work revealed a MYC role in miR-150 repression underlying the CML leukemogenesis, where miR-150 functions as a pivotal gatekeeper and its repression is probably required for CML establishment and is enforced in imatinib resistant CML.

COMPARISON OF GENOMIC DNA AND REVERSE TRANSCRIPTASE Q-PCR FOR THE MONITORING OF FIRST-LINE IMATINIB TREATMENT: AN ALLG CML9 SUB-STUDY

I.S. Pagani[1], P. Dang[1], I.O. Kommers[2], J. Goyne[1], V.A. Saunders[1], J.A. Prime[3], D.L. White[1], S. Branford[3], T.P. Hughes[1], D.M. Ross[4,*]

[1]Cancer Theme, South Australian Health and Medical Research Institute (sahmri), Adelaide, Australia, [2]School of Medicine, Vrije Universiteit Medical Center, Amsterdam, Netherlands, [3]Department of Genetics and Molecular Pathology, Centre for Cancer Biology,SA Pathology, [4]Department of Haematology, Royal Adelaide Hospital and SA Pathology, Adelaide, Australia

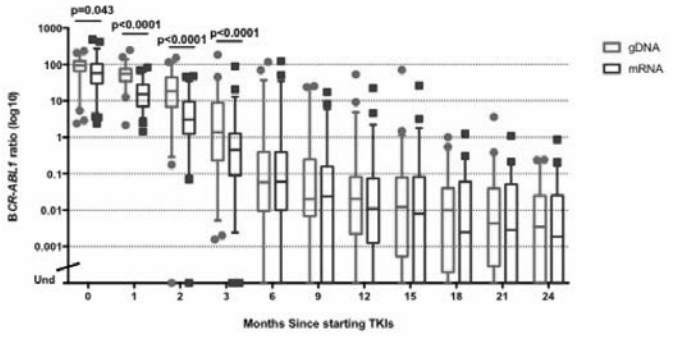
Background: Real-time reverse transcriptase quantitative PCR (RQ-PCR) for *BCR-ABL1* mRNA is widely used for the monitoring of chronic myeloid leukaemia (CML). Pre-analytical factors, such as the rate of degradation of the target mRNA, and methodological factors, such as the choice of control gene, may influence the final result. In contrast the genomic DNA is stable, and the number of copies of *BCR-ABL1* DNA is directly proportional to the number of CML cells. Measuring both DNA and RNA may enable us to understand the contribution of expression and cell number to the RQ-PCR response.

Aims: To compare *BCR-ABL1* DNA Q-PCR and routine RQ-PCR monitoring of CML.

Methods: Fifty-nine newly diagnosed chronic phase CML patients from the ALLG CML9 (TIDEL II) trial were included in this sub-study. Samples were tested prior to commencing TKI treatment (baseline), at 1, 2, and 3 months, and every 3 months to 24 months (total 568 samples). Since we wanted to compare the sensitivity of the Q-PCR methods we selected 19 patients who had achieved undetectable minimal residual disease (UMRD) by RQ-PCR within 24 months, and an additional 40 patients unselected for response. RQ-PCR results were expressed on the International Scale (IS), whereas DNA results were expressed relative to the individual patient's baseline. Quantification of *BCR-ABL1* DNA was performed using *GUSB* as the control gene by real-time Q-PCR (n=40) or by digital PCR (dPCR, n=19) using the Fluidigm BioMark HD System. The mean detection limit of RQ-PCR was 4.5-log, and 5.4-log for DNA methods.

Results: We first demonstrated that DNA dPCR and real-time Q-PCR gave comparable results: 45 samples from 6 patients were quantified by both methods and logarithmically transformed. The mean bias was -0.15 (1.4-fold) with 95% limits of agreement ranging from -1.19 to 0.88. Subsequently, DNA and mRNA values were compared in paired samples. The median *BCR-ABL1*^{IS} at baseline was 58% (range, 2.4% - 487%) *versus* 93% by DNA methods (range, 2.4% - 235%). Interestingly, *BCR-ABL1* DNA was significantly higher than mRNA at 1, 2, and 3 months (Figure). There was good agreement between positive results from 6 months of TKI therapy onwards (mean bias -0.02; 95% limits of agreement from -1.15 to 1.11). Comparing the limit of detection, *BCR-ABL1* DNA was detectable in 60/148 (41%) samples with undetectable mRNA

(median 0.002%, range 0.0003-0.07%). Finally, 88% (15/17) of patients with e14a2 transcripts achieved MMR by 12 months, in comparison with 63% (20/32) of patients with e13a2 transcripts. *BCR-ABL1* mRNA expression levels were significantly lower in e13a2 patients than in e14a2 patients in all follow-up samples analysed (ratio of *BCR-ABL1* mRNA:DNA for e13a2 0.44 *vs* e14a2 0.57; p=0.016).



Comparison of *BCR-ABL1* DNA and mRNA[IS] levels in 59 TKI-treated patients. DNA values in red are expressed as *BCR-ABL1/GUSB* % and compared with *BCR-ABL1/BCR*[IS] %. Und: undetectable.

Figure 1.

Summary/Conclusions: In the first 1-3 months *BCR-ABL1* mRNA fell more rapidly than DNA, likely reflecting the time taken for normal haematopoietic cells to recover. At later time-points there was good agreement between methods, indicating that later reduction in *BCR-ABL1*[IS] is closely related to depletion of leukaemic cells. Normalised to *BCR-ABL1* DNA the expression of e13a2 *BCR-ABL1* mRNA was lower than that of e14a2, an observation that requires confirmation. DNA methods were more sensitive: following the achievement of UMRD by RQ-PCR patients could, on average, be monitored by DNA Q-PCR for an additional 5 months.

Background: Benchtop next generation sequencers are gradually replacing Sanger sequencers in diagnostics labs because of greater throughput, better sensitivity and increasing cost-effectiveness. In chronic myeloid leukemia (CML) patients (pts) on tyrosine kinase inhibitor (TKI) therapy, BCR-ABL1 kinase domain (KD) mutation screening is a precious tool for timely and rational therapeutic reassessment and is recommended in case of Failure and Warning. A multicenter, multilaboratory prospective study ('NEXT-IN-CML') has been conducted to assess the feasibility, cost, turnaround times and clinical utility of a next generation amplicon deep sequencing (Deep Seq) strategy for routine BCR-ABL1 KD mutation screening.

Aims: The first phase of the study was aimed to i) create a network of 4 labs sharing a common protocol, a joint database for clinical and mutational data storage and a common pipeline of data analysis, interpretation and reporting, and ii) verify accuracy and inter-laboratory reproducibility of results. The second phase of the study, involving 39 Italian Hematology Units, was meant to prospectively assess the frequency of low burden mutations in CML pts with Failure or Warning to any TKI.

Methods: In the first phase, centrally prepared identical batches of 32 blinded samples (24 clinical samples with known mutation status/load as assessed by Sanger Seq plus 8 T315I+ BaF3 cell line dilutions simulating mutation loads between 20% and 1%) were distributed and analyzed in parallel by each of the 4 participating labs. In the second phase, 159 consecutive CML pts were prospectively studied in parallel by Sanger Seq and by Deep Seq: 101 Failures (57 pts on 1st-line TKI [IM, n=38; DAS, n=12; NIL, n=7] therapy; 35 pts on 2nd-line TKI [DAS, n=14; NIL, n=17; IM, n=2; BOS, n=1; PON, n=1] therapy; 5 pts on 3rd-line TKI [DAS, n=4; NIL, n=1] therapy and 4 pts on 4th-line TKI [BOS, n=1; PON, n=3] therapy) and 58 Warnings (38 on 1st-line TKI [IM, n=28; DAS, n=4; NIL, n=5; BOS, n=1] therapy and 20 on 2nd-line TKI [NIL, n=10; DAS, n=9; PON, n=1] therapy).

Results: In the first phase, 504/512 amplicons were successfully generated and sequenced, with a median number of forward and reverse reads of 1,757 (range 544-5,838). In the 128 samples analyzed, 51/52 expected mutations were consistently detected by all 4 labs and quantitation of mutation load was highly reproducible across a wide range of frequencies (2%>100%). Three out of 4 labs failed to detect the 1% T315I+ dilution. In clinical samples, additional low burden mutations <3% were occasionally called by one or two labs only, suggesting that this value should be taken as a threshold below which mutation detection is not reproducible and sequencing artifacts and errors cannot be ruled out. In the second phase of the study, pts positive for mutations were 25/159 (16%; 23 Failures and 2 Warnings) by Sanger Seq and 52/159 (33%; 44 Failures and 8 Warnings) by Deep Seq. Among the pts with low burden mutations detectable by Deep Seq, 4 had a T315I; 34 had other known TKI-resistant mutations; 14 had only mutations with unknown clinical significance. Pts positive for mutations by Deep Seq were more frequent in the High and Intermediate Sokal risk group. The number of positive pts and the number of mutations per pt were not significantly higher in those receiving 2nd- or subsequent-line TKI therapy than in those receiving 1st-line TKI therapy. Compound mutations were found only in 2 out of 52 mutated pts (both in blastic phase).

Summary/Conclusions: 1) Results of the 'NEXT-IN-CML', the first prospective study evaluating the routine diagnostic use of Deep Seq of BCR-ABL1, show that this technology can successfully be implemented in national lab networks and is feasible, robust and reproducible; 2) in a relatively large, nonselected cohort of CML pts analyzed for mutations because of a Failure or Warning response, Deep Seq confirmed that enhancing sensitivity enables to detect BCR-ABL1 KD mutations in twice as many pts as compared to Sanger Seq (33% *vs* 16%); 3) all the pts who need to be switched to another TKI would benefit from sensitive BCR-ABL1 KD mutation screening by Deep Seq.

Prognostic markers and new treatment in MDS

S486

PATIENTS WITH IDIOPATHIC CYTOPENIA OF UNDETERMINED SIGNIFICANCE SHOW SIMILAR SURVIVAL PATTERNS AS LOW RISK MDS PATIENTS

J.W. Hansen[1,*], M. Westman[2], A.D. Ørskov[1], L. Sjö[3], L. Saft[4], M.S. Holm[5], C. Claus Marcher[6], M. Karimi[7], E. Hellstrom-Lindberg[7], M.K. Andersen[2], K. Grønbæk[1]

[1]Hematology, [2]Department of Clinical Genetics, [3]Department of Pathology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [4]Department of Pathology, Solna, Karaloniska University, Stockholm, Sweden, [5]Hematology, Aarhus University Hospital, Aarhus, [6]Hematology, Odense University Hospital, Odense, Denmark, [7]Center for Hematology and Regenerative Medicine, Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden

Background: Cytopenia is a hallmark in myelodysplastic syndrome (MDS), however, many patients with persistent cytopenia do not fulfill the criteria for MDS. These patients are now classified as idiopathic cytopenia of undetermined significance (ICUS) or if a mutation is detected as clonal cytopenia of undetermined significance (CCUS). Little is known about these new entities in regards to survival and prognostication.
Aims: In this study we want to compare ICUS patients with MDS patients having low- or very low-risk disease according to the IPSS-R. We also wanted to investigate if sequencing of the cohort could bring additional information in regards to overall survival.
Methods: All patients underwent a bone marrow biopsy, cytogenetics and a broad range of blood tests. Furthermore, all ICUS patients underwent a blinded morphology review by two experienced pathologists; these review data will be ready for presentation at EHA. ICUS was defined as persistent cytopenia for more than six months, no chromosomal aberrations and common causes of cytopenia were ruled out. The patients were sequenced with a targeted sequencing panel, either using a customized Haloplex panel or a customized sequencing panel for the Ion Torrent platform. We analyzed 20 genes which are the most commonly mutated genes in MDS.
Results: So far we included 157 patients, 122 were classified as ICUS and 35 as MDS and the median age is 65 and 68 years, respectively (p=0.27). We have sequenced 78% of the ICUS patients and 74% of the MDS patients. In total 53% and 73% of the ICUS and MDS patients had at least one mutation detected, respectively. If the patients carried a mutation, the median number of mutations was two in both the CCUS and the MDS group. The most commonly mutated genes were *TET2*, *SRSF2*, *DNMT3A* and *ASXL1* in 38 patients (31%), n=16 (13%), n=10 (8%), n=10 (8%), respectively. There were no significant differences in the distribution between the two groups. Mutations in *NRAS*, *KRAS*, *TP53* were only identified in one patient each. The overall survival between the ICUS and the low-risk MDS patients did not differ (p=0.18) (figure 1). We also subdivided the ICUS patients into non-clonal ICUS and CCUS, but observed no difference between these two groups (p=0.355).
Eight of the patients categorized as ICUS progressed to a myeloid neoplasm during the follow up, and of these seven had a detectable mutation at time of enrollment, only one ICUS patient without a detectable mutation progressed (p=0.06).

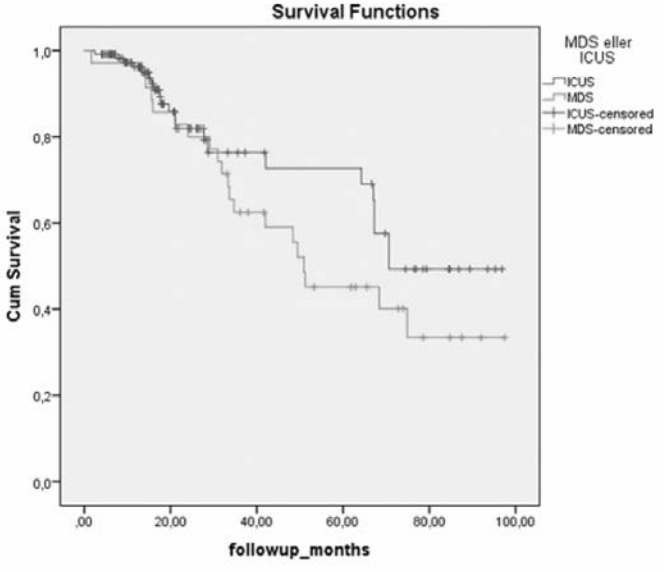

Figure 1.

Summary/Conclusions: We here demonstrate that low-risk MDS and ICUS patients share similar survival patterns, however, larger studies with longer follow up are needed. Mutations are most commonly found in the epigenetic regulators in this cohort of ICUS and low-risk MDS, while mutations in classical tumor suppressors and oncogenes such as *TP53* and *NRAS* are rare. Mutational screening seems promising in detecting patients at risk of progression, however, other biomarkers for prognostication are warranted.

S487

AN UPDATE OF A PHASE II STUDY OF NIVOLUMAB (NIVO) OR IPILIMUMAB (IPI) WITH AZACITIDINE IN PTS WITH PREVIOUSLY TREATED OR UNTREATED MYELODYSPLASTIC SYNDROMES (MDS)

[1]Leukemia, [2]Biostatistics, [3]Hematophatology, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Outcomes of pts with MDS after hypomethylating agent (HMA) failure remain poor. Upregulation of PD-1, PD-L1 and CTLA-4 in MDS CD34+ cells after exposure and loss of response to HMA have been reported. Nivo and Ipi are monoclonal antibodies targeting PD-1 and CTLA-4, respectively, with clinical activity in solid tumors.
Aims: To evaluate the potential activity of immune checkpoint antibodies in patients with previously treated or untreated MDS.
Methods: We designed a phase II study of Nivo or Ipi in monotherapy or combination for pts with MDS. Pts with prior therapy with HMA were to be treated in one of 3 consecutive cohorts: cohort #1: Nivo 3mg/kg iv days 1 and 15 of a 28 day cycle; cohort #2: Ipi 3mg/kg iv on day 1 of a 21 day cycle; cohort #3: Nivo 3mg/kg iv on days 1 and 15 + Ipi 3mg/kg iv on day 1 of a 28 day cycle. The study design allowed for AZA add-back after 6 cycles of therapy if there was no response or progression. Pts with previously untreated MDS were to be treated in one of 3 consecutive cohorts combining AZA 75mg/m^2 iv daily days 1-5 of a 28 day cycle with: cohort #4: Nivo 3mg/kg iv Days 6 and 20; cohort #5: Ipi 3mg/kg iv on day 6; and cohort #6: Nivo 3mg/kg iv on days 6 and 20 + Ipi 3mg/kg iv on day 6. The maximum size per cohort is 20 pts. The primary endpoint is to determine the safety of Nivo or Ipi as single agents or in combination with AZA. Secondary objectives included overall response rate (ORR) and assessment of biological activity. Responses were evaluated following the revised 2006 IWG criteria. The study included stopping rules for response and toxicity.
Results: A total of 63 pts have been enrolled, 54 (86%) are evaluable for response and toxicity including 21 treated with frontline AZA+Nivo, and 15 and 18 with Nivo or Ipi after HMA failure, respectively Median age is 69 years (range 39-85). The median number of treatment cycles was 3 (range 1-11). A total of 3 (27%) pts in the AZA+Nivo cohort, 6 (40%) in the Nivo cohort, and 3 (33%) in the Ipi cohort having related grade ≥3 non-hematologic AEs. Therefore, the stopping rule for toxicity was not met in any of the cohorts. Delays of therapy due to AEs were required in 9 pts due to: rash (N=1), adrenal insufficiency (N=1), colitis (N=1), thyroiditis (N=2), pneumonitis (N=3), and nephritis (N=1). Early 8-week mortality occurred in 1 patient due to a non-related intracranial hemorrhage. The ORR was 80% (13/21) in the AZA+Nivo cohort including 6 CR. The ORR was 0% and 30% (5/18) in the Nivo and Ipi arms, respectively. Therefore, the stopping rule for response was met on the Nivo arm, and enrollment after patient 15 was stopped. Immunophenotypic analysis of stem cell and progenitor compartments was performed in 27 pts, including PD-1 and PD-L1 expression analysis in 16 pts. Increased PD-1 and PD-L1 expression on progenitor and stem cell compartments was observed in 3 and 4 pts, respectively. Treatment with PD-1 inhibitors could not overcome the aberrant differentiation patterns. No differences in response were observed based on PD-1 bone marrow expression.
Summary/Conclusions: Preliminary results indicate that PD-1 blockade with Nivo in combination with AZA in untreated higher-risk MDS pts is associated with a tolerable safety profile and clinical activity. Single-agent Ipi is capable of inducing responses in previously treated MDS pts. Single-agent Nivo did not show clinical activity.

S488

ORAL RIGOSERTIB COMBINED WITH AZACITIDINE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) AND MYELODYSPLASTIC SYNDROMES (MDS): EFFECTS IN TREATMENT NAÏVE AND RELAPSED/REFRACTORY PATIENTS

S. Navada[1,*], G. Garcia-Manero[2], K. Hearn[2], R. Odchimar-Reissig[1], E. Demakos[1], P. Fenaux[3], M. Petrone[4], P. Zbyszewski[4], S. Fruchtman[4], L. Silverman[1]

[1]Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, [2]MD Anderson Cancer Center, Houston, United States, [3]Hôpital Saint-Louis University, Paris, France, [4]Onconova Therapeutics, Newtown, United States

Background: Azacitidine (AZA) is first line therapy for patients (pts) with higher risk MDS and demonstrated efficacy in older pts with AML (Dombret et al, Blood

2015; Fenaux et al, J Clin Oncol 2010). Rigosertib (RIG) interferes with the RAS-binding domains of RAF kinases and inhibits the RAS-RAF-MEK and the PI3Ks pathways. In vitro, the combination of RIG with AZA synergistically inhibits growth and induces apoptosis of leukemic cells in a sequence-dependent manner (Skidan et al, AACR 2006). RIG's effective inhibition of human hematopoietic tumor cell lines in vitro, favorable clinical adverse event (AE) profile, and its synergy with AZA suggests the potential value of combination treatment.

Aims: Phase I/II results are presented for pts with MDS, either hypomethylating (HMA) treatment naïve or progressing on or failing to respond to prior HMA, and those with AML (per WHO 2002 criteria) with relapsed or refractory disease.

Methods: Oral RIG was administered twice daily on Day 1-21 of a 28-day cycle in escalating cohorts and then at the recommended Phase II dose (560mg qAM and 280mg qPM). AZA 75mg/m^2/d SC or IV was administered for 7 days starting on Day 8. A CBC was performed weekly, and a bone marrow aspirate/biopsy were performed at baseline, D29, and then every 8 weeks thereafter. Response was determined by IWG criteria for MDS (2006) and AML (2003). Stable disease in AML was defined as not meeting criteria for any other treatment response (CR, CRi, PR, disease progression, or treatment failure).

Results: The combination of oral RIG and AZA was administered to 54 pts, of whom 40 had MDS; HMA-treatment-naïve (N=23) and previously HMA-failed pts (N=17). 17 MDS pts received prior HMA therapy: 12 AZA, 4 decitabine, and 1 both. Ten pts had AML, and 6 had CMML. 2 MDS patients with 20-<30% marrow blasts were also included in the AML analysis. Median age was 68 years; 67% of pts were male; and ECOG performance status was 0-1 in 95% of pts. Pts have received 1-37+ cycles of treatment (median, 3.5 cycles), with a median duration of treatment of 17 weeks (range 4 to 158+ weeks). Of the 10 pts with AML, 6 had relapsed AML, 2 secondary AML and 2 with AML transformed from MDS. Eight pts were evaluable for response. There were 3 responses seen, for an ORR of 37.5%, with responses in both secondary and refractory AML. Two additional pts had stable disease (25%). Responses were durable, with the longest response approaching one year (Table 1). Among 33 evaluable MDS pts, overall response by IWG criteria was 76%: complete remission (CR) in 8 (24%), concurrent marrow CR (mCR) and hematologic improvement (HI) in 10 (30%), mCR alone in 6 (18%), and HI alone in 1 (3%). Overall response was 85% in HMA naïve pts and 62% in HMA resistant pts. Correlative studies suggest that RIG has chromatin modifying effects in combination with AZA which may overcome clinical AZA resistance (Chaurasia EHA 2017). Median duration of CR was 8 months for the combination. Median time to initial response was 2 cycles, and median time to best response was 3 cycles. The most frequently reported AEs were diarrhea (70%), nausea (50%), back pain (40%), constipation (40%), fatigue (40%), and peripheral edema (40%).

Table 1.

UPN	Age (years)	Cohort*	DoT (weeks)	Previous Therapy	Status at Study Entry	IWG Response (DoR - weeks)	Reason for Discontinuation
101-003	61	140 bid	4.0	1. Induction 2. Investigational	AML - Refractory	NE	Patient request
101-002	70	140 bid	29.6	Growth Factors	AML - Secondary	MoCR (25.3)	Progressive Disease
102-001	76	140 bid	4.0	Growth Factors	MDS/AML	NE	Toxicity/AE
102-003	78	140 bid	55.1	Growth Factors	MDS/AML	MoCR (43)	Progressive Disease
101-005	73	280 bid	4.0	1. Induction 2. DEC x5	AML – 1st Relapse	TF/I	Death
102-009	71	560/280	12.9	1. Induction x2 2. AZA x25	AML - Relapsed	TF/R	Death
102-007	80	560/280	32.0	AZA x5	AML - Secondary	TF/R	No Hem Response
101-008	57	560/280	8.1	Induction	AML - Refractory	MLFS (4.1)	Inv. Decision
101-009	60	560/280	24.4	Induction	AML - Relapsed	SD	Death
101-007	77	560/280	16.0	1. Induction 2. DEC x12	AML - Relapsed	SD	Progressive Disease

MDS/AML – 20 to <30% blasts
NE – patients off study prior to 12 weeks of combination
MoCR – morphologic complete remission
TF/I – treatment failure/indeterminate
TF/R – treatment failure/resistant
MLFS – morphologic leukemia-free state
SD – stable disease
* Oral rigosertib dose

Summary/Conclusions: The combination of oral RIG and standard-dose AZA was well tolerated in repetitive cycles in pts with AML and MDS. Response was observed both in HMA-treatment-naïve pts (85%) and in pts failing HMA therapy (62%), suggesting the addition of RIG can overcome HMA clinical resistance by acting as a chromatin modifying agent. In AML, responses were seen in 37.5% of evaluable pts. Based on these results, continued study in AML is warranted. A Phase III study of the combination of oral RIG and AZA in pts with treatment naïve MDS is planned.

S489

IMPACT OF THE MUTATIONAL PROFILE AT THE TIME OF DIAGNOSIS IN RESPONSE OUTCOMES IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND CHRONIC MYELOMONOCYTIC LEUKEMIA TREATED WITH HYPOMETHYLATING AGENTS

G. Montalban-Bravo[1,*], A. Alfonso[1], K. Patel[2], E. Jabbour[1], C. Benton[1], T. Kadia[1], F. Ravandi[1], J. Cortes[1], C. DiNardo[1], N. Daver[1], G. Borthakur[1], N. Pemmaraju[1], M. Konopleva[1], I. Ganan-Gomez[1], G. Nogueras-Gonzalez[3], X. Huang[3], F. Wang[4], S. Xingzhi[4], C. Bueso-Ramos[2], A. Futreal[4], H. Kantarjian[1], K. Takahashi[1], G. Garcia-Manero[1]
[1]Leukemia, [2]Hematophatology, [3]Biostatistics, [4]Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Hypomethylating agents (HMA) such as azacitidine and decitabine remain the standard of care for the treatment of myelodysplastic syndromes (MDS) however, loss of response to therapy is associated with poor outcomes. Multiple studies have tried do identify biomarkers of response but the impact of the mutational architecture present at the time of diagnosis in response outcomes is unclear.

Aims: To evaluate the impact of the mutational architecture present at the time of diagnosis in response outcomes is unclear.

Methods: We evaluated 222 previously untreated patients with MDS or CMML that received HMA therapy at The University of Texas MD Anderson Cancer Center. Next generation sequencing analyzing a panel of 28 genes was performed prior to therapy with HMA. VAF estimates were used to evaluate clonal and subclonal relationships within each individual sample with clonal heterogeneity being defined in cases with Pearson goodness-of-fit p-values <0.05. Generalized linear models were used to study association of response rates (ORR=overall and CR=complete) and risk factors. Response was defined following 2006 IWG criteria.

Results: A total of 143 patients (79%) had MDS and 43 (19%) had CMML, including 108 (49%) with lower-risk based on IPSS and 114 (51%) with higher-risk disease. Therapy consisted in azacitidine monotherapy in 60 (27%) patients, decitabine monotherapy in 57 (26%), guadecitabine in 46 (21) and combinations in 59 (27%). The ORR was 61% (135/222) with 80 (36%) patients achieving CR. A total of 161 (73%) patients had at least one detectable mutation. Median number of mutations was 1 (range 0-5). Frequencies of detected mutations are shown in Figure 1A. Among 70 (32%) patients evaluable for clonal heterogeneity testing, 38 (55%) where clonally heterogeneous and carried at least 1 subclone. Pairwise associations of mutations revealed distinct and significant co-mutation patterns (Figure 1B). Within these co-mutation associations, there were no clear hierarchical patterns of clonality in patients evaluable for clonal heterogeneity, as indicated in Figure 1B. By univariate analysis, presence of mutations in *ASXL1* (OR 0.45, CI 0.22-0.93, p=0.03) and *RUNX1* (0.44, CI 0.20-0.96, p=0.038) as well as that of *TP53* mutations with VAF ≥0.31 (OR 0.21, CI 0.05-0.8, p=0.024) predicted for a lower likelihood of response. Analysis of functional pathways revealed that patients with mutations in chromatin (OR 0.43, CI 0.21-0.86, p=0.017) and signaling genes (OR 0.48, CI 0.23-1.00, p=0.049) had lower likelihood of achieving response. Additionally, patients with *ASXL1* mutations (OR 0.24, CI 0.09-0.64, p=0.005), particularly in the absence of co-occurring *TET2*, as well as those with increased number of mutations, particularly if more than 3 (OR 0.21, CI 0.06-0.73, p=0.014), or signaling gene mutations (OR 0.32, CI 0.13-0.80, p=0.015), had a lower likelihood of achieving a CR. A longer time to response was observed in patients with *DNMT3A* mutations with VAF ≥0.35 (3.4 *vs* 1 months, OR 0.22, CI 0.06-0.76, p=0.017). Among patients who achieved CR, presence of 3 or more mutations (2.6 *vs* 1.3 months, OR 1.35, CI 1.00-1.83, p=0.049) and *TP53* mutations with VAF ≥0.31 (0 *vs* 3.7 months, OR 2.03, CI 1.03-3.98, p=0.040) predicted for shorter CR duration. Presence of clonal heterogeneity, as well as the identified pairwise co-mutation patterns did not predict for any of the response outcomes.

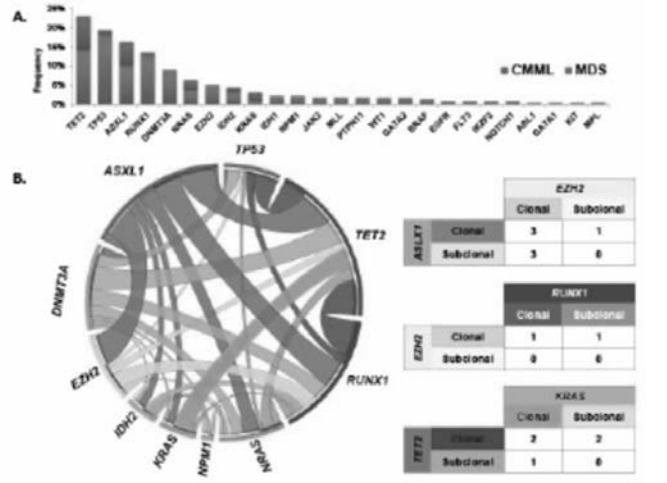

Figure 1.

Summary/Conclusions: The type, number and burden of mutations at the time of diagnosis may predict response to therapy with HMA in patients with MDS and CMML.

STUDY OF THE EFFECT OF MIRNAS TARGETING RPS14 ON CELLULAR BIOLOGICAL BEHAVIOR OF MYELODYSPLASTIC SYNDROMES

Y. Nie[1,*], B. Xiong[1], X. Zuo[1], S. Wang[2]
[1]Zhongnan Hospital of Wuhan University, Wuhan, [2]Institute of Hematology & Blood Disease Hospital, CAMS & PUMC, Tianjin, China

Background: As key factors in gene post-transcriptional regulation, microRNAs(miRNAs) have been identified to play important roles in carcinogenesis in various tumors. Myelodysplastic syndrome(MDS) is a group of clonal myeloid disorders characterized by refractory quantitative and qualitative abnormalities of hemocytes and its pathogenesis is poorly understood. Some studies have showed that abnormal expressions of some miRNAs have close relationship with the pathogenesis of MDS. Recently, low RPS14 expression is found common in all kinds of myelodysplastic syndromes including patients without 5q deletion, but its mechanism remains unclear.
Aims: To determine the cause of RPS14 reduction in MDS except 5q- syndrome, influence of miRNAs on RPS14 expression was analyzed, and the role of specific miRNA on proliferation, differentiation and apoptosis of hematopoietic stem cells were evaluated. This research will help reveal the pathogenesis of MDS from a new angle and provide new ideas for the diagnosis, treatment and prognosis evaluation of MDS.
Methods: Firstly, we predicted that miR-223 may target 3'UTR of RPS14 by bioinformatics software, then verified if the special miRNA could target RPS14 by assay of luciferase activity. Secondly, the mRNA expression level of miR223 were detected in the bone marrow BM selected from 28 MDS patients including ten RCUD patients, ten RCMD patients, four RAEB-1 patients and four RAEB-2 patients, meanwhile, the miR223 expression status were tested in four kinds cell lines including SKM-1, HL-60,K562 and THP-1 cell lines through qRT-PCR and RPS14 expression was detected by means of immunofluorescence(IF). Thirdly, constructing lentivirus which carried miR223 overexpression vector and inhibitor were infected to the SKM-1 cell line and k562 cell line which had the highest level of RPS14, then apoptotic analysis was detected by flow cytometry method and proliferation was tested by CCK-8 assay. Fourthly, hemin (50μM,) was used to induce erythroid differentiation of K562 cells which carried miR223 overexpression We used flow cytometry method CD71 and CD235a makers and qRT-PCR(CD235 and r-globin) to detect the erythroid proliferation.
Results: 1.We verified miR223 could target RPS14 by assay of luciferase activity. 2.MDS patients had higher miR-223 expression compared with health controls especially the types of RAEB-1 and RAEB-2 (P□0.05). In MDS patients, RAEB patients expressed higher level of miR223 than other types of MDS.Meanwhile, in cell lines, K562 cell line showed the highest level of RPS14 and lowest level of miR223. 3. Infecting miR223 overexpression lentivirus could promote cell proliferation and inhibit cell apoptosis while infecting miR223 inhibitor lentivirus had the opposite effect in SKM-1 and K562 cell lines. 4. We found that forced expression of miR-223 suppresses commitment of r-globin, CD235a and CD71 labeling, in contrast, underexpression of miR-223 promoted terminal erythropoiesis in K562 cell line.

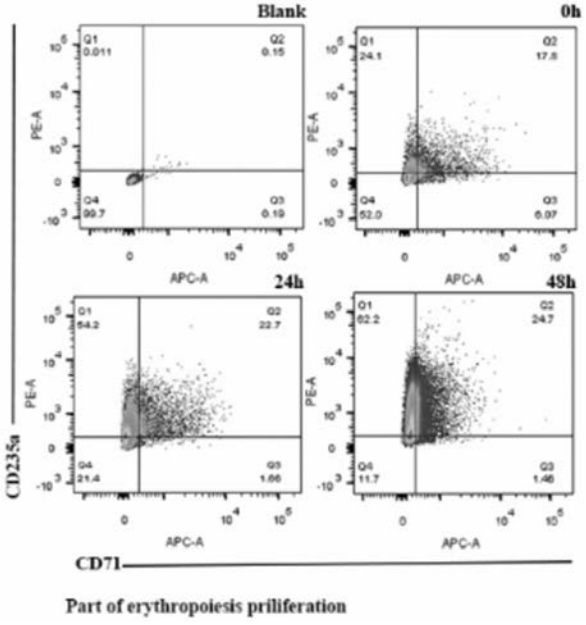

Figure 1.

Summary/Conclusions: MDS patients had higher miR-223 expression compared with health controls. We demonstrated that miR223 could promote cell proliferation, inhibit cell apoptosis and suppress terminal erythropoiesis through target RPS14.

Stem cell transplantation - Clinical 1

Rogers Sr. Department of Electrical and Computer Engineering, University of Toronto, Toronto, Canada, [6]Genomic Research Center for Hematopoietic Diseases, [7]Department of Laboratory Medicine, [8]Department of Pediatrics, Chonnam National University Hwasun Hospital, Hwasun, [9]Department of Hematology-Oncology, Soon Chun Hyang University Hospital, Bucheon, [10]Department of Laboratory Medicine, Samsung Medical Center, [11]Department of Laboratory Medicine, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of, [12]Department of Molecular Genetics, [13]Princess Margaret Cancer Centre/University Health Network, University of Toronto, Toronto, Canada

Background: Clinical applications of next generation sequencing (NGS) in allogeneic hematopoietic stem cell transplantation are a topic of interest. Mutation dynamics post-HCT using longitudinal NGS have not been thoroughly examined. We hypothesized that serial sequencing of pre-HCT and post-HCT in AML patients could provide a much deeper and broader understanding of clonal origin/hierarchy of relapse after allogeneic HCT. The present study aimed to evaluate mutation dynamics in AML using serial samples from pre- and post-HCT with respect to transplant outcomes, particularly overall survival (OS) and relapse.
Aims: To track origins of post-HCT relapse in AML using serial sequencing
Methods: 88 AML patients were enrolled and sequenced using an Illumina HiSeq 2000 sequencer (84 myeloid custom gene panel) on 419 bone marrow samples at diagnosis (n=88), pre-HCT (n=88), 21 days after HCT (n=88), and at relapse (n=20). Two patients relapsed by day 21. T-cell (n=80) and donor samples (n=57) were also sequenced. All computational and statistical analyses were performed using Python and R.

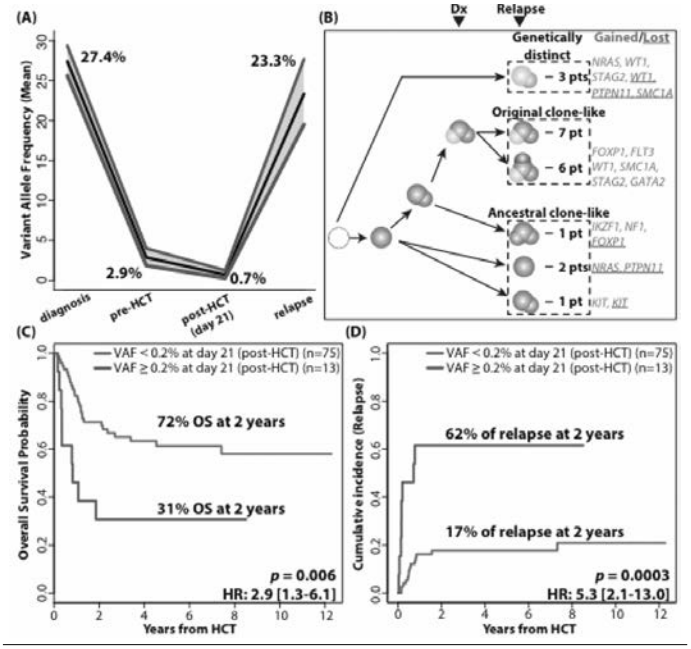

Figure 1.

Results: The mean on-target coverage in 419 samples was 1773.7x. In total, we detected 217 mutations throughout the course of treatment in 79/88 patients (89.8%). *NPM1 (26.1%)*, *DNMT3A (26.1%)*, *CEBPA (13.6%)*, *IDH2 (13.6%)*, *FLT3 (12.5%)*, and *PTPN11 (11.4%)* were commonly mutated at diagnosis. Unsurprisingly, most mutations appeared at initial diagnosis (200/217, 92.1%). Only 1, 2, and 14 mutations were acquired/selected at pre-HCT (0.5%), day 21 (0.9%), and relapse (6.5%), respectively. Most mutations were cleared at pre-HCT (mean mutation allele frequency (VAF) from 27.4% to 2.9%) and were further reduced after HCT (mean VAF from 2.9% to 0.7%) **(Fig A)**. Leveraging

serial samples, we inferred the clonal relationships between original and relapse samples in 20 patients **(Fig B)**. Mutations from initial diagnosis re-appeared in 17 patients. The relapse clone of 13 patients was identical to or clonally evolved from the initial AML clone (7 and 6 patients, respectively). Relapse clones of 4 patients evolved from an inferred ancestral clone, distinct from the initial AML clone. The remaining 3 patients' relapse clones appear to be genetically distinct from the initial AML clone **(Fig B)**. Among 61 mutations from relapsed patients, 37 were stable, whereas 9 were cleared and 15 acquired (or selected) at relapse. Overall, serial samples and donor samples de-convoluted origins of relapse clone from all 20 patients. Among the 13 patients whose donor samples were sequenced, no mutation that was transferred from donor to recipient expanded at relapse. We then assessed whether the mutation status at pre- and post-HCT has any impact on OS and relapse after HCT. With a follow-up duration of 6.9 years, patients with VAF ≥0.2% at day 21 in any gene showed worse OS (HR 2.9, p=0.006) as well as increased risk of relapse (HR 5.3, p=0.0003) **(Fig C-D).** Multivariate analyses verified that VAF ≥0.2% at day 21 was a prognostic factor independent of age and cytogenetics risk group for OS (HR 3.2, p=0.003). Non-relapse mortality did not show significant difference (p=0.3). Thirteen patients carried 20 mutations at day 21 (≥0.2%), 16 of which originated from the initial AML clone. Noticeably, 9 of these mutations (from 9 patients) were in *DNMT3A*, where one of them was a transferred mutation from the donor through HCT (donor VAF: 8.18%, VAF at day 21: 3.42%, non-relapse case). Mutation status at any other time points in any gene, defined with a hard cut-off (VAF >2%), was neither significantly associated with overall survival nor relapse incidence after HCT.

Summary/Conclusions: This study revealed origins of mutations detected at post-HCT relapse. It also revealed that the presence of mutations immediately after HCT, within 21 days, with low VAF (0.2%) can be used to predict relapse after HCT, illustrating the value of longitudinal NGS-based monitoring strategies for AML patients after allogeneic HCT.

IBRUTINIB FOR CHRONIC GRAFT-VERSUS-HOST DISEASE AFTER FAILURE OF FRONTLINE CORTICOSTEROIDS: RESULTS OF A MULTICENTER OPEN-LABEL PHASE 2 STUDY

I. Pusic[1,*], D. Miklos[2], C. Cutler[3], M. Arora[4], E. Waller[5], M. Jagasia[6], M. Flowers[7], A. Logan[8], R. Nakamura[9], B. Blazar[4], Y. Li[10], I. Lal[10], J. Dubovsky[10], D. James[10], L. Styles[10], S. Jaglowski[11]

[1]Division of Oncology, Washington University School of Medicine, St. Louis, [2]Stanford University, Stanford, [3]Dana Farber Cancer Institute, Boston, [4]University of Minnesota, Minneapolis, [5]Winship Cancer Institute of Emory University, Atlanta, [6]Vanderbilt-Ingram Cancer Center, Nashville, [7]Fred Hutchinson Cancer Research Center, Seattle, [8]University of California San Francisco, San Francisco, [9]City of Hope, Duarte, [10]Pharmacyclics, LLC, an AbbVie Company, Sunnyvale, [11]Ohio State University, Columbus, United States

Background: There are no approved therapies for chronic GVHD (cGVHD) after failure of steroids. Both B and T cells play a role in the pathophysiology of cGVHD. In preclinical models, ibrutinib (ibr) reduced the severity of cGVHD through inhibition of Bruton's tyrosine kinase (BTK) and interleukin-2–inducible T-cell kinase (ITK).

Aims: This phase 2 study evaluated the efficacy and safety of ibr in patients (pts) with steroid dependent/refractory cGVHD in need of additional therapy.

Methods: Eligible pts had ≤3 prior regimens for cGVHD and either >25% body surface area erythematous rash or a NIH mouth score >4. Informed consent was obtained from all pts. Pts were treated with ibr 420mg/d until cGVHD progression or unacceptable toxicity. The primary end point was cGVHD response based on 2005 NIH consensus response criteria. Secondary end points included rate of sustained response, change in Lee cGVHD symptom scale, change in steroid dose over time, and safety. The pharmacodynamics (PD) of ibr and its effects on biomarkers associated with GHVD, inflammation, and fibrosis were evaluated.

Results: A recommended phase 2 dose of 420mg was identified in phase 1b (n=6). For 42 pts in phase 2, the median number of prior cGVHD regimens was 2 (range, 1–3). At a median follow-up of 13.9 mo, overall response rate (ORR) was 67% (CR, 21%), with 71% of responders showing a sustained response of ≥20 weeks; 79% responded by the first response assessment. Median steroid dose decreased in responders from 0.29mg/kg/d at baseline to 0.12mg/kg/d at week 49. Overall, 62% of pts achieved steroid doses <0.15mg/kg/d while on ibr; 5 responders discontinued steroids. Organs with cGVHD involvement including skin, mouth, and gastrointestinal system showed similar responses (~90%). Of 25 responders with ≥2 involved organs, 20 (80%) showed a response in ≥2 organs. Improvement in Lee cGVHD symptom score was reported for 43% of responders by month 6 and 61% overall, compared with 11% of nonresponders by month 6 and overall. Ibr blocked BTK-driven basophil activation in an ex vivo IgE stimulation assay and ITK-mediated activation of PLCγ1-Y783 in CD4 T-cells. Analysis of soluble plasma factors associated with inflammation, fibrosis, and cGVHD from all treated pts showed a significant decrease over time with ibr. Adverse events (AEs) were largely grade 1 or 2 events; AEs occurring in ≥20% of pts were fatigue, diarrhea, muscle spasms, nausea, and bruising. Grade ≥3 AEs occurring in ≥10% of pts were pneumonia, fatigue, and diarrhea. Serious AEs (SAEs) occurred in 52% of pts; grade ≥3 SAEs were reported in 40% of pts and included pneumonia, septic shock, and pyrexia. Two fatal events (multilobular pneumonia and bronchopulmonary aspergillosis) were reported. Fourteen pts discontinued ibr for AEs, 5 pts for progressive cGVHD, and 2 pts after resolution of cGVHD symptoms; 29% continued ibr.

Summary/Conclusions: With an ORR of 67% and a sustained response rate of ≥20 weeks of 71%, treatment with ibr resulted in clinically meaningful and durable responses in pts who failed at least 1 prior treatment for cGVHD. Most responders were able to reduce steroid dose. PD and biomarker changes support a beneficial effect of ibr on immune cell subsets in pts with cGVHD. The safety profile was consistent with those previously reported for pts with B cell malignancies and those seen in cGVHD pts on concomitant steroids. Responses in this pretreated, high-risk population support study of ibr for frontline treatment of cGVHD.

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is the standard of care for patients (pts) with intermediate (int-AML) or high-risk AML. In pts lacking matched sibling (MSD), HSCT from haploidentical donors (HAPLO) is an emerging option

Aims: The aim of the study was to compare outcomes of non T cell-depleted HAPLO HSCT to those from MSD

Methods: Included were adults with AML in first CR undergoing transplantation from HAPLO *vs* MSD from 2007-2015. Due to significant interaction between karyotype and donor type, int- and high-risk AML were studied separately. In addition because of some characteristic differences between the 2 groups the propensity score technique was used: 2 MSD were matched with each haplo. The following factors were included in the propensity score model: patient, year of HSCT, time from diagnosis to HSCT, conditioning (RIC), source of stem cells (BM/PB), cytogenetic group, patient and donor CMV serology status

Results: We identified 2654 pts (HAPLO=185; MSD=2469) for int-AML (HAPLO=122; MSD=1888) or high risk-AML (HAPLO=63; MSD=581). Median follow up was 30 (1-116) months. Median age at HSCT was 50 (18-74)years. Among HAPLO recipients, 74% received PTCY and 26% ATG. Conditioning regimen was myeloablative in 50% *vs* 52% (p=0.52) of HAPLO and MSD pts, respectively. HAPLO pts had a longer interval from diagnosis to HSCT (6 *vs* 4 months; p<0.01), had more often high risk-AML (34% *vs* 23%; p<0.01), bone marrow as stem cell source (49% *vs* 19%; p<0.01) and CMV positive donors (72% *vs* 61%; p<0.01). Graft failure occurred more frequently after HAPLO (3% *vs* 1%; p=0.002).For pts with int-AML CI of aGVHD and cGVHD was 29% *vs* 20% (p<0.03) and 30% *vs* 36% (p<0.02) in HAPLO and MSD pts, respectively. At two years, NRM and RI were 26% *vs* 10% (p<0.01) and 17% *vs* 20% (p=0.52) while LFS and OS were 56% *vs* 70% (p<0.01) and 68% *vs* 79% (p<0.01) in HAPLO and MSD pts, and GRFS was 45% *vs* 53% (p<0.05), respectively. In multivariate analysis HAPLO was associated with reduced LFS (HR 1.74; 95% CI 1.30-2.33; p<0.01), OS (HR 1.80; 95% CI 1.32-2.45; p<0.01) and GRFS (HR 1.32; 95% CI 1.01-1.72; p<0.05) and higher NRM (HR 3.03; 95% CI 1.98-4.62; p<0.01). Incremental age was independently associated to lower LFS, OS, GRFS and higher NRM and cGVHD. MAC was associated with lower RI and higher GVHD. A female donor into male recipient was associated to higher GHVD and lower GRFS. A longer interval from diagnosis to HSCT was asso-

ciated to lower LFS. Donor CMV seropositivity was associated with lower GRFS and higher NRM and aGVHD. In high risk-AML aGVHD and cGVHD were 36% *vs* 24% (p=0.03) and 39% *vs* 33% (p=0.80) for HAPLO and MSD pts, respectively. At two years, NRM and RI were 18% *vs* 10% (p=0.16) and 21% *vs* 36% (p<0.02) while LFS and OS were 61% *vs* 55% (p=0.14) and 67% *vs* 66% (p=0.26) in HAPLO and MSD pts; GRFS was 49% *vs* 40% (p=0.17). In multivariate analysis risk of grade II-IV aGVHD (HR: 2.20; 95% CI: 1.29-3.74; p<0.01) was increased after Haplo as compared to MSD and no difference was observed in LFS, OS and GRFS, respectively. Conditioning regimen was associated with lower NRM and higher GRFS, while younger age and donor CMV status were associated with lower RI, higher LFS and OS. Results were confirmed in the analysis done with the the propensity score technique as for RI, NRM, LFS, OS and GRFS

Summary/Conclusions: As per our registry based study in intermediate risk AML results of HSCT from matched sibling donor are superior to those of HAPLO-HSCT, while in high risk-AML relapse is lower in the HAPLO transplants and NRM, LFS and OS is similar

S494

INDIVIDUAL OUTCOME PREDICTION FOR MDS AND SECONDARY AML AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION BASED ON GENETIC, PATIENT- AND TRANSPLANTATION-ASSOCIATED RISK FACTORS

M. Heuser[1,*], R. Gabdoulline[1], P. Loeffeld[1], V. Dobbernack[1], H. Kreimeyer[1], M. Pankratz[1], M. Flintrop[1], V. Panagiota[1], M. Stadler[1], M. Wichmann[1], R. Shaswar[1], U. Platzbecker[2], C. Thiede[2], T. Schroeder[3], G. Kobbe[3], R. Geffers[4], B. Schlegelberger[1], G. Göhring[1], H.-H. Kreipe[1], U. Germing[3], A. Ganser[1], N. Kroeger[5], C. Koenecke[1], F. Thol[1]
[1]Hannover Medical School, Hannover, [2]Universtitätsklinikum Carl Gustav Carus, Dresden, [3]Heinrich Heine University, Duesseldorf, [4]Helmholtz Centre for Infection Research, Braunschweig, [5]University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Prediction of individual outcomes after allogeneic hematopoietic cell transplantation (alloHCT) is difficult, as it is influenced by a multitude of risk factors.
Aims: To develop a tool that predicts individual outcomes of patients with myelodysplastic syndrome (MDS) or secondary acute myeloid leukemia from MDS (sAML) after alloHCT.
Methods: We integrated molecular data with available prognostic factors in patients undergoing alloHCT for MDS and sAML to evaluate their impact on prognosis. 304 patients with MDS or sAML who underwent alloHCT were sequenced for mutations in 54 genes. We used a Cox multivariate model and competing risk analysis with internal and cross validation to identify factors prognostic of overall survival (OS), cumulative incidence of relapse (CIR) and non-relapse mortality (NRM).

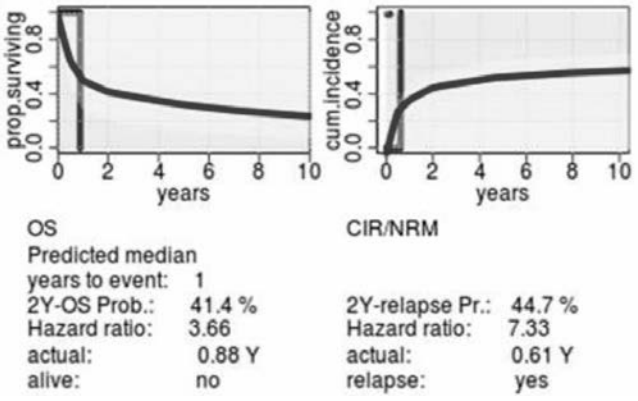

Figure 1.

Results: In multivariate analysis, mutated *NRAS, U2AF1, IDH2, TP53* and/or a complex karyotype were significant prognostic markers for OS besides age above 60 years, remission status treated but not in CR, IPSS-R cytogenetic risk, HCT-CI >2 and female donor sex. Mutated *NRAS, IDH1, EZH2* and *TP53* and/or a complex karyotype were genetic aberrations with prognostic impact on CIR. No molecular markers were associated with the risk of NRM. The addition of molecular information significantly improved the risk prediction for OS and CIR as assessed by the Akaike information criterion. Internal and cross validation confirmed the robustness of our comprehensive risk model. We developed an interactive risk prediction tool to provide personalized predictions for OS, CIR and NRM outcome after alloHCT. An individualized prediction for a 53-year-old male with sAML with trisomy 11, mutated *NRAS, IDH2* and *DNMT3A* and complete remission after double induction is shown in Figure 1. The probability of CIR at 2 years was 45% and the patient relapsed after 0.61 years. The probability of OS at 2 years was 41% and the patient died after 0.88 years.

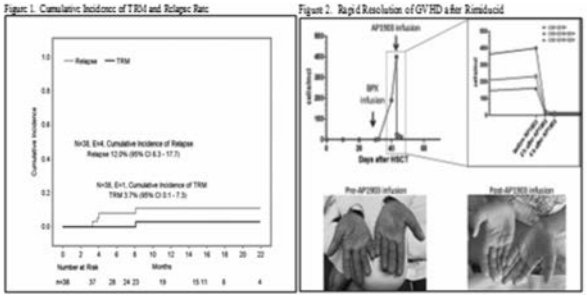
Summary/Conclusions: We combine molecular, cytogenetic, patient- and transplantation associated risk factors into a comprehensive risk score to provide personalized predictions for outcome after alloHCT. Upon validation in larger patient cohorts, this will improve patient information before alloHCT and provide a platform to improve treatment strategies for patients with high risk of CIR or NRM.

S495

IMPACT OF POST-TRANSPLANT INFUSION OF DONOR T CELLS GENETICALLY MODIFIED WITH INDUCIBLE CASPASE 9 SUICIDE GENE (BPX-501 CELLS) ON CHILDREN WITH LEUKEMIA GIVEN ALPHA-BETA T-CELL DEPLETED HAPLO-HSCT

P. Merli[1,*], A. Bertaina[1], F. Galaverna[1], M. Algeri[1], D. Pagliara[1], G. Li Pira[1], J. Weinberg[2], A. Moseley[2], F. Locatelli[1]
[1]Ospedale Pediatrico Bambino Gesu, Rome, Italy, [2]Bellicum Pharmaceuticals Inc., Houston, United States

Background: HLA-haploidentical allogeneic hematopoietic stem cell transplant (haplo-HSCT) offers an option for children with acute leukemia in need of a transplant and lacking an available HLA-identical donor. However, performing haploidentical-HSCT without any graft manipulation has historically been associated with a high risk of acute and chronic graft-versus-host disease (GVHD). T cell depletion reduces the risk of GVHD, but leads to delayed immune reconstitution, predisposing to serious infection and leukemia relapse due to the lack of a T-cell mediated graft-versus-leukemia (GvL). To address these challenges, we have infused mature BPX-501 T cells (donor peripheral lymphocytes which have been modified with the iCasp9 suicide gene) after αβ T-cell depleted haplo HSCT to facilitate immune reconstitution and GvL effect. BPX-501 T-cells are genetically modified with the iCasp9 suicide safety switch and a truncated CD19 marker. In the event of GvHD, the switch is activated by an infusion of the drug rimiducid (AP1903) resulting in rapid T cell apoptosis and GvHD reversal. CD3+/CD19+ T-cells can be tracked by flow cytometry.
Aims: This study was performed to evaluate both safety and efficacy of BPX-501 T cell infusion post αβ T-cell depleted haplo HSCT in pediatric patients with high risk ALL and AML in CR1 and CR2.
Methods: : A prospective Phase I-II study enrolling children with hematopoietic disorder who lack a matched donor. 38 patients have been enrolled and treated with αβ TCR depleted haplo HSCT after a myeloablative preparative regimen followed by BPX-T cell infusion to date; of them, 24 had ALL and 14 AML (21% CR1, 79% CR2). Median follow-up is 11 months (range 3-24).
Results: All patients engrafted and no secondary graft failure was recorded. Median time to neutrophil and platelet recovery was 16 days (range 8-33) and 11 days (range 7-19), respectively. With a median follow-up of 11 months (range 3-24 months), the cumulative incidence of NRM and relapse was 3.7% and 12.0%, respectively, while the disease-free survival probability was 84.2% (Fig 1). All aGVHD resolved (5 Grade I skin, 5 Grade II skin, 2 Grade III GI). One child received rimiducid to treat steroid-resistant grade II skin with complete resolution in 24 hours (Fig 2). There were 3 cases of chronic GvHD, 2 were mild; 1 severe and fatal in a patient whose donor had VZV reactivation during mobilization. CD3+ T cells reached 500 cells/μl by day 90, with normalized CD4/CD8 T cell ratio by day 180.



Figures.

Summary/Conclusions: Engraftment was brisk and T cell recovery normalized by 6 months. Overall incidence of severe aGVHD was low and the safety switch was successfully activated with rimiducid infusion. Cumulative incidence of NRM compares favorably to historic controls at the lead center, where a value of of 2.4% for matched related donors (MR), 11.8% for matched unrelated donors (MUD) and 5% for αβ T cell depletion haplo HSCT (Haplo αβ) without BPX-501 infusion was recorded (Bertaina, 2015 ASH). The cumulative incidence of relapse was 12.0% for BPX-501, 32.3% for MR, 22.2% for MUDs and 21.9% Haplo-αβ. Disease-free survival in the BPX-501 treated patients was 84.2% compared to 65.4% for MR, 66.1% for MUDs and 73.1% for Haplo-αβ. However, length of follow-up on the control cohorts differed from that of BPX-501 treated patients. These data suggest that BPX-501 T cells modified with the iCasp9 safety switch, infused after selective αβ T-cell depletion, are safe and result in a rapid immune reconstitution and a potentially stronger GvL effect in children with high-risk leukemia who lack a matched donor.

Bone marrow failure and PNH

HEREDITARY HEMATOLOGIC MALIGNANCIES: GENETIC COUNSELING IMPLEMENTATION IN A LARGE LEUKEMIA CENTER

C. Dinardo[1,*], S. Bannon[2], K. Takahashi[1], C. Benton[1], M. Routbort[3], N. Pemmaraju[1], N. Daver[1], T. Kadia[1], G. Garcia-Manero[1], K. Patel[3], H. Kantarjian[1], A. Futreal[4]
[1]Leukemia, [2]Clinical Cancer Genetics, [3]Hematopathology, [4]Genomic Medicine, The University of Texas MD Andesron Cancer Center, Houston, United States

Background: Hematologic malignancies have rarely been targets for genetic evaluation, even in familial cases. Over the past decade, more than 12 genes have been identified to cause inherited predispositions to hematologic malignancies. Genetic counseling, testing, and surveillance protocols for these families are not well-established. Additionally, many families with high incidence of blood cancers do not have described syndromes suggesting additional genes remain to be identified.
Aims: To identify individuals with inherited susceptibilities to hematologic malignancies, the Hereditary Hematologic Malignancy Clinic (HHMC) was established in April 2014 at The University of Texas M. D. Anderson Cancer Center. The clinic provides genetic counseling, clinical and research testing for patients with hematologic malignancies suspected to have inherited predisposition syndromes.
Methods: Individuals were referred to the HHMC for several indications: (1) bone marrow failure/aplastic anemia/hypocellular MDS, (2) personal history of hematologic malignancy with ≥1 first-degree relative or ≥2 second-degree relatives with hematologic malignancy, (3) personal history of multiple primary cancers, (4) germline evaluation of presumed somatic mutations identified on next-generation leukemia prognostication panels, (5) management and/or surveillance of a previously-identified genetic syndrome, or (6) solid tumor hereditary syndrome evaluation in patients with active hematologic malignancy. Over the past 3 years, 152 probands were evaluated (n=152). Skin biopsies were performed to obtain germline DNA, and next-generation sequencing approaches on both a clinical and research basis were utilized.
Results: Clinical genetic testing was performed in 97/152 individuals (64%). Research testing was performed in 46/152 (30%), particularly in patients negative for known susceptibility genes or without features suggestive of a clinical syndrome. Nine (6%) individuals did not undergo genetic testing. Clinical testing identified 23/97 (24%) individuals with a germline susceptibility to hematologic malignancy. Seven probands (7%) were identified to have *RUNX1* mutations associated with familial platelet disorder with myeloid malignancy (FPD-AML). Six (6%) were identified to have the telomere disorder dyskeratosis congenita; only one of them met clinical diagnostic criteria with the "classic triad" of symptoms. Three (3%) patients were identified to have Li-Fraumeni syndrome due to constitutional *TP53* mutations. Two adults (2%) were diagnosed with Diamond-Blackfan anemia; both of these individuals developed adult-onset myelodysplastic syndrome after a long latency period and prior spontaneous remission of their childhood anemia. Two young adults (2%) with Fanconi anemia were diagnosed, and one patient each with *DDX41* mutation and *CBL* (Noonan-like syndrome with JMML) were identified. Counseling, testing, and surveillance of identified mutation carriers in many affected families is ongoing.
Summary/Conclusions: Individuals with hereditary susceptibilities to hematologic malignancies are not as rare as previously thought. Clinical evaluation of these patients through genetic counseling and testing is high yield for identified at-risk families. Research-based sequencing for novel mutations is indicated and ongoing.

S497

SECONDARY LEUKEMIAS IN GENETIC SUBTYPES OF CONGENITAL NEUTROPENIA (ELANE, HAX1, WASP, G6PC3, ETC.): A LONG-TERM ANALYSIS OF THE SCNIR EUROPE

C. Zeidler[1,*], M. Klimiankou[2], A. Nickel[1], S. Mellor-Heineke[1], J. Skokowa[2], K. Welte[3]
[1]SCNIR, Medical School Hannover, Hannover, [2]Department of Hematology, Oncology, Clinical Immunology, [3]Department of General Pediatrics and Pediatric Hematology and Oncology, University of Tuebingen, Tuebingen, Germany

Background: Leukemia predisposition is well known in congenital neutropenia (CN) subtypes. By taking all patients with known and unclassified CN together the incidence of secondary leukemia accounts for more than 10 percent. Advanced molecular diagnostics and the identification of inherited and acquired gene mutations have improved our understanding of leukemic transformation in CN patients.
Aims: In the European SCNIR 449 patients with congenital neutropenia and 91 patients with cyclic neutropenia (CyN) have been enrolled since 1994. These 449 patients can be differentiated by causative gene mutation in more than 10 genetic subtypes: *ELANE, HAX1, G6PT, G6PC3, WAS, SBDS, TAZ1* and *p14* or no identified mutation, respectively. Our aim is to assess the risk of leukemic transformation within these genetic subgroups.
Methods: Here we report the leukemia incidence of genetic subtypes analyzing all available long-term data from the European Branch of the Severe Chronic Neutropenia Registry (SCNIR). In addition, we analyzed 91 patients with CyN with or without *ELANE* mutations.
Results: Results from genetic testing were available for 314 of 449 CN patients, of whom 118 patients revealed *ELANE*, 48 *HAX1*, 71 *SBDS*, 28 *G6PT*, 9 *G6PC3*, 7 *WAS*, 5 *TAZ1* mutations and 27 other rare gene mutations (*e.g.* p14, CXCR4). 135 patients remain unclassified. In addition, 48 of 91 patients with CyN revealed *ELANE* mutations. Secondary myelodysplastic syndrome (MDS) or leukemia occurred in 49 of the 449 CN patients and in 1 of the 48 ELANE-CyN patients. Acquired *CSF3R* nonsense truncating mutations have been detected in the bone marrow cells of about 80% of CN patients who progress to MDS or acute myeloid leukemia (AML) and around 30-35% of non-leukemic CN patients, supporting the association between the acquisition of *CSF3R* mutations and leukemic transformation. These mutations have been shown to be acquired in hematopoietic cells only and therefore are not the primary cause of CN. The time between first detection of *CSF3R* mutations and signs of malignant transformation is highly variable. Some patients progressed to MDS/AML within a few months. In others, *CSF3R* mutant clones persisted for many years without progression to leukemia. The distribution by genetic subtypes and the frequency of CSF3R mutations is shown in the table below:

Table 1.

Gene Mutation	Patients N	MDS/Leukemia n/ (%)
Total CN	**445**	**49 (11,0)**
ELANE	118	17 (14,4)
HAX1	48	6 (12,5)
SBDS	71	6 (8,5)
SLC37A4	28	1 (3,6)
WAS	7	2
JAGN1	2	1
gene mutations without leukemia*	36	0
unclassified	135	16 (11,8)
Total CyN	**91**	**1 (0.2)**
ELANE CyN	48	1 (0,2)
CyN unclassified	43	**1 (2,3)**

**Gene mutations without leukemia :(G6PC3 n=9, TAZ1 n=5, p14 n=4, digenic mutations n=4, COH1 n=4, CXCR4 n=3, germline extracellular CSF3R n=2, C16ORF57 n=2, Pearson syndrome n=2, LYST n=1)*

All subgroups benefit from G-CSF treatment. However, patients requiring maintenance doses of G-CSF above 8µg/kg/day are at greater risk of leukemic transformation.
Summary/Conclusions: Conclusion: The incidence of secondary AML reflects the genetic heterogeneity of CN.

S498

EFFECT OF ECULIZUMAB IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) PATIENTS WITH OR WITHOUT HIGH DISEASE ACTIVITY: RESULTS FROM THE INTERNATIONAL PNH REGISTRY

B. Höchsmann[1,*], F. Sicre de Fontbrune[2], J.W. Lee[3], A. Kulagin[4], P. Hillmen[5], A. Wilson[6], J. Marantz[6], H. Schrezenmeier[1]
[1]Institute for Clinical Transfusion Medicine and Immunogenetics, University Hospital Ulm, Ulm, Germany, [2]Hôpital Saint Louis, Paris, France, [3]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of, [4]Pavlov First Saint Petersburg State Medical University, St. Petersburg, Russian Federation, [5]St. James's University Hospital, Leeds, United Kingdom, [6]Alexion Pharmaceuticals, Inc., Lexington, MA, United States

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, progressive, life-threatening disease caused by somatic phosphatidylinositol glycan class A (*PIGA)* gene mutation in bone marrow stem cells. The International PNH Registry (NCT01374360) is a prospective, multinational, observational study to record the natural history of PNH and collect data on long-term efficacy and safety of treatment with eculizumab (ecu), a humanized monoclonal antibody approved for treatment of PNH.
Aims: Evaluate the effect of ecu in patients with PNH with or without high disease activity (HDA).
Methods: Patients enrolled in the Registry as of December 5, 2016, were stratified by HDA and ecu treatment status into 4 groups: HDA/ecu-treated; HDA/never ecu-treated; no-HDA/ecu-treated; no-HDA/never ecu-treated. HDA is defined as lactate dehydrogenase (LDH) ratio ≥1.5x upper limit of normal within 6 months of baseline and history of any of the following: fatigue, hemoglobinuria, abdominal pain, dyspnea, anemia (hemoglobin <100 g/L), major adverse vascular event (MAVE; including thromboembolism [TE]), dysphagia, or erectile dysfunction. Patients were assessed at baseline (date of enrollment in never ecu-treated patients; date of initiation of ecu in ecu-treated patients) and at last follow-up. Outcomes include changes from baseline to last follow-up in LDH ratio, GPI-deficient granulocytes, red blood cell transfusions received, MAVE, and Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score in patients with at least 6 months of follow-up.

Results: 4717 patients were enrolled; of these, 2670 had non-missing data on ecu and HDA status, and were included in the current analysis (HDA/ecu-treated, n=785; HDA/never ecu-treated, n=636; no-HDA/ecu-treated, n=111; no-HDA/never ecu-treated, n=1138). Median (min, max) duration of follow-up after baseline was longer for the ecu-treated patients compared with the never ecu-treated patients for both the HDA and no-HDA groups (see Table). Results for changes from baseline to last follow-up in outcomes of interest are summarized in the **Table**. Data show that patients in the ecu-treated cohort had high burden of disease at baseline. Specifically, in the HDA population, a higher proportion of ecu-treated patients had a history of MAVE (33.3%) *vs* never ecu-treated patients (13.7%). A similar disparity at baseline was also observed in the no-HDA population (33.0% *vs* 11.0%, respectively). Following ecu treatment, the divergence in the proportion of patients with MAVE has substantially narrowed for the HDA patients (3.9% for ecu-treated *vs* 3.3% for never ecu-treated) despite longer follow-up for the treated patients. Similar findings were seen in no-HDA patients (5.3% *vs* 2.1% respectively). In patients with HDA status, treatment with ecu was associated with meaningful improvement in mean (standard deviation [SD]) reduction from baseline in LDH ratio (-5.0 [3.7] *vs* -0.4 [2.3]) and proportion of red blood cell transfusion-free patients (37.6% *vs* 15.8%). The FACIT-Fatigue data, while limited, showed the HDA/ecu-treated group experienced greater mean (SD) score improvement than the HDA/never ecu-treated group (4.1 [10.3] *vs* 0.5 [6.8] points).

Table 1.

Outcome Measure*	HDA/Ecu-treated (n=785)	HDA/Never Ecu-treated (n=636)	No-HDA/Ecu-treated (n=111)	No-HDA/Never Ecu-treated (n=1138)
	n=767	n=636	n=108	n=1135
Years from baseline to last follow-up, median (min, max)	3.1 (0.0, 11.0)	1.5 (0.0, 10.0)	2.1 (0.1, 11.0)	1.5 (0.0, 9.5)
	n=583	n=356	n=67	n=582
Change from baseline in LDH ratio, mean (SD)	−5.0 (3.7)	−0.4 (2.3)	−0.4 (2.0)	0.2 (0.9)
	n=210	n=107	n=25	n=248
Change from baseline in % GPI-deficient granulocytes, mean (SD)	3.5 (23.9)	−0.5 (20.2)	6.3 (21.8)	1.3 (17.6)
Change from baseline in number of patients requiring blood transfusions, n (%)	n=599	n=425	n=74	n=747
Yes to no	225 (37.6)	67 (15.8)	21 (28.4)	161 (21.6)
No change	332 (55.4)	317 (74.6)	47 (63.5)	549 (73.5)
No to yes	42 (7.0)	41 (9.6)	6 (8.1)	37 (5.0)
Change from baseline in number of patients with MAVE, n (%)	n=699	n=460	n=94	n=766
Previous history of MAVE and occurrence of MAVE after baseline	17 (2.4)	3 (0.7)	3 (3.2)	4 (0.5)
Previous history of MAVE and no occurrence of MAVE after baseline	216 (30.9)	60 (13.0)	28 (29.8)	80 (10.4)
No previous history of MAVE and occurrence of MAVE after baseline	10 (1.4)	12 (2.6)	2 (2.1)	12 (1.6)
No previous history of MAVE and no occurrence of MAVE after baseline	456 (65.2)	385 (83.7)	61 (64.9)	670 (87.5)
Change from baseline in FACIT-Fatigue score, mean (SD)	4.1 (10.3)	0.5 (6.8)	−3.8 (14.5)	0.3 (7.7)

*All analyses of change from baseline to last follow-up were restricted to patients with at least 6 months of follow-up and who had data at both baseline and last follow-up time points. Abbreviations: Ecu, eculizumab; FACIT, Functional Assessment of Chronic Illness Therapy; GPI, glycosylphosphatidylinositol; HDA, high disease activity; LDH, lactate dehydrogenase; MAVE, major adverse vascular event; SD, standard deviation.

Summary/Conclusions: Our analysis of real-world data from the International PNH Registry has demonstrated that treatment with eculizumab was associated with improved outcomes in patients with HDA. Our findings are consistent with the notion that patients with HDA, including those with a history of MAVE, should be treated with eculizumab.

Background: Thrombopoietin (Tpo) and its receptor, Mpl, are the principal regulators of early/late thrombopoiesis and hematopoietic stem cells maintenance. Mutations in *MPL* can drastically impair its function and be a contributing factor in multiple hematologic malignancies, including congenital amegakaryocytic thrombocytopenia (CAMT). CAMT is a rare inherited syndrome characterized by thrombocytopenia at birth, progressing to bone marrow failure and pancytopenia. The functional impact of CAMT mutations on Mpl is yet to be determined. Here we report unique familial cases of CAMT presenting with a previously unreported *MPL* mutation: T814C (W272R) in the background of the activating *MPL* G117T (K39N or Baltimore) mutation.
Aims: This study focuses on the functional characterization of this novel Mpl mutant and the use of genome editing as a novel therapeutic option for CAMT.
Methods: Human megakaryoblastic UT-7 and murine Ba/F3 cells stably expressing human wild-type (WT) Mpl or mutant Mpl fused to mNeonGreen were used as models. Confocal microscopy, proliferation and surface biotinylation assays, as well as co-immunoprecipitation and western blotting analysis, were used to elucidate the function and trafficking of Mpl mutants. Multiplex, flow-based, CRISPR-Cas9 gene editing was used to repair mutant *MPL* and rescue its function. Cord blood from the younger male sibling was used as a source of primary homozygous Mpl K39N/W272R CD34$^+$ cells. CD34$^+$ cells were edited using ribonucleoproteins electroporation followed by sequencing and functional assays such as flow cytometry and single colony assays.
Results: Consanguineous parents and their eldest daughter, all heterozygous for Mpl K39N/W272R, do not present any signs of disease. Their monozygotic twin daughters presented at birth with severe thrombocytopenia leading to a diagnosis of CAMT type I. Whole blood sequencing revealed the presence of a homozygous double Mpl K39N/W272R mutation, as their younger male sibling. One of the twins died after bone marrow transplant. Confocal microscopy shows that a significant fraction of chimeric WT Mpl protein reaches the cell surface. Significant surface expression is also noted for Mpl K39N. In contrast, the chimeric Mpl protein bearing the W272R mutation, alone or together with the K39N mutation, showed no detectable surface expression of the Tpo receptor while being strongly co-localized with ER marker calreticulin. Both WT and K39N-mutated Mpl were found signaling competent, while single or double mutants bearing W272R were unresponsive to Tpo. Tpo-induced signaling was partially restored via GRASP55 over-expression (forcing ER-trapped Mpl to traffic to the cell surface). Genome editing performed on cells carrying the W272R mutation restored the WT sequence and the response to Tpo, with similar cell proliferation as WT Mpl cells. Finally, when applied to primary Mpl K39N/W272R CD34$^+$ cells, CRISPR-based gene editing rescued surface expression of Mpl and response to Tpo, as assessed by flow cytometry. Furthermore, edited CD34$^+$ cells were able to generate a similar number of megakaryocytic colonies as control CD34$^+$ cells in a single colony assay. Non-edited cells failed to do so.
Summary/Conclusions: We report a new double *in cis* mutation of Mpl (K39N/W272R) in the context of CAMT. Function of the deficient Mpl receptor could be rescued using two separate approaches: GRASP55 over-expression and CRISPR-Cas9 genome engineering. Successful editing of primary hematopoietic stem cells indicates direct therapeutic applications for gene editing in this disease.

DISCOVERY OF ORALLY BIOAVAILABLE SMALL MOLECULES FOR INHIBITION OF COMPLEMENT C5

A. Ricardo[1,*], M.D. Hoarty[1], J.C. Blain[1], S.J. DeMarco[1], V. Galullo[1], M.R. Hale[1], E. de Koning[1], D. LaPlaca[1], K. Seyb[1], J.R. Stringer[1], G.-Q. Tang[1], J. Tikhe[1], D. Vadysirisack[1], R. Vyasamneni[1]
[1]Ra Pharmaceuticals, Inc., CAMBRIDGE, United States

Background: Paroxysmal nocturnal hemoglobinuria (PNH) and atypical hemolytic uremic syndrome (aHUS) are well-characterized diseases of complement dysregulation. The only approved therapeutic for these diseases is Soliris® (Eculizumab, Alexion), a monoclonal antibody that binds and inhibits the cleavage of complement C5. Soliris® requires lifelong intravenous administration by a medical professional every two weeks. An orally bioavailable small molecule inhibitor of complement C5 to treat these and other complement mediated diseases represents a potential paradigm shift in the treatment of diseases of complement dysregulation.
Aims: To demonstrate the utility of an orally available, small molecule Complement C5 inhibitor for the treatment of complement mediated disorders.
Methods: Surface Plasmon Resonance (SPR) and Fluorescent Polarization assays (FP) were used to evaluate the affinity and specificity of the binding interaction between complement C5 and small molecule inhibitors. Determination of binding site, mechanism of action and potency were achieved by X-ray crystallography studies, Wieslab ELISA, and a sheep erythrocyte hemolysis based assay. The ability of the small molecules to prevent the hemolysis of PNH erythrocytes was evaluated using a modified Ham test. Pharmacokinetic studies were performed in rodents.
Results: Here we describe a series of first in class, orally bioavailable small molecules that bind to C5 with high affinity and inhibit its cleavage into C5a and C5b. These molecules demonstrate desirable drug-like properties with molecular weights under 500 amu and tPSA<100 Å2. A high-resolution co-crystal structure with C5 shows a unique binding site on the 188 kDa C5 protein, and specific binding of these molecules to C5 has been demonstrated by surface plasmon resonance (SPR) and fluorescence polarization (FP) assays. The position of the binding site suggests that these molecules will inhibit C5 cleavage in patients with the R885H/C polymorphism, which confers resistance to eculizumab. The molecules inhibit the terminal complement complex activity with single digit nanomolar IC50 as measured by inhibition of hemolysis in a highly sensitive antibody-sensitized sheep erythrocytes assay. In addition, they inhibit MAC deposition on complement-activating surfaces and prevent the cleavage of C5 to C5a and C5b as confirmed by ELISAs that directly detect generation of C5a and MAC. This series of inhibitors prevents the complement-mediated hemolysis of PNH erythrocytes (Type III) in a dose-dependent manner. More broadly, this series of molecules has been profiled by *in vitro* and *in vivo* ADME disposition studies and exhibits oral bioavailability (%F~30-50) in pre-clinical species.
Summary/Conclusions: The results presented here highlight, for the first time, the feasibility of an oral, potent small molecule inhibitor of C5. The development of an orally available complement C5 inhibitor has the potential to provide a new therapeutic modality to treat both rare and common conditions where terminal complement cascade inhibition is desired.

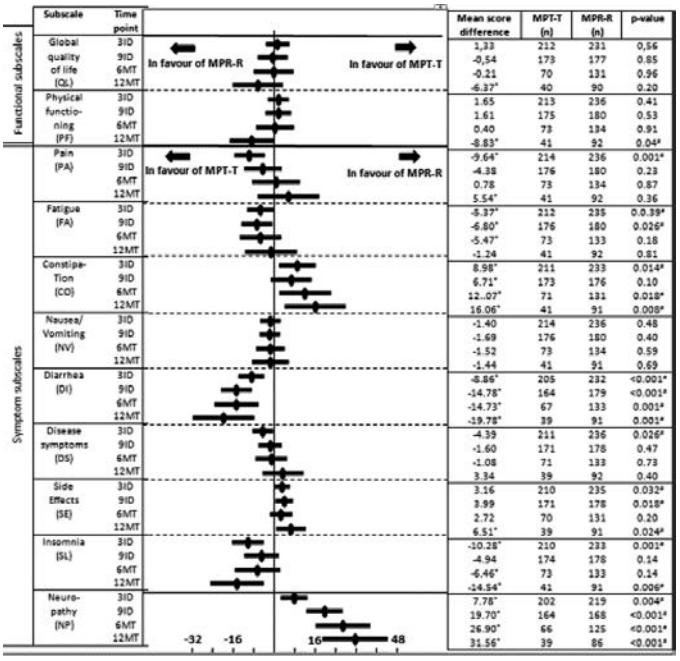
Background: We recently reported the results of the phase III randomized HOVON87/NMSG18 study showing comparable efficacy of treatment with melphalan, prednisolone and thalidomide following by thalidomide maintenance (MPT-T) *versus* melphalan, prednisolone and lenalidomide followed by lenalidomide maintenance (MPR-R) (Zweegman S *et al.* Blood 2016;127(9):1109-1116). As not only efficacy but also potential toxicity affecting quality of life (QoL) guides the choice of treatment, health-related (HR) QoL is important.
Aims: To evaluate the HRQoL results of the HOVON87/NMSG18 study.
Methods: Two validated HRQoL instruments (EORTC QLQ-C30 and MY20) were obtained at baseline, after 3 and 9 induction cycles (3ID and 9ID) and after 6 and 12 months of maintenance therapy (6MT and 12MT). The subscales global QoL, physical functioning, pain, fatigue, constipation, diarrhea, nausea/vomiting, insomnia, disease symptoms, side effects of treatment and neuropathy were analysed. Change in HRQoL score over time between treatment arms was assessed by linear mixed models. Independent sample t-tests were used to determine changes from baseline. Minimal important difference (MID) within arms was defined as a difference in score of ≥1 standard error of measurement (SEM) or, if a subscale consisted of one parameter only, MID-levels described in previous literature were used. To determine clinically relevant superiority of one arm, a difference in score of ≥5 was used and in addition significance level was calculated.
Results: From 553 (90.2%) of the 613 patients who participated in the HRQoL part of the study a baseline questionnaire was available. Forty (15%) of patients randomized to MPT-T *versus* 68 (24%) of patients randomized to MPR-R completed therapy until 12 months of maintenance therapy. *Change in HRQoL between arms over time:* in MPT-T improvement of HRQoL over time as compared to MPR-R was found for the subscales diarrhea and insomnia. In contrast, MPR-R showed improvement over time for the subscales pain, constipation, side effects of treatment and neuropathy, as compared to MPT-T. *Change in HRQoL per arm:* In MPT-T MID was reached for the following subscales; global QoL increased after 9ID until 12MT (MID range 7-13), pain decreased at every time point (MID range -21 to -23), disease symptoms deceased after 9ID (MID -12), fatigue decreased during MT (MID 12) and insomnia decreased at each time point (MID range -11 to -21). In MPR-R the MID was reached for the following subscales; global QoL increased after 9ID until 12MT (MID range 8-14), physical functioning increased at 12MT (MID 13), pain decreased at every time point (MID range -14 to -26) and insomnia decreased at 6MT (MID -10). *Difference between MPT-T and MPR-R:* In the MPT-T arm significantly ($p<0.05$) and/or clinically (mean score difference (MSD) ≥5 points) less pain and disease symptoms at 3ID, less fatigue at 3ID and 9ID, less diarrhea and less insomnia at all time points were observed. In contrast, patients on MPR-R reported better global QoL, better physical functioning and less pain at 12MT, in general less side effects of treatment, and less constipation and neuropathy separately, at all time points than patients treated with MPT-T.

Table 1.



Summary/Conclusions: Both treatment with MPT-T and MPR-R controlled pain and resulted in an improvement in global QoL as compared to baseline after 9ID and during maintenance. Treatment with thalidomide initially resulted in less pain and disease symptoms. At all treatment stages thalidomide caused less diarrhea, fatigue and insomnia as compared to treatment with lenalidomide. In contrast, therapy with lenalidomide resulted in less side effects of treatment, less constipation and less neuropathy as compared to thalidomide at all stages of treatment. In addition, long term maintenance therapy with lenalidomide resulted in better global QoL, better physical functioning and less pain.

Hoffmann-La Roche Ltd, Basel, Switzerland, [17]Ludwig-Maximilians-University Munich, Munich, Germany

Background: Maintenance of pretreatment health-related quality of life (HRQoL) and/or meaningful improvements in HRQoL are important for previously untreated indolent non-Hodgkin lymphoma (iNHL) patients (pts). GALLI-

UM (NCT01332968) is an open-label, randomized Phase III study of obinutuzumab (GA101; G) plus chemotherapy (chemo) followed by G maintenance (G-chemo) compared with rituximab (R) plus chemo followed by R maintenance (R-chemo) in pts with previously untreated iNHL. In GALLIUM, G-chemo produced a clinically meaningful improvement in investigator-assessed progression-free survival (PFS) among follicular lymphoma (FL) pts (34% reduction in risk of a PFS event relative to R-chemo). Grade 3–5 and serious adverse events were more common with G-chemo.
Aims: To compare changes in HRQoL in FL pts receiving G-chemo and R-chemo during GALLIUM.

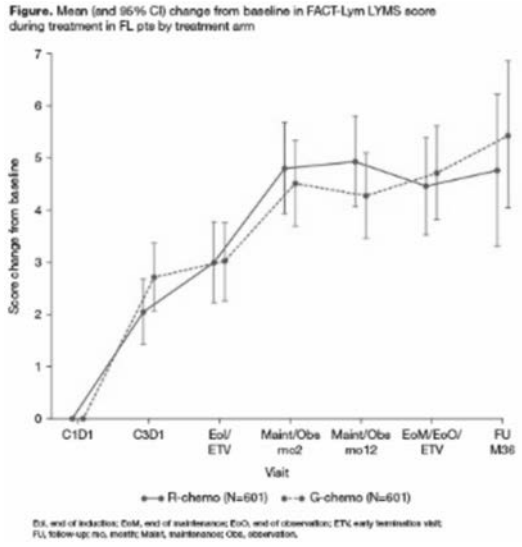

Figure 1.

Methods: Enrolled pts were aged ≥18 years with documented, previously untreated FL (grades 1-3a), advanced disease (stage III/IV or stage II with tumor diameter ≥7cm), ECOG performance status 0-2, and requiring treatment according to GELF criteria. Pts were randomized 1:1 to R 375mg/m^2 on day (D) 1 of each cycle (C) or G 1000mg on D1, 8, and 15 of C1 and D1 of C2-8, for 6 or 8 cycles depending on chemo (CHOP, CVP or bendamustine). Responders continued to receive R or G every 2 months (mo) for 2 years or until progression. The Functional Assessment of Cancer Treatment-Lymphoma (FACT-Lym) questionnaire (Webster *et al.* 2005) was used to assess overall HRQoL, physical and functional well-being, and disease- and treatment-related symptoms. FACT-Lym was administered on D1 of C1 and C3 during induction, at the end of induction, and at mo 2 and 12 during maintenance/follow-up. For each FACT-Lym scale, mean and 95% confidence interval (CI) were derived for recorded scores at each visit and changes from baseline. Minimally important differences (MIDs) were used to calculate the proportion of pts reporting improvement on the FACT-Lym lymphoma subscale (LYMS; ≥3 points), Trial Outcome Index (TOI; ≥6 points), and lymphoma total score (Lym-Total; ≥7 points). All pts gave informed consent.
Results: Of 1202 FL pts randomized (median age, 59 yrs; 53.2% female; median observation time, 34.5 mo [range 0-54.5]), 556/601 (92.5%; G-chemo) and 550/601 (91.5%; R-chemo) completed all FACT-Lym scales at baseline. Baseline demographics and disease characteristics were balanced between arms. At baseline, mean HRQoL scores were similar in the two treatment arms, with all pts having some impairment of physical function, functional wellbeing, emotional and social function. Over the course of treatment, mean HRQoL was similar in the two treatment arms. From end of induction onwards, pts in both arms experienced clinically meaningful improvements from baseline in LYMS scores (Figure), and the summary scales that included this subscale (TOI, Lym-Total). On each summary scale, ~50% of patients in each arm reported clinically meaningful improvements. There were no clear differences between arms in HRQoL scores over the course of therapy.
Summary/Conclusions: In previously untreated FL pts in GALLIUM, G-chemo and R-chemo produced similar improvements in HRQoL. These results suggest that lymphoma-related symptoms were reduced by both treatments and that the resulting improvements in well-being were not abrogated by treatment-related side effects. When viewed in the context of longer PFS, these results further support the relative benefit of G-chemo over R-chemo in GALLIUM.

S503

EFFECTIVE KEY WORKERS REDUCE THE NEED FOR CANCER SUPPORT GROUPS: RESULTS OF A POPULATION BASED SURVEY FROM GREATER MANCHESTER CANCER PATHWAY BOARD (GMCPB)

J. Tomlins[1,*], C. Wardley[2], C. Quillinan[3], J. Golding[4], E. Cowell[4], A.-M. Kelly[1], K. Bolton[5], M. Dennis[1], N. Remmington[6]

[1]The Christie NHS Foundation Trust, [2]Pennine Acute NHS Trust, [3]Central Manchester NHS Foundation Trust, [4]Wrightington, Wigan and Leigh NHS foundation Trust, [5]stockport NHS foundation Trust, [6]Greater Manchester Cancer Pathway Board, Manchester, United Kingdom

Background: Cancer patient support groups appear to provide an important source of support to many patients and carers. In recent years there has been an increasing focus in the UK for services to provide cancer support groups, however it is unclear what proportion of patients believe access to these support groups would improve their experience of living with and beyond cancer.
Aims: A patient experience survey was undertaken by the Haematology-Oncology GMCPB across 10 NHS hospital trusts, where there are a number of cancer support groups.
Methods: The sample for the survey included all adult (aged >16) patients with a confirmed diagnosis of a haematological cancer who attended a haematological oncology outpatient appointment during a 4 month period (June-September 2016). The survey was available for competition on paper or online and was completed anonymously. A translation/interpretation facility was not provided for patients whose first language was not English (due to funding restraints).
Results: 277 responses were returned with 1 response excluded (non-haematological malignancy). Haematological diagnoses included acute leukaemia (n=40), chronic leukaemia (n=35), lymphoma (n=62), myeloma (n=102), MDS (n=15), MPD (n=12), other (n=2) and not specified (n=7). 257 (93.1%) patients had received anticancer therapy, 218 (79%) were receiving treatment at the time of survey and 54% had ongoing symptoms related to their treatment or cancer. 197 (71.4%) patients did not want access to a support group, 23 (19%) wanted access, 51 (8.3%) were not aware of the possibility and 6 (1.8%) did not respond. 51.8% of patients were aware of the existing support groups, 38.8% were not sure, 2.9% were not aware and 1.8% did not respond. The cohort of patients who did or did not want access to a support group was analysed further. 88% of patients had been given a key worker (eg clinical nurse specialist, research nurse, advanced nurse practitioner or nurse clinician); of the those 88% were satisfied and 1% were partly satisfied with the support they had received with 11% not responding. 93% (n=231) of patients were satisfied with the information they had received at diagnosis and 90% (n=224) felt their diagnosis had been given sensitively. Only 20% of patients currently on treatment wanted access to a support group and 24% not on treatment wanted access to a support group. Date of diagnosis was divided into three groups. Grp A: before 2005 (n=15), Grp B: after 2006 (n=229) and not stated (n=14). There was no difference in the three groups when asked if they wanted access to support group (13%, 22%, 7% respectively; p=0.3) or awareness that support group was available (40%, 57%, 50% respectively; p=0.6). There were additional comments from patients that support from family and online forums in addition to key workers was extremely valuable to them. On univariate analysis patients who were satisfied with their key worker support did not want access to a support group (p=0.04). There was no effect on wanting access to a support group and diagnosis (p=0.67), treating hospital (p=0.5), information given (p=0.6), need for in-patient treatment (p=0.3), quality of care (p=0.8) or satisfaction with overall care (p=0.8).
Summary/Conclusions: Our results suggest that a large majority of patients with a haematological malignancy do not want access to a cancer support group but providing satisfactory support through key workers and other health care professionals is likely to achieve better patient experiences.
Acknowledgements: We would like to acknowledge the members of the GMCPB and patients for their contribution to the survey.

S504

FRONT-LINE VASCULAR ACCESS DEVICES IN ACUTE LEUKEMIAS-PERIPHERALLY INSERTED CENTRAL CATHETER (PICC) VERSUS TRADITIONAL CENTRAL VENOUS CATHETER (CVC): A PHASE IV RANDOMIZED TRIAL (NCT02405728)

C. Cerchione[1,*], M. Di Perna[1], R. Della Pepa[1], N. Pugliese[1], F. Pane[1], M. Picardi[1]
[1]Hematology, Ematologia e trapianto/au federico ii, Napoli, Italy

Background: The use of PICC as an alternative to other CVC devices, particularly for prolonged infusions of cytotoxic agents, blood products and/or other supportive therapy, is becoming very frequent in cancer patients. PICCs are easier to insert, and associated to a lower rate of severe complications than traditional CVCs. However, there is limited information on the feasibility and safety of PICC as primary vascular access device in the setting of high-risk hematological patients.
Aims: Our Hematology Department is conducting a Phase IV randomized trial on this topic. We compare PICCs *versus* traditional CVCs as front-line venous access device in patients with acute leukemias undergoing intensive chemotherapy for remission induction (NCT02405728; ongoing). Primary endpoint is the occurrence of catheter-related bloodstream infections and/or thrombosis. Secondary endpoints are the occurrence of other complications, such as pneumothorax or catheter occlusion, and patients'quality of life. Questionnaire covering functional status, sleep and hygiene disturbance had been given to assess patients' quality of life.

Methods: From April 2015 to February 2017, 152 consecutive patients with acute leukemia planned for remission induction chemotherapy were randomly assigned (1:1) to PICC (Arm A) or traditional CVC (Arm B) (Table 1). Inclusion criteria were age >18 years, expected survival >4 weeks, and need of central venous access (long-term >4 weeks). Exclusion criteria were ongoing uncontrolled systemic infection, presence of significant thrombosis/stenosis in arm or central veins, and inability to communicate and/or to sign informed consent. All insertions were followed by ultrasonography assessments and chest X-ray.
Results: 152 patients (130 AML and 22 ALL) with a median age of 47 years (range, 13-82), were randomized in the two arms. In the Arm A, 76 PICCs (power injectable PICCs, in new generation polyurethane, open-ended) were inserted in 76 patients. Double lumen PICCs (5 Fr) were inserted in 70 patients, single lumen PICCs (4 Fr) were inserted in 5 patients, and triple lumen PICC (6 Fr) was inserted in 1 patient. 68 PICCs were inserted in the right basilica vein, 5 PICCs were inserted in the left basilica vein and 3 PICCs were inserted in the left brachial vein. In Arm B, 76 traditional CVCs (untunneled heparin-coated Vialon CVC, Becton-Dickinson) were inserted by the Seldinger technique in other 76 patients. 45 CVCs were inserted in subclavian vein and 31 CVCs were inserted in internal jugular vein. Overall, the median duration of *in situ* catheter placement was 5 months: 6 months (range, 3-12) in the arm A *vs.* 3 months (range, 1-10) in the arm B. In the arm A, catheter-related thrombosis occurred in 8 patients (6 basilica veins, 2 brachial veins) and catheter-related bloodstream infections in 4 patients (4 coagulase-negative *staphylococci*; of them, 2 meticillin-resistants). In the arm B, 20 cases of catheter-related thrombosis (7 subclavian veins, 13 internal jugular veins) and 15 cases of catheter-related bloodstream infections (10 *enterobacteriaceae;* 5 coagulase-negative *staphylococci,* and, of them, 3 meticillin-resistants) were observed. Thus, PICCs were significantly associated with fewer major complications than traditional CVCs (catheter-related thrombosis: 10.5% in the arm A *vs.* 26% in the arm B, p=0.01 by $\chi 2$ test; catheter-related bloodstream infections: 5% in the arm A *vs.* 19% in the arm B, p= 0.007 by $\chi 2$ test) (Figure 1). Questionnaire covering activities of daily living confirmed improvement of quality of life.

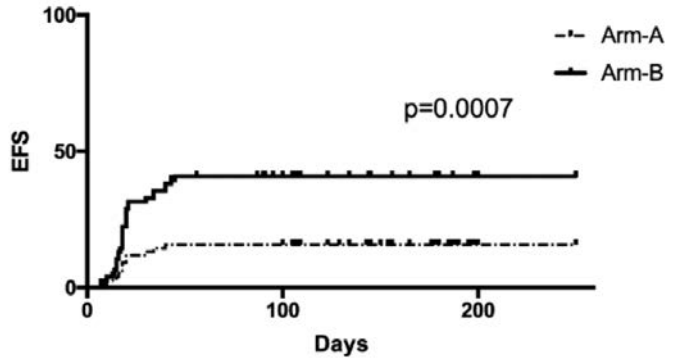

Figure 1.

Summary/Conclusions: The preliminary observations of this ongoing Phase IV randomized study, focusing on front-line use of central venous access device in a high risk hematological population, suggest that the use of PICC represents an advance in terms of decrease of complication rate and improvement of quality of life for patients with acute leukemia.

S505

THE SIMM STUDY: SURVEY OF INTEGRATIVE MEDICINE IN MYELOPROLIFERATIVE NEOPLASMS

K. Gowin[1,*], D. Millstine[2], H. Kosiorek[3], B. Langlais[3], J. Huberty[4], R. Eckert[4], R. Mesa[5]
[1]Hematology and Medical Oncology, [2]Integrative Medicine Program, Department of Medicine, [3]Department of Biostatistics, Mayo Clinic Arizona, [4]School of Nutrition and Health Promotion, Arizona State University, [5]Hematology, Mayo Clinic Arizona, Phoenix, United States

Background: Pharmacologic therapy stabilizes hematologic counts and splenomegaly in myeloproliferative neoplasms (MPN), however only partial symptom improvement typically occurs. Evidenced-based integrative care may address this need, however data is limited in patients with MPNs.
Aims: To investigate integrative therapy utilization association with symptom burden, quality of life, depression, and fatigue in MPN patients.
Methods: Patients were recruited via social media. Informed consent and online self-report surveys (Qualtrics) were completed capturing patient demographics, disease specific data, supportive care utilization, MPN symptom burden via MPN-SAF TSS, depression via Patient Health Questionnaire (PHQ)-9, fatigue via Brief Fatigue Inventory (BFI) Usual, and an overall quality of life (QOL) single question assessment. ANOVA, chi square tests, and Wilcoxon rank sum tests methods were applied.

Results: *Patients*: A total of 1087 patient surveys were consented. Of these, 858 had 10 or more responses. There were 338 essential thrombocytosis (ET), 188 myelofibrosis (MF), 315 polycythemia vera (PV), and 17 other. In MF: DIPSS risk categories included low (8%), Int-1 (19%), Int-2 (29%), high (12%), and unknown (32%). *Symptom association:* Overall, patients had lower MPN related symptoms when participating in aerobic activity (p<0.001), massage (p=<0.001), yoga (p=0.02), strength training (p<0.001), breathing exercises (p=<0.001), and support groups (0.001). Overall quality of life was higher with aerobic activity (p=<0.001), massage (p=0.02), yoga (p=0.02), strength training (p=<0.001), breathing exercises (p=0.01), and support groups (p=0.001). Depression (PHQ-9 total >3 category) was lower in aerobic activity group (p=0.001), yoga (p=0.001), strength training (p=0.001), and meditation (p=0.2). Fatigue was lower in aerobic activity (p=<0.001), massage (p=0.04), strength training (p=<0.001), breathing exercises (p=<0.001), and support groups (p=0.001). In subgroup analysis, ET and PV patients had lower symptom burden (MPN-SAF TSS) with aerobic activity (p=<0.001, <0.001), massage (p= 0.01, 0.02), and strength training (p=0.03,0.02). Support groups were found to be associated with lower symptoms in ET patients (p=0.03). In MF, breathing exercises (p=<0.001) and support groups (p=0.03) were associated with lower symptom burden. See Table #1.

Table 1.

	Overall N = 858				ET N=338	PV N=315	MF N=188
	MPN-SAF TSS	QOL	PHQ-2	BFI-USUAL	MPN-SAF TSS	MPN-SAF TSS	MPN-SAF TSS

Summary/Conclusions: Integrative therapies are associated with improved symptom burden, quality of life, depression, and fatigue in MPN patients. Interestingly, unique patterns were associated within MPN subtypes. Further studies are needed to understand the benefits of integrative therapies in MPN patients.

POSTER SESSIONS II

Acute lymphoblastic leukemia - Biology 2

P506

T CELL EXHAUSTION CHARACTERIZED BY COMPROMISED MHC CLASS I AND II RESTRICTED CYTOTOXIC ACTIVITY ASSOCIATES WITH ACUTE B LYMPHOBLASTIC LEUKEMIA RELAPSE AFTER ALLO-HSCT

L. Liu[1,*], Y. Chang[1], L. Xu[1], X. Zhang[1], Y. Wang[1], K. Liu[1], X. Huang[1]
[1]Peking University People's Hospital & Peking University Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: B cell acute lymphoblastic leukemia (B-ALL) relapse contributes to the predominant mortality after allogeneic hematopoietic stem cell transplantation (allo-HSCT). However, the mechanism of B-ALL relapse after allo-HSCT remains unknown. Eradication of leukemia in allo-HSCT settings largely relies on graft-versus-leukemia (GVL) effects mediated by donor T cells. T cell exhaustion characterized by increased expression of inhibitory receptors including PD-1 and Tim-3 and impaired function may blunt the GVL effects and was reported in acute myeloid leukemia relapse after allo-HSCT. whether T cell exhaustion is involved in B-ALL relapse after allo-HSCT remains unknown.
Aims: To evaluate whether T cell exhaustion is involved in B-ALL relapse after allo-HSCT,and investigate the correlation of inhibitory ligands on leukemic cells, leukemic load and T cell exhaustion, as well as the impact of treatment outcome on T cell exhaustion.
Methods: Our study enrolled 18 B-ALL patients who underwent first hematological relapse after allo-HSCT and18 matched B-ALL patients in remission (without minimal residual disease MRD) and 14 healthy donors from April 2016 to November 2016 at the Peking University People's Hospital, Institute of Hematology. Transplant protocol and post-transplant time were matched in relapsed and non-relapsed patients. Post-transplant time were matched as follows: ±14days within 12 months ±1months from 12 to18months, ±3months from 18 to 36 months, ±12months over 3 years. Extra-medullary relapse were excluded in our study. All patients had achieved full donor chimerism before relapse or bone marrow collection. Peripheral blood (PB) were collected at the same day of bone marrow collection in relapsed patients. For patients who received re-induction therapy, we prospectively collected BM at least once after therapy. Sample collection was performed after patients was informed consent and approval by the institutional Human Ethics Review Committee of Peking University People's Hospital in accordance with the Declaration of Helsinki.phenotypic and functional studies of T cells in those patients were performed using multi-color flow cytometry.
Results: In the current study, we observed that increased co-expression of PD-1 and Tim-3 was observed in both $CD4^+$ and $CD8^+$ T cells in relapse settings. Moreover, both CD4+ and CD8+ T cells exhibited compromised proliferative capacity, cytokine production and cytotoxic potentials such as degranuation and granzyme B production (preferentially on $CD4^+$T cells) in relapsed patients. In addition, T cells at the tumor site are more easily exhausted than those in peripheral blood. Reversal of T cell exhaustion was associated with effective anti-leukemic response in relapsed patients who underwent re-induction therapy.
Summary/Conclusions: In conclusion,our study suggested that T cells experienced exhaustion with comprehensively functional impairments in B-ALL relapse setttings after allo-HSCT and reversal of T cell exhaustion was associated with effective anti-leukemic responses. These results also provide a foundation for the development of novel effective leukemia therapeutics, such as anti-PD-1 or PD-L1 therapy, by targeting T cell exhaustion

P507

RUXOLITINIB/NILOTINIB COTREATMENT BETTER INHIBITS LEUKEMIA-PROPAGATING CELLS IN PHILADELPHIA CHROMOSOME-POSITIVE ALL

Y. Kong[1,*], Y.-L. Wu[12], Y. Song[12], M.-M. Shi[12], X.-N. Cao[1], H.-Y. Zhao[1], Y.-Z. Qin[1], Y.-Y. Lai[1], H. Jiang[1], Q. Jiang[1], X.-J. Huang[1]
[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Relapse remains the major cause of treatment failure in patients with Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph^+ALL), even in the modern era of tyrosine kinase inhibitors (TKIs). Relapse of Ph^+ALL may result from the persistence of leukemia-propagating cells (LPCs), which are defined by their ability to initiate human leukemia and self-renew in immunocompromised mice. Using an anti-CD122-conditioned NOD/SCID xenograft mouse assay, LPCs were reported to be enriched in the $CD34^+CD38^-CD58^-$ fraction in human Ph^+ALL (**YK,…,XJH*. *Leukemia*. 2014**). Furthermore, a cohort study demonstrated that Ph^+ALL patients with LPCs phenotype at diagnosis exhibited a significantly higher cumulative incidence of relapse than did the group with other phenotypes, even when receiving uniform front-line imatinib-based therapy pre- and post-allotransplant (**YK,…,XJH*. *BMT*. 2015**). Therefore, it is imperative to identify novel therapeutic strategies based on LPCs to improve the prognosis of Ph^+ALL patients.
Aims: To identify the potential molecular basis of LPC-mediated relapse, RNA sequencing(RNA-seq) and real-time reverse transcription-PCR (qRT-PCR) were performed to analyze the gene expression profiles of sorted LPCs and cells of other phenotypes from Ph^+ALL patients. To investigate whether selective BCR-ABL/JAK2 dual inhibition therapy could more effectively eliminate LPCs *in vitro* and in humanized Ph^+ALL mice.
Methods: RNA-seq and qRT-PCR were performed to analyze the gene expression profiles of sorted LPCs and cells of other phenotypes from patients with *de novo* Ph^+ALL. In order to assess the effects of the selective BCR-ABL and/or JAK2 inhibition therapy by the treatment with single agents or a combination of ruxolitinib and imatinib or nilotinib on Ph^+ALL LPCs, drug-induced apoptosis of LPCs was investigated in vitro, as well as *in vivo* using sublethally irradiated and anti-CD122-conditioned NOD/SCID xenograft mouse assay. Moreover, western blot analyses were performed on the BM cells harvested from the different groups of recipient mice.
Results: Using RNA-seq and qRT-PCR, we found that JAK2 was more highly expressed in the sorted LPCs than in the cells of other phenotypes in patients with *de novo* Ph^+ALL. *in vitro* study, cotreatment with nilotinib and ruxolitinib induced significantly higher levels of apoptosis in LPCs. In humanized Ph^+ALL mice model, treatment with the nilotinib and ruxolitinib combination, compared with either ruxolitinib or TKIs alone, led to the most significant reduction in human Ph^+ALL engraftment in the recipients. Further evidence that the most effective anti-LPCs effect occurred with the combination treatment was derived by the engraftment analysis of *BCR/ABL* expressing cells using a qRT-PCR assay and HE and IHC with anti-hCD19 staining. Moreover, the combination of nilotinib and ruxolitinib more effectively reduced the LPCs capacity through a deeper suppression of phospho-CrKL, JAK2 and STAT5 activities at the molecular level.
Summary/Conclusions: JAK2 was more highly expressed in the sorted LPCs than in other cell phenotypes in patients with *de novo* Ph^+ALL. Furthermore, selective BCR-ABL/JAK2 dual inhibition with nilotinib/ruxolitinib more effectively eliminated LPCs than either ruxolitinib or TKIs alone. Therefore, this pre-clinical study appears to provide scientific rationale for simultaneously targeting BCR-ABL and JAK2 activities, which represents a promising anti-LPCs therapeutic approach for patients with *de novo* Ph^+ALL.

P508

PREDICTING ANTI-LEUKEMIA ACTIVITY OF THE BCL-2-SELECTIVE INHIBITOR ABT-199 IN BCP-ALL BY FUNCTIONAL ASSESSMENT OF APOPTOSIS SIGNALING

F. Seyfried[1,*], S. Demir[1], R. Hörl[1], J. Ryan[2], A. Scheffold[3], M. Villalobos-Ortiz[2], S. Köhrer[1], J. Zinngrebe[1], S. Stilgenbauer[3], A. Letai[2], K.-M. Debatin[1], L. H. Meyer[1]
[1]Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, Ulm, Germany, [2]Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States, [3]Department of Internal Medicine III, Ulm University Medical Center, Ulm, Germany

Background: Although survival rates of pediatric BCP-ALL patients have continuously improved during the past decades, therapy-related toxicity and relapse occurring in 10-20 % of patients are associated with poor outcome, clearly emphasizing the need of novel, targeted treatment strategies. Deregulated survival pathways and cell death resistance contribute to treatment failure and reoccurrence of the disease. ABT-199 (venetoclax) is a small molecule inhibitor of BCL-2 demonstrating anti-cancer activity among different malignancies. However, predictive biomarkers are required for up-front identification of patients who would benefit from BCL-2 directed therapies.
Aims: The aims of this study were to assess the efficacy of ABT-199 in BCP-ALL, to functionally evaluate factors mediating ABT-199 susceptibility or resistance and to identify markers indicative of successful anti-leukemia activity.
Methods: The activity of ABT-199 was assessed by cell viability assays in BCP-ALL cell lines (N=6) and patient-derived xenograft (pdx) samples (N=27), analyzing half maximal effective concentrations (EC50). Expression of apoptosis regulators was detected by western blot analysis. MCL-1 deficient cell lines were generated by CRISPR/Cas9 gene editing. BH3 profiling was used to measure the mitochondrial dependence of leukemia cells on anti-apoptotic BCL-2 family proteins. *In vivo* treatment of ABT-199 was performed in a set of three distinct ALL pdxs.
Results: Different sensitivities of ABT-199 were observed in a series of BCP-ALL pdxs and cell lines with heterogeneous anti-leukemia activities upon drug exposure. The majority of BCP-ALL samples showed sensitivity to ABT-199-induced cell death in the nanomolar range (EC50 <1µM) with four out of six cell lines and 20 of 27 pdxs, while ABT-199 insensitivities with EC50s of more than 1µM were identified in 26% of pdx leukemias. ABT-199 induces apoptosis by selectively inhibiting BCL-2 with a sub-nM binding-affinity thereby releasing pro-apoptotic molecules; however, the sequestration of drug-released BIM by anti-apoptotic MCL-1 might lead to resistance. Therefore, we investigated protein expression of both regulators and found the ratio (BCL-2/MCL-1) to be cor-

related with ABT-199 sensitivity (r_s=-0.71, p=0.008), highlighting the importance of simultaneous assessment of the direct target molecule and additional resistance mediating molecules. In line, MCL-1 knockout in two ABT-199-resistant cell lines led to sensitization towards ABT-199, however, resulted in different effects of sensitization, emphasizing that ABT-199 resistance is determined by the interplay of several apoptosis regulators. Therefore, we characterized the functional dependence of pdx leukemias on anti-apoptotic BCL-2 family members by BH3 profiling. Mitochondrial dependence on BCL-2 (mitochondrial priming by the BAD-peptide measuring BCL-2, BCL-XL and BCL-W, and subtracting the response to the HRK-peptide measuring BCL-XL) was found to be tightly correlated with ABT-199 sensitivity. In contrast, ABT-199-resistant samples were characterized by low BCL-2-dependence and addiction to other BCL-2 family members, including BCL-XL or MCL-1. Finally, we evaluated prediction of *in vivo* ABT-199 sensitivity in a pre-clinical ALL pdx mouse model by functional BH3 profiling. Strikingly, high mitochondrial BCL-2-dependency was clearly associated with prolonged leukemia-free survival upon ABT-199-therapy (two pdxs, log ranks p=0.0035 and <0.0001), in contrast to another leukemia with low BCL-2-dependence and *in vivo* ABT-199 resistance (log rank p=0.144).
Summary/Conclusions: BCP-ALL displays heterogenous ABT-199 sensitivities characterized by the level of the target molecule but also other interacting regulators. Functionally, mitochondrial BCL-2-dependence assessed by the BH3 profiling assay is clearly associated with ABT-199 sensitivity. Importantly, *in vivo* anti-leukemia activity of ABT-199 therapy in individual pdx leukemias is predicted by mitochondrial BCL-2 dependence, emphasizing the utility of identification of patients and guidance of future clinical application by functional assessment of apoptosis signaling.

CD45RA- MEMORY T CELLS EXPRESSING AN NKG2D-CAR TARGET PEDIATRIC ACUTE LEUKEMIA

L. Fernandez[1,*], J.-Y. Metais[2], J. Valentín[3], A. Escudero[4], M. Vela[3], A. Leivas[1], J. Martínez[1], W. Leung[5], A. Pérez-Martínez[6]
[1]Clinical Research, CNIO, Madrid, Spain, [2]Haematology, St.Jude Children´s Research Hospital, Memphis, United States, [3]Infectious diseases and Immunity, IdiPAZ, [4]Pediatric Oncology, INGEMM, Madrid, Spain, [5]Clinical Development, Miltenyi, Maryland, United States, [6]Pediatric Hemato-Oncology, Hospital Universitario La Paz, Madrid, Spain

Background: Lymphoid and myeloid acute leukemia are the most frequent type of cancer and the most frequent cause of cancer related death in children. Relapse and refractory disease are the main clinical problems that current therapies are still unable to solve. One of the main NK cell activating receptors is NK cell group 2D (NKG2D). NKG2D receptor recognizes human MICA, MICB and ULBP1-6 ligands. These NKG2D ligands (NKG2DL) are expressed in leukemia cells and constitute suitable targets for immunotherapy.
Aims: The aim of thi study was to analyze the NKG2DL expression on pediatric acute leukemia cells and determine their susceptibility to an NKG2D CAR cell based immunotherapy.
Methods: The expression of NKG2DL was analyzed in Peripheral Blood Mononuclear Cells (PBMCs) from patients suffering from acute leukemia, as well as in leukemia cell lines, by flow cytometry (FCM) using specific monoclonal antibodies directed against MICA, MICAB, ULBP-1, ULBP-2, ULBP-3 and ULBP-4, and by quantitative PCR using TaqMan probes. PBMC from healthy donors were labeled with CD45RA microbeads and depleted using AutoMACS device. The HL20i4r-MNDantiCD19bbz lentiviral vector was derived from the clinical vector CL20i4r-EF1a-hgcOPT27 but contained the extracellular domain of NKG2D, the hinge region of CD8a and the signaling domains of 4-1BB and CD3-z. The cassette was driven by MND promoter. Viral supernatant was produced by transient transfection of HEK293T cells with the vector genome plasmid and lentiviral packaging helper plasmids pCAGG-HIVgpco, pCAGG-VSVG and pCAG4-RTR2. Cytogenetic studies and array Comparative Genomic Hybridization were performed to analyze the genetic stability of lentiviral-transduced memory T cells. The *in vitro* cytotoxicity of CD45RA-NKG2DCAR+ memory T cells against leukemia cells, healthy PBMC and Mesenchymal Stem cells (MSC) was evaluated by performing conventional 4-hour europium-TDA release assays or by FCM using CFSE and 7AAD labeling of target cells.
Results: NKG2DL were heterogeneously expressed in leukemia primary cells and cell lines. For B cell ALL primary samples, we found expression of MICA/B, MICA and ULBP1 decreased in refractory disease compared to remission. Lentiviral transduction of NKG2D-4-1BB-CD3z increased NKG2D surface expression in CD45RA$^-$ memory T cells, which became consistently more cytotoxic than untransduced cells against leukemia cells. Additionally, no chromosomal aberrations nor cytotoxic activity against healthy PBMC or Mesenchymal Stem cells was observed in NKG2D CAR expressing T cells.
Summary/Conclusions: Our results show NKG2D-CAR redirected CD45RA$^-$ memory T cells target NKG2DL expressing leukemia cells *in vitro* and could be a promising and safe immunotherapeutic approach for pediatric acute leukemia patients.

P510

A BILINEAL ACUTE LYMPHOBLASTIC LEUKEMIA ORIGINATING AT A COMMON LYMPHOID PROGENITOR

A. Gonzalez-Murillo[1,*], C. Sánchez-Valdepeñas[1], C. Robledo[2], A. Castillo[1], L. Abad[1], C. Hernandez-Marques[1], D. Ruano[1], L. Madero[1], J. Alonso[2], M. Ramirez[1]
[1]Pediatric Hematology & Oncology, Hospital Universitario Niño Jesus, Madrid, [2]Instituto de Investigacion en Enfermedades Raras, Instituto de Salud Carlos III, Majadahonda, Spain

Background: Genetic mutations are crucial events during leukemogenesis and provide specific markers for backtracking the cellular origin of acute leukemias up to immature uni- or multi-potent progenitor cells in the hierarchy of the hematopoietic system.
Aims: To characterize the clonal architecture and cell of origin in a case of bilineal T- and B-ALL.
Methods: Bone marrow cells obtained at diagnosis were used for all studies. Immunophenotyping was done by flow cytometry. T- and B-leukemic cell purification was performed by immunomagnetics methods and DNA extracted afterward. TCR-gamma gene rearrangement was studied in T- and B-leukemic cells independently by PCR spectratyping. Somatic mutations in purified T- and B-leukemic cells were identified by deep-sequencing using a panel of 160 genes frequently mutated in cancer (Human comprehensive cancer panel, Qiagen). Mutations were validated by Sanger sequencing. Myeloid and erythroid clonogenic progenitors were isolated from methylcellulose cultures, DNA extracted, and assessed for the presence of the *H3F3A* p.K28N mutation by Sanger sequencing.
Results: The patient was a 10 years old boy. At diagnosis, the bone marrow was infiltrated by 60% leukemic cells, with 2 immunophenotypically different populations: a common B-ALL (54%) and a pro-T-ALL (6%). The patient showed a mediastinal mass in the chest X-ray image. A common TCR-gamma rearrangement was detected in purified (>95% pure) T-ALL and B-ALL cells, suggesting a common origin for both leukemic subpopulations. The B-ALL cells presented a c.35G>A p.G12D mutation in the *KRAS* gene, absent in the T-ALL. The T-ALL cells presented a c.35G>A (p.G12D) mutation in the *NRAS* gene, absent in the B-ALL. A c.1126_1127insTAGA (p.P376Lfs*10) mutation in the *WT1* gene was also detected only in the T-ALL. A c.84G>T (p.K28N) mutation in the *H3F3A* gene was detected in both the B-ALL and T-ALL subpopulations, confirming the involvement of a Common Lymphoid Progenitor in the process of leukemogenesis. The presence of the *H3F3A* p.K28N mutation in the myeloid compartment would point to a multipotent myeloid-lymphoid rather than a lymphoid-restricted progenitor as the cell origin of the leukemia. Therefore, we cultured myeloerythroid-committed progenitor cells in clonogenic cultures and sequenced the *H3F3A* gene. None of the 122 myeloid or erythroid clonogenic progenitors (41 CFU-GM, 73 BFU-E and 8 CFU-GEMM) presented the p.K28N mutation in the *H3F3A* gene.
Summary/Conclusions: Our results indicate the involvement of a Common Lymphoid Progenitor as the cell of origin in this case of bilineal ALL, as well as the crucial role of *H3F3A* and *RAS* family genes in the leukemogenesis process coupled with B and T differentiation.

P511

CYSTEINE AND GLYCINE-RICH PROTEIN 2 (CSPR2) TRANSCRIPT LEVELS CORRELATE WITH LEUKEMIA RELAPSE AND LEUKEMIA-FREE SURVIVAL IN ADULT B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA WITH NORMAL CYTOGENETICS

S.-J. Wang[1,*], P.-Z. Wang[2], R. Gale[3], Y.-Z. Qin[1], Y.-R. Liu[1], Y.-Y. Lai[1], H. Jiang[1], Q. Jiang[1], X.-H. Zhang[1], B. Jiang[1], L.-P. Xu[1], X.-J. Huang[4], K.-Y. Liu[1], G.-R. Ruan[1]
[1]Peking University Peoples Hospital and Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, [2]Department of Immunology, School of Basic Medical Sciences, Peking University Health Science Center., Beijing, China, [3]Haematology Research Center, Division of Experimental Medicine, Department of Medicine, Imperial College London, London, United Kingdom, [4]Peking University Peoples Hospital and Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation,Peking-Tsinghua Center for Life Sciences, Beijing, China

Background: Outcome of adults with B-cell acute lymphoblastic leukemia (ALL) remains poor and relapse is the major cause of treatment-failure. Identifying new biomarkers in B-cell ALL especially in those with normal cytogenetics and studying their clinical significance and biological function will be helpful for risk-stratification, treatment decision and targeted therapy.CSRP2 (cysteine and glycine rich protein 2) maps to chromosome subband 12q21.1, which is frequently abnormal in diverse cancers. Increased CSRP2 transcript levels are associated with de-differentiation in hepatocellular carcinoma and CSRP2 is proved to be a new invadopodia actin bundling factor that critically promotes breast cancer cell invasion and metastasis. However, the clinical significance and biological function of CSRP2 in B-cell ALL remains unknown.

Aims: To identify novel biomarkers in B-cell ALL based on bioinformatics analyses; to examine the expression and clinical significance of CSRP2 in adults with B-ALL; to explore effects of CSRP2 on biological function of B-cell ALL.
Methods: We did bio-informatics analyses to identify mRNA transcripts aberrantly-expressed in B-cell ALL. RT-qPCR (real-time quantitative polymerase chain reaction) was used to examine CSRP2 transcript levels in bone marrow samples from 236 adults with B-cell ALL compared with samples from normal. A prognostic value was assessed in 168 subjects. CSRP2-knockdown and CSRP2-over-expression cell models were constructed to study the biological function of CSRP2 in B-cell ALL.
Results: We selected 9 candidate genes for validation 7 of which proved significantly-associated with B-cell ALL. CSRP2 was the most differentially expressed gene in our validation studies. CSRP2 was over-expressed in 228 out of 236 adults (97%) with newly-diagnosed B-cell ALL. In subjects with normal cytogenetics those with high CSRP2 transcript levels had a higher 5-year cumulative incidence of relapse (CIR) and worse relapse-free survival (RFS) compared with subjects with low transcript levels (56% [95% confidence interval 53-59%] *vs* 19% [18- 20%]; *P*=0.011 and 41% [17-65%] *vs* 80% [66-95%]; *P*=0.007). In multivariate analyses a high CSRP2 transcript level was independently-associated with CIR (HR=5.32 [1.64-17.28]; *P*=0.005) and RFS (HR=5.56 [1.87-16.53]; *P*=0.002). Functional analyses indicated CSRP2 promoted cell proliferation, cell-cycle progression, *in vitro* colony formation and migration. Abnormal CSRP2 expression was associated with resistance to chemotherapy; sensitivity was restored by down-regulating CSRP2 expression. CSRP2 activated ERK1/2 signaling pathway, regulated cell-cycle related protein and activated CREB signaling pathway, whose activation was associated with poor prognosis in adults with B-cell ALL.
Summary/Conclusions: CSRP2 was widely over-expressed in adults with B-cell ALL. Determination of CSPR2 transcript levels in subjects with normal cytogenetics might inform therapy-decisions. Consideration could be given to down-regulating CSPR2 expression as a way to reverse drug resistance.

P512

THERAPEUTIC TARGETING OF PRE-B CELL RECEPTOR SIGNALLING IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

A. Alhammer[1,2,*], M. Case[1], E. Matheson[1], H. Blair[1], J. Vormoor[1], J. Irving[1]
[1]Newcastle University, Northern Institute for Cancer research, Newcastle upon Tyne, United Kingdom, [2]Al-Nahrain University, Biotechnology research Center, Baghdad, Iraq

Background: Acute lymphoblastic leukaemia (ALL) is the most common malignancy in children and adolescents and relapsed ALL remains one of the leading causes of cancer-related deaths in children. Components of the precursor-B cell receptor (Pre-BCR) signalling pathway are hijacked in ALL cells and this dependence may be therapeutically targeted. A number of tyrosine kinase inhibitors (TKIs) targeting effectors of this signalling pathway are showing great promise in the clinic and warrant preclinical evaluation in paediatric ALL. They include Dasatinib (BCR-ABL/SRC inhibitor), Fostamatinib R406 (SYK inhibitor), Ibrutinib (BTK inhibitor) and CAL-101 (PI3K-δ inhibitor).
Aims: To preclinically evaluate these candidate TKIs, as novel, targeted drugs for high risk and relapsed ALL.
Methods: ALL cell lines (Reh, Nalm-6, PreB 697 and its glucocorticoid resistant descendant, R3F9) and 36 primary-derived xenograft (PDX) cells from 16 ALL were used in the study. Cell viability was assessed by Resazurin. Pre-BCR expression (μHc, Vpreb and λ5) and functionality using a Calcium flux assay were detected by Flow cytometry. Intracellular phospho-flow cytometry was used to detect constitutive phosphorylation and activation in response to anti-Igμ antibody, as well as drug pharmacodynamic measures (p-BTK, p-SYK, p-AKT, p-ERK, p-PLC-Y2, p-BLNK). Apoptosis and cell cycle were analysed by flow cytometry using Annexin V and Propidium Iodide. RQ-PCR was used to measure *GILZ* expression. Bim induction, GR expression and phosphorylation were detected by western blotting.
Results: ALL cell lines were modestly sensitive to Dasatinib (mean GI50 5.33 μM, range 2.45 μM-12.5 μM) and R406 (mean GI50 4.32 μM, range 2.88 μM-5.83 μM). However, cells were resistant to Ibrutinib (mean GI50 15.9 μM, range 11.47 μM-18.3 μM) and CAL-101 (mean GI50 52.08 μM, range 25 μM-77.83 μM). Cell cycle arrest and significant apoptosis was seen with R406 and Ibrutinib treatment, while Dasatinib and CAL-101 were cytostatic, causing G1 arrest with no substantial cell death. Pharmacodynamic assays confirmed inhibition of the relevant drug targets. PDX cells showed greater sensitivity than the cell lines to Dasatinib (4 out of 16 patient samples <0.5μM), R406 (7 out of 16 patient samples <5μM), Ibrutinib (3 out of 15 patient samples <5μM) and CAL-101 (3 out of 15 patient samples <2μM). Pre-BCR positive ALL cell lines and PDX cells were sensitive to R406 and Dasatinib, with a Ph+ PDX confirming sensitivity to the latter. Combining TKIs with the glucocorticoid (GC), Dexamethasone showed synergism in ALL cell lines and was particularly notable for Dasatinib and R406 in PreB cell receptor positive lines. Synergism was associated with significantly enhanced apoptosis, an increase in expression of the GR target gene, *GILZ* and for Dasatinib, enhanced expression of the pro-apoptotic, Bim. Control REH cells (GC receptor negative) showed no synergism.
Summary/Conclusions: Significant sensitivity of TKIs targeting Pre-BCR signalling have been identified at clinically achievable concentrations. Dasatinib and R406 sensitivity was associated with Pre-BCR positive ALL and combination with Dexamethasone showed significant synergism in GC resistant cell lines and PDX samples. TKIs were also effective in some Pre-BCR negative ALL cells, however, predictive biomarkers need to be established. Confirmation of these data in preclinical models *in vivo* may define new therapies for high risk ALLs.

P513

BMP-4 LEVELS IN CHILDHOOD B-ALL OF LOW-/INTERMEDIATE-RISK GROUPS IDENTIFY CHILDREN WITH POOR OUTCOME

L.M. Fernández-Sevilla[1,*], C. Sánchez-Valdepeñas[2], A. Gonzalez-Murillo[2], A. Entrena[1], C. Martinez-Laperche[2], G. Melen[2], A. Varas[1], A. Vicente[1], M. Ramirez[2]

Background: Leukemic relapses among children with acute lymphoblastic leukaemia (ALL) from low/intermediate-risk groups is a challenge for the cure of this disease. New biomarkers are needed for identifying children at high risk of relapses. Bone Morphogenetic Proteins (BMPs) are multifunctional secreted growth factors that belong to the TGF-β superfamily and are well-known for their indispensable roles in vertebrate development. In the cellular context, BMPs regulate fundamental processes such as cell proliferation, differentiation, migration and survival. In last years, important new information has been generated on the contribution of BMP family members, such as BMP4, in cancer pathogenesis.
Aims: Here we have evaluated the relevance of BMP4 signaling in ALL.
Methods: The expression levels of BMP-4 related genes (bmp-4, and bmp-receptors, signaling mediators, inhibitors and targets) in ALL blasts obtained at the time of diagnosis (n=56), and the BMP-4 levels in central system fluid samples (CSF), were quantitated by RT-qPCR or ELISA. The engrafting potential of primary ALL cells, exhibiting high or low BMP4 levels, were assessed in xenotransplantation experiments using unirradiated NSG mice.
Results: BMP4 was expressed at significantly higher levels in ALL blasts of children who later relapsed (178,78 *versus* 26,68, arbitrary units, AU, p<0,05). Relapses among children with high BMP-4 expression occured significantly later than those with low BMP-4 expression (845 days *versus* 282 days, p<0,05). The difference in the cumulative incidence of relapses (CIR) was quasi-significant between both groups (p=0,0831). The ratio Smad7:Smad1, suggesting inhibition of the Smad-dependent signaling pathway, was significantly higher in ALL blasts of children who later relapsed (14,33 *versus* 5,13, AU, p<0,05). CIR was significantly higher (p<0,05) in the group of children with the Smad-dependent pathway inhibited. All these differences were detected considering the whole population, as well as only the low/intermediate-risk groups. BMP4 levels were significantly higher in CSF samples of children with leukemic infiltration of the central nervous system (16pg/ml *versus* 3,4pg/ml, p<0,001), as well as in the group of children who relapsed (10,6 pg/ml *versus* 1,8 pg/ml, p<0,001). Hematopoietic engraftment (marrow, spleen and peripheral blood) and CNS leukaemia occured only in ALL samples with high BMP4 levels. Even more, no signs of disease were detected in mice transplanted with primary cells which expressed low levels of BMP4. In independent experiments, pharmacological blockade of the canonical BMP signaling pathway significantly decreased infiltration of CNS and consistently resulted in amelioration of clinical parameters including neurologic score.
Summary/Conclusions: These results indicate that high BMP4 levels are required for both bone marrow engraftment and CNS infiltration by B-ALL cells. BMP4 levels in leukemia cells could be a useful biomarker to identify children with poor outcome in the childhood B-ALL of low-/intermediate-risk groups. Furthermore, BMP4 could be a new therapeutic target to blockade leukemic CNS disease.

P514

TARGETING LOCALIZATION OF THE IL-7 RECEPTOR WITHIN LIPID RAFTS AS A THERAPEUTIC STRATEGY FOR T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

A. Buffière[1,*], C.-H. Nguyen[2], B. Uzan[3], J.-N. Bastie[14], L. Delva[1], F. Pflumio[3], R. Quéré[1]
[1]Signaling And Physiology In Hematological Research, UMR1231 Inserm, Université Bourgogne Franche-Comté, AgroSup, Dijon, [2]Institut Curie, PSL Research University, UMR9187 U1196, CNRS-Institut Curie, Inserm, Centre Universitaire, Orsay, [3]Commissariat à l'Energie Atomique et aux Energies Alternatives (CEA), DSV-IRCM-SCSR-LSHL, Inserm UMR 967, Fontenay-aux-Roses, [4]Clinical Hematology Department, François Mitterand University Hospital, Dijon, France

Background: T-cell acute lymphoblastic leukemia (T-ALL) is a hematological malignancy characterized by immature T-cell excessive proliferation. To achieve remission, patients typically undergo 2 years of chemotherapy, associated with acute and chronic side effects. To enable reduced chemotherapy intensity and

treat relapsed patients, there is still a need to develop new and effective targeted therapies. Previous evidence has shown IL-7 as a fundamental cytokine for normal T-cell development and homeostasis, as well as an important determinant for the T-ALL cell viability and proliferation *in vitro* and *in vivo*. Several strategies have been explored for the treatment of T-ALL, and targeting Interleukin 7 receptor alpha-chain (IL-7Rα) and downstream IL-7 signaling offers a potentially effective therapeutic strategy for T-ALL. The IL-7Rα is recruited and concentrated into lipid rafts thereby amplifying its downstream signaling pathway. The IL-7/STAT5 signaling pathway mediates downregulation of pro-apoptotic signals on human T-cells such as BAD and BIM. Moreover, we have previously reported that a new compound named Pyrido[4,3-b]Quinoxaline (PyQ) has an anti-tumoral effect on Acute Myeloblastic Leukemia (AML). It strongly interacts with the plasma membrane of AML cells and affects the positioning of the protein tyrosine phosphatase CD45, which is usually organized in microdomains into lipid rafts floating on the cell surface, and is delocalized by PyQ.

Aims: The aim of this study was to assess the anti-tumoral effect of PyQ on T-ALL cells and to identify which signaling pathway is affected by the compound.

Methods: We have 2 models of human T-ALL which can be studied *in vitro* when cocultured with murine stromal MS5 cells and *in vivo* when transplanted into immunodeficient NOD/SCID/γc−/− (NSG) mice. We also work on primary T-ALL blasts isolated from 10 patients suffering of T-ALL and maintained frozen in a biobank.

Results: In this study, we have shown that PyQ delocalizes the IL-7Rα away from lipid rafts on the cell surface of human T-ALL cells. We have also proved that localization of the IL-7Rα among lipid rafts plays a crucial role in human T-ALL maintenance *in vitro*. Its delocalization leads to IL-7 signaling pathway inactivation, upregulation of BAD and BIM genes involved in apoptosis and T-ALL cells apoptosis. We furthermore assessed effect of PyQ on 10 samples of primary T-ALL blasts. All of them were sensitive to IL-7-dependent cell survival and revealed a marked response to PyQ treatment (Mean IC_{50}=5.7 ng/mL). For this work, T-ALL cells were co-cultured on murine stromal MS5 cells and PyQ has affected mainly T-ALL cell growth. No effect was observed on the stromal feeder cells, suggesting that injection of PyQ *in vivo* would not impact the stromal microenvironment in bone marrow. Finally, we provided evidence that PyQ delayed T-ALL progression *in vivo*, after treatment of immunodeficient mice xenografted with T-ALL cells.

Summary/Conclusions: The findings of this study highlight the importance of the IL-7Rα localization in maintenance of T-ALL cells and may lead to the design of a new generation of anti-cancer drugs able to modulate the protein positioning into lipid rafts.

Acute lymphoblastic leukemia - Clinical 2

SYSTEMATIC MRI SCREENING IDENTIFIES EXTENSIVE ASYMPTOMATIC OSTEONECROTIC LESIONS IN ADOLESCENTS WITH ALL - FIRST INTERIM FINDINGS OF THE OPAL TRIAL

M. Kuhlen[1,*], M. Kunstreich[2], K. Krull[1], J. Klasen-Sansone[3], F. Schramm[4], G. Escherich[4], A. Moericke[5], M. Schrappe[5], D. Klee[3], A. Borkhardt[1]

[1]Department of Pediatric Oncology, Hematology and Clin. Immunology, University Children´s Hospital, Medical Faculty, Heinrich Heine University, [2]Department of Pediatric Oncology, Hematology and Clin. Immunology, University Children´s Hospital, Medical Faculty, Heinrich Heine University Duesseldorf, [3]Department of Diagnostic and Interventional Radiology, Medical Faculty, Heinrich Heine University, Duesseldorf, [4]Clinic of Pediatric Hematology and Oncology, University Medical Centre Hamburg-Eppendorf, Hamburg, [5]Department of Pediatrics, University Medical Centre Schleswig-Holstein, Campus Kiel, Kiel, Germany

Background: Cure rates for acute lymphoblastic leukemia (ALL) have increased to ~90% in the last decades, but come at a high cost as a substantial proportion of these children sustain toxic side-effects. Osteonecrosis (ON) is one of the most common and debilitating side effects, which severely impacts quality of life.

Aims: To analyze whether systematic magnetic resonance imaging (MRI) screening of adolescents can identify those with asymptomatic ON (stage I and II), who subsequently develop symptomatic ON.

Methods: Children diagnosed with ALL aged ≥10 years, who were enrolled in the ongoing prospective multicenter OPAL (osteonecrosis in pediatric patients with ALL or lymphoblastic lymphoma LBL) trial, were analyzed. Standardized MRI screening of the hips and knees was scheduled at diagnosis and 6, 9, 12, 15, 18 and 24 months into treatment. All patients were assessed according to a standardized case report form recording symptoms and activities of daily living and functional impairments of the hips and knees based on modified Harris Hip and Knee Society scores every 3 months from diagnosis to the end of antileukemic treatment.

Results: Between 03/2013-12/2016, 64 patients (pts) were enrolled, median age at ALL diagnosis was 15 years (range 10-17), median time under evaluation was 11 months (range 0-45). 31 (48.4%) pts were male, 33 (51.6%) female. 61 (95.3%) were diagnosed with ALL, 3 (4.7%) with LBL. 36 (56.2%) pts were treated according to the AIEOP-BFM 2009 trial, 25 (39.1%) pts to the CoALL-08-09 trial and 3 (4.7%) pts were enrolled in the NHL-BFM registry and treated accordingly. Until December 31st, 2016, 2 (3.1%) pts died treatment related, 4 (6.3%) underwent allogeneic stem cell transplantation, and 5 (7.8%) pts each relapsed while under treatment and dropped out for other reasons. Thus, so far, 166 MRIs comprising 664 joints could be evaluated. At initial diagnosis of the leukemia, MRI showed asymptomatic osteonecrotic lesions stage II or higher in 3 of 60 pts (5%), at 6 months in 7 of 34 pts (20.6%) osteonecrotic lesions, at 9 months in 14 of 23 pts (60.9%), at 12 months in 14 of 23 pts (60.9%), at 15 months in 3 of 11 pts (27.3%), at 18 months in 2 of 9 pts (22.2%), and at the end of treatment in 2 of 6 pts (33.3%). 11 (17.2%) pts developed symptomatic ON between 6 and 15 months from diagnosis (median 10 months). Of 23 pts, in whom screening MRI revealed ON stage II or higher, 11 pts (47.8%) subsequently developed symptomatic ON whereas in all adolescents developing symptomatic ON MRI had previously shown signs of ON. Median volumes of epiphyseal necrosis in pts with ON stage II remaining asymptomatic were 0.6 ml (range 0.1-7.2) and in pts developing symptomatic ON 12.5 ml (range 12.0-13.9) in the hips and 2 ml (range 0.4-20.5) and 30.5 ml (range 18.3-57) in the knees respectively. Epiphyseal involvement exceeded 30% in all symptomatic pts, but only in 2 pts remaining asymptomatic. With regard to the distribution pattern of ON, about twice as many knees as hips were affected by ON stage II or higher. MRI revealed ON stage III or higher in at least one joint in 12 pts (20%), predominantly in the knees. Radiological leukemic infiltration of bone detected by single screening MRI at diagnosis did not identify children at high risk of developing asymptomatic ON at six months into therapy or symptomatic ON anytime in the course of antileukemic treatment. These findings should be confirmed in larger patient numbers.

Summary/Conclusions: The first analysis of the OPAL trial shows that early MRI screening identifies extensive asymptomatic lesions in adolescents subsequently developing symptomatic ON.

Background: Front-line imatinib (IM) plus chemotherapy followed by allogeneic hematopoietic stem cell transplantation (HSCT) is standard therapy for patients (pts.) with Ph+ ALL. Relapse after HSCT remains a major cause of treatment failure, and pts. in whom *BCR-ABL* transcripts are detectable after HSCT are at particular risk. Posttransplant maintenance using tyrosine kinase inhibitors (TKIs) to reduce the relapse rate remains a subject of uncertainty, as data from prospective studies are limited.
Aims: To determine the impact of IM administration after HSCT on patient outcome and assess the predictive value of minimal residual disease (MRD) analysis by qRT-PCR of BCR-ABL1 transcripts.
Methods: In this prospective, multicentre trial by the GMALL study group, adult pts. (≥ 18 y) with Ph+ ALL in CR at HSCT were randomly assigned (1:1) to receive IM prophylactically after SCT or pre-emptively upon detection of MRD. Inclusion criteria included engraftment, sufficient hematopoietic and organ function, no uncontrolled GVHD or infections. Target dose of IM was 600mg/d, 400mg recommended as starting dose. Primary endpoint was molecular or hematologic relapse, secondary endpoints included survival, DFS, severe toxicity and transplant-related mortality. All pts. were followed by frequent serial MRD analysis after HSCT. An interim analysis was reported previously. We here provide results of the final analysis of this trial, with long-term follow-up of up to 11 years after HSCT.
Results: 74 pts. were evaluable, 36 received prophylactic and 38 pts. pre-emptive IM. Median age was 41 y (18-69) and 44 y (19-68), respectively. Disease status at HSCT was CR1 (n= 67), CR2 (n=5), CR3 (n=1), unknown (n=1). Most pts. received a PBSC graft (n=71) and myeloablative TBI-based conditioning (n=65), 8 pts. underwent RIC with 2Gy or 4Gy TBI (n=6) or non-TBI RIC (n=2). Median time from HSCT to starting IM was 48d and 77d, respectively. IM dose was 600mg/d in 22% of pts., remaining pts. received 400mg. Treatment was prematurely discontinued in 56% and 59% of pts., median time to discontinuation was 251d and 192d. Median follow-up of surviving pts. is 5.6 y (2.4-10.8) and 6.9 y (1.8-11). Relapse rate (14% *vs.* 18%), NRM (12% *vs.* 11%) and ongoing CR (69% *vs.* 71%) were not significantly different between arms. Probability of DFS and overall survival at 10 years was 64% *vs* 69% and 68% *vs* 71% with prophylactic and pre-emptive IM, respectively (p=ns). MRD levels were significantly predictive of relapse: BCR-ABL1/ABL1 (B/A) ratio $\geq 10^{-3}$ within 6 weeks prior to HSCT was associated with a higher cumulative incidence of relapse (CIR) at (47.5% *vs* 10.6%, p=0.006) and inferior DFS (45% *vs* 79%, p=0.027) at 10y. B/A ratio $\geq 10^{-4}$ within 100d after HSCT was likewise associated with a higher CIR (45% *vs* 13%, p=0.0046) and inferior DFS (55% *vs* 71%, p=0.054) at 8 y. An algorithm combining pre- and early (<100 days) post-transplant MRD levels (pre: $\geq 10^{-3}$; post: any positivity including below quantitative range) identified patients with a 60% *vs* 8.5% CIR at 10 y.
Summary/Conclusions: Post-HSCT intervention with prophylactic or pre-emptive IM is associated with a low relapse risk and excellent long-term survival and might be considered standard of care in Ph+ ALL pts. undergoing HSCT. BCR-ABL1 transcript levels prior to and early after SCT are predictive of outcome and identify a small subset of patients unlikely to benefit, emphasizing the need for rigorous MRD monitoring. The identified MRD thresholds should be validated in an independent dataset. Their applicability in the setting of RIC transplant or 2nd/3rd G TKI remain to be determined.

P517

ANALYSIS OF SAFETY DATA FROM 2 MULTICENTER TRIALS OF CTL019 IN PEDIATRIC AND YOUNG ADULT PATIENTS WITH RELAPSED/ REFRACTORY (R/R) B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL)

Background: The CD19-targeted chimeric antigen receptor (CAR) T-cell therapy CTL019, an investigational therapy that uses reprogrammed cytotoxic T cells to recognize and eliminate target cells, has shown high response rates in clinical trials for pediatric/young adult R/R B-ALL. The safety profile in this population has been limited to a single-center trial.
Aims: To identify any new safety issues with CTL019 emerging from use in multicenter trials.
Methods: Pooled data from 2 single-arm, multicenter phase 2 trials of CTL019 therapy in pediatric/young adult patients (pts) with R/R B-ALL (NCT02435849 and NCT02228096) were used to further characterize the safety of CTL019.

Table 1.

Table. Selected Adverse Events Post CTL019 Infusion

Adverse event, n (%)	Patients (N = 97)	
CRS	79 (81.4)	
Median time to onset (range), days	3 (1-22)	
Median duration (range), days	8 (1-36)	
Admitted to ICU	43 (44.3)	
Median duration of ICU stay (range), days	8 (1-34)	
Anticytokine therapy	33 (34.0)	
High-dose vasopressors	26 (26.8)	
Intubated	16 (16.5)	
Dialyzed	11 (11.3)	
	All grades	Grade 3/4
Grade 3/4 neutropenia with high fever	NA	59 (60.8)
Infections (>3%)	43 (44.3)	21 (21.6)
Staphylococcal infection	5 (5.2)	2 (2.1)
Clostridium difficile	4 (4.1)	3 (3.1)
Conjunctivitis	4 (4.1)	0
Rhinovirus	4 (4.1)	0
Candida	3 (3.1)	1 (1.0)
Clostridium difficile colitis	3 (3.1)	0
Pneumonia	3 (3.1)	2 (2.1)
Staphylococcal bacteraemia	3 (3.1)	3 (3.1)
Neuropsychiatric events (>3%)	39 (40.2)	11 (11.3)
Confusional state	12 (12.4)	0
Encephalopathy	9 (9.3)	4 (4.1)
Delirium	8 (8.2)	3 (3.1)
Agitation	6 (6.2)	0
Tremor	6 (6.2)	0
Irritability	5 (5.2)	0
Hallucination	4 (4.1)	0
Somnolence	4 (4.1)	1 (1.0)
Cognitive disorder	3 (3.1)	1 (1.0)
Lethargy	3 (3.1)	0
Seizure	3 (3.1)	1 (1.0)
Cytopenias not resolved by day 28	34 (35.1)	29 (29.9)
White blood cell count decreased	12 (12.4)	10 (10.3)
Platelet count decreased	11 (11.3)	8 (8.2)
Anemia	9 (9.3)	5 (5.2)
Neutrophil count decreased	9 (9.3)	7 (7.2)
Thrombocytopenia	9 (9.3)	8 (8.2)
Lymphocyte count decreased	6 (6.2)	4 (4.1)
Tumor lysis syndrome	3 (3.1)	3 (3.1)

Results: 123 pts were enrolled, 26 were not infused and not included in this analysis (10 deaths, 9 manufacturing failures, 3 adverse events [AEs], 4 pts pending infusion). 97 pts received a single infusion of transduced CTL019 cells (median dose, 3.2×10^6 [range, $0.2\text{-}5.4\times10^6$] cells/kg). Median age was 12y (range, 3-25). During the first 8 wk after infusion, 98% of pts experienced an AE of any grade (G), 82% experienced G3/4 AEs, and 72% experienced a serious AE (SAE). Common nonhematologic G3/4 AEs (≥10%) during the first 8 wk were cytokine release syndrome (CRS; 44%), hypotension (24%), decreased appetite (21%), increased AST (19%) and ALT (12%), hypoxia (16%), hypokalemia (13%), hypophosphatemia (11%), and pulmonary edema (10%). Rates of G3/4 AEs and SAEs decreased substantially >8 wk post infusion (41% and 24%, respectively). 21 pts died post infusion: 16 (76%) from B-ALL (n=2, ≤30 days after infusion; n=14, >30 days); cerebral hemorrhage (n=1) and embolic infectious stroke (n=1) (both ≤30 days); and infection (n=3, >30 days). Safety events were similar across pt subgroups based on age, sex, prior allogeneic stem cell transplant (alloSCT) (n=57), and Down syndrome (n=7). CRS, graded on the UPenn scale, occurred in 81% of pts (**Table 1.**). All CRS events occurred <8 wk post infusion. CRS was managed with supportive care, and 34% of pts were treated with anti-IL-6 agents. No deaths were attributed to CRS. Pts with ≥50% bone marrow (BM) blasts at enrollment (n=68) were

twice as likely to develop G3/4 CRS than pts with <50% BM blasts (n=29) (53% *vs* 24%). Earlier-onset fever correlated with severity of CRS. CRS grade correlated with serum IL-6 levels. CRS-associated coagulopathy with fibrinogen levels <1.0 g/L was observed in 10% of pts. Neuropsychiatric AEs occurred during or shortly after CRS resolution, were self-limiting, and were more likely in pts with severe CRS or history of CNS leukemia or other CNS diseases. No G4 neuropsychiatric events were observed. Other AEs of special interest within the first 8 wk included G3/4 neutropenia with high (>38.3˚C) fever (61%) and infections (G3/4, 22%). Prolonged G3/4 neutropenia (not resolved >28 days) occurred in 59 pts (61%). 36% of pts with prolonged G3/4 neutropenia had G3/4 infections after day 28. One pt with prior alloSCT was diagnosed with unconfirmed gut GVHD. Responding pts developed prolonged B-cell aplasia that was managed with immunoglobulin replacement. Tumor lysis syndrome was uncommon (3%).

Summary/Conclusions: This pooled analysis of global experience with CTL019 across 25 sites and 11 countries found no new safety issues. CRS and neuropsychiatric events, which are class effects of CAR T-cell therapy, were effectively managed. CTL019 appears similarly safe in pts with Down syndrome or prior alloSCT and across age groups. Prolonged follow-up will be required to determine the long-term safety of B-cell aplasia.

P518

UPDATED RESULTS OF A PHASE II STUDY OF HYPER-CVAD PLUS PONATINIB AS FRONTLINE THERAPY FOR ADULTS WITH PHILADELPHIA CHROMOSOME-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA

N. Short[1,*], H. Kantarjian[1], F. Ravandi[1], N. Daver[1], N. Pemmaraju[1], D. Thomas[1], M. Yilmaz[1], T. Kadia[1], K. Sasaki[1], R. Garris[1], G. Garcia-Manero[1], C. DiNardo[1], M. Konopleva[1], Z. Estrov[1], N. Jain[1], W. Wierda[1], V. Jeanis[1], J. Cortes[1], S. O'Brien[2], E. Jabbour[1]
[1]The University of Texas MD Anderson Cancer Center, Houston, [2]The University of California - Irvine, Orange, United States

Background: Ponatinib is a third-generation pan-BCR-ABL inhibitor that is effective in Philadelphia chromosome-positive (Ph+) acute lymphoblastic leukemia (ALL) and overcomes the T315I gatekeeper mutation.
Aims: We designed a phase II trial to evaluate the efficacy and safety of hyper-CVAD plus ponatinib in adults with newly diagnosed Ph+ ALL.
Methods: Adults with newly diagnosed Ph+ ALL received 8 cycles of hyper-CVAD alternating with high dose MTX/Ara-C every 21-28 days, as permitted by peripheral count recovery. Patients (pts) who had received 1-2 courses of prior chemotherapy with or without other TKIs were still eligible. Ponatinib was given at 45mg daily on days 1-14 of cycle 1. Initially, pts then received ponatinib 45mg daily continuously beginning with cycle 2. Due to concern for potential cardiovascular toxicity with ponatinib, after 39 pts had been treated, the protocol was amended so that, beginning in cycle 2, pts in CR received ponatinib at a dose of 30mg daily and pts in complete molecular response (CMR) received 15mg daily. Rituximab was given during the first 4 cycles in pts with CD20 expression ≥20%; all pts received IT chemotherapy prophylaxis with the first 4 cycles. Pts in CR after 8 cycles of hyper-CVAD received maintenance with ponatinib, vincristine and prednisone for 2 years followed by indefinite daily ponatinib.
Results: To date, 64 pts have been treated; 10 pts had received prior treatment at the time of enrollment, 8 of whom were in CR and 2 of whom were not in CR. Median age was 48 years (range, 21-80 years). 23 pts (36%) were positive for CD20 expression. *BCR-ABL1* transcript was p190 in 45 pts (70%), p210 in 18 (28%) and unknown in 1 (2%). Of 56 pts not in CR at the time of study enrollment, 100% achieved CR; all but 1 pt achieved CR after the first cycle. The complete cytogenetic response rate was 98%, major molecular response (MMR) rate was 97% and CMR rate was 77%. The median time to MMR was 3 weeks (range, 2-14 weeks), and the median time to CMR was 10 weeks (range, 2-96 weeks). The median follow-up was 33 months (range, 2-62 months), and median number of cycles received was 6 (range, 2-8 cycles). 10 pts (16%) underwent allogeneic stem cell transplantation (ASCT) in first remission. Overall, 8 pts have relapsed (3 while still on ponatinib, 3 while on another TKI, 1 while not receiving a TKI, and 1 after ASCT). 14 pts have died, 8 of whom were in CR. Two deaths were attributed to ponatinib (both from MI while in CR). 38 pts are still receiving treatment (consolidation, n=7; maintenance, n=14; post-maintenance TKI, n=17). The 3-year continuous CR and OS rates were 79% and 76%, respectively. In a 4-month landmark analysis to assess the impact of ASCT, continued CR and OS did not differ according to whether ASCT was performed in first remission. Treatment was overall well-tolerated. Myelosuppression was as anticipated with hyper-CVAD-based therapy, with median times to platelet and ANC recovery in cycle 1 of 22 days (range, 17-35 days) and 18 days (range, 13-29 days), respectively. In cycles 2-8, the median times to platelet and ANC recovery were 22 days and 16 days, respectively. Grade ≥3 adverse events included pancreatitis in 12 pts (19%), hypertension in 8 (13%), thrombotic events in 4 (6%) and MI in 3 (5%). No grade ≥3 cardiovascular events have occurred after the protocol amendment with ponatinib dose reductions.
Summary/Conclusions: Hyper-CVAD plus ponatinib is effective in patients with newly diagnosed Ph+ ALL, resulting in a CMR rate of 77% and encouraging long-term survival.

P519

PROGNOSTIC IMPLICATIONS OF PRETREATMENT CYTOGENETICS IN ADULTS WITH RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH INOTUZUMAB OZOGAMICIN

E. Jabbour[1,*], A. Advani[2], M. Stelljes[3], W. Stock[4], M. Liedtke[5], N. Gökbuget[6], G. Martinelli[7], S. O'Brien[8], J. Liang White[9], T. Wang[9], M.L. Paccagnella[9], B. Sleight[9], E. Vandendries[10], D.J. DeAngelo[11], H.M. Kantarjian[1]
[1]MD Anderson Cancer Center, Houston, [2]Cleveland Clinic, Cleveland, United States, [3]University of Muenster, Muenster, Germany, [4]University of Chicago, Chicago, [5]Stanford Cancer Institute, Stanford, United States, [6]Goethe University, Frankfurt, Germany, [7]Institute Seràgnoli, DIMES, University of Bologna, Bologna, Italy, [8]University of California, Irvine, Orange, [9]Pfizer Inc, Groton, [10]Pfizer Inc, Cambridge, [11]Dana-Farber Cancer Institute, Boston, United States

Background: In the phase 3 INO-VATE study of relapsed/refractory acute lymphoblastic leukemia (R/R ALL) patients, inotuzumab ozogamicin (InO) showed improved complete remission or complete remission with incomplete hematologic recovery (CR/CRi) rates *versus* standard care (SC; 80.7% *vs* 29.4%; *P*<0.001) (NCT01564784; Kantarjian *NEJM* 2016 [data cutoff date: Oct 2, 2014]).
Aims: To assess the impact of baseline karyotype on response and toxicities in R/R ALL patients receiving InO from the INO-VATE study
Methods: Full study details have been previously published. At screening, karyotyping was performed locally; ≥20 metaphase count was recommended for cytogenetic analysis. Karyotypes were interpreted using the International System for Cytogenetic Nomenclature. CR/CRi and minimal residual disease (MRD) negativity rates (defined as <0.01% bone marrow blasts as assessed at a central laboratory) were compared using a chi-square test or Fisher exact test. Survival estimates were compared using a log-rank test. Data as of March 8, 2016, are presented. Informed consent was obtained from all patients. All analyses presented were not adjusted for multiple testing.
Results: Of 326 patients randomized, 284 had cytogenetic data at screening (InO: 144; SC: 140). Of 164 InO-treated patients, 21.3% had normal diploid karyotype (≥20 metaphases), 17.1% complex (≥5 abnormalities), 13.4% Philadelphia-chromosome positive (Ph+) disease, 6.7% diploid (<20 or unknown metaphases), 4.9% hyperdiploidy >50, 4.9% aberrations involving mixed lineage leukemia (MLL), 1.8% low hypodiploidy/near-triploidy, 1.2% Del (9p), 16.5% other chromosomal abnormalities, and 12.2% missing. Of 164 InO-treated patients, CR/CRi rate was 73% (95% confidence interval [CI] 66–80; **Table**) and MRD negativity rate was 59% (95% CI, 51–67). With InO, CR/CRi and MRD negativity rates were similar between the various cytogenetic subgroups. CR/CRi rates were significantly higher with InO *versus* SC in diploid (≥20 metaphases), complex, other, and missing cytogenetic subgroups (*P*≤0.015) and numerically higher in the other cytogenetic subgroups. With InO, more patients with diploid (≥20 metaphases) karyotype proceeded to stem cell transplant *versus* other cytogenetic subgroups. With InO, the duration of remission (DoR) was significantly different between cytogenetic subgroups (*P*<0.0001), with diploid (≥20 metaphases) and other subgroups having the longest median DoR numerically and MLL subgroup having the shortest median DoR numerically; no significant differences in DoR were seen between cytogenetic subgroups with SC (*P*=0.3783). Significant differences in PFS were seen between cytogenetic subgroups with InO (*P*=0.0063); no significant differences were seen between cytogenetic subgroups with SC (*P*=0.5427). Within the InO and SC arms, overall survival (OS) differences between cytogenetic subgroups were not significant (*P*=0.1629 and 0.3040, respectively); however, although not statistically significant based on 97.5% CI for hazard ratio (HR), OS was numerically longer (HR <1) with InO *versus* SC in diploid (≥20 metaphases), MLL, complex, other, and missing cytogenetic subgroups. Generally, adverse event profiles did not vary by cytogenetic subgroup.

Table 1.

	CR/CRi (95% CI)	PFS (95% CI)		OS (95% CI)	
	% Response	Median, mo	% 1 Year	Median, mo	% 1 Year
Dp with ≈20 metaphases (n=35)	83 (66–93)	6 (5–9)	25 (12–41)	9 (6–16)	36 (21–52)
Complex (n=28)	75 (55–89)	5 (3–6)	12 (3–28)	7 (4–12)	30 (14–47)
Ph+ (n=22)	73 (50–89)	4 (2–10)	26 (9–46)	9 (4–14)	41 (21–60)
Dp with <20 metaphases or unknown (n=11)	55 (23–83)	3 (1–5)	NA	5 (1–NA)	36 (11–63)
Hyperdiploid (n=8)	63 (25–92)	3 (1–9)	0 (NA)	6 (2–NA)	25 (4–56)
MLL (n=8)	63 (25–92)	2 (1–3)	0 (NA)	5 (2–13)	25 (4–56)
Ho-Tr (n=3)	67 (9–99)	4 (2–5)	0 (NA)	5 (2–6)	0 (NA)
Del (9p) (n=2)	100 (16–100)	NA	100 (100–100)	NA	100 (100–100)
Other abnormalities (n=27)	70 (50–86)	5 (3–9)	20 (7–38)	9 (5–NA)	41 (23–58)
Missing (n=20)	75 (51–91)	5 (2–6)	14 (3–34)	6 (4–10)	20 (6–39)
All (n=164)	73 (66–80)	5 (4–6)	17 (12–24)	8 (6–9)	34 (26–41)

CR/CRi=complete remission or complete remission with incomplete hematologic recovery; Dp=diploid; Ho-Tr=low hypodiploidy/near-triploidy; MLL=mixed lineage leukemia; NA=not available; Ph+=Philadelphia chromosome positive; PFS=progression-free survival; OS=overall survival.

Summary/Conclusions: In patients with diploid (≥20 metaphases), complex, other, and missing cytogenetic karyotypes, CR/CRi rates were significantly higher with InO *versus* SC. In the diploid (≥20 metaphases), MLL, complex, other, and missing cytogenetic subgroups, OS favored InO *versus* SC, though not statistically significant. Safety profiles generally were similar to the overall study population.

P520

A PHASE II STUDY WITH A SEQUENTIAL CLOFARABINE-CYCLOPHOSPHAMIDE COMBINATION SCHEDULE AS SALVAGE THERAPY FOR REFRACTORY AND RELAPSED ACUTE LYMPHOBLASTIC LEUKEMIA (R/R ALL) IN ADULT PATIENTS

G. Rotondo, [6]Policlinico S. Orsola - Malpighi, Bologna, [7]Universita' degli Studi di Bari Aldo Moro, Bari, [8]Spedali Civili, Brescia, [9]ASST Papa Giovanni XXIII, Bergamo, [10]Ospedali Riuniti Villa Sofia-Cervello, Palermo, [11]A.O. Bianchi-Melacrino-Morelli, Reggio Calabria, [12]Hematology, Ospedale dell'Angelo, Mestre Venezia, [13]GIMEMA Data Center, [14]Universita' degli Studi Sapienza, Roma, Italy

Background: Clofarabine (CLO) was demonstrated active in R/R ALL in combination with cyclophosphamide (CY) and/or other agents. An encouraging complete remission rate (CR 4/6, 67%) was obtained with a reference CLO-CY combination (Karp J et al, *Blood* 2007), however severe toxicity partly related to very high CY dosage forced stepwise reduction of CLO from 40 to 20-10mg/m^2/d.
Aims: A modified schedule combining full-dose CLO with attenuated CY (given after 2 hrs to inhibit CLO-damaged DNA repair) was piloted by GIMEMA. Here we report the activity and toxicity of the new CLO-CY regimen.
Methods: Study GIMEMA LAL1610 (EudraCT 2010-019742-12) had a two-stage Simon design, with an exploratory cohort of 10 patients and, provided a complete remissions (CR) was achieved in 3, an extension cohort of 17 patients. Primary study endpoint was CR rate, with 11 CRs (40%) required to declare CLO-CY worthy of further investigation. CRi was CR with incomplete recovery of neutrophils (<1.0) and/or platelets (<100). Eligible patients were adults with Philadelphia-negative (Ph-) R/R ALL, either primary refractory or in first isolated marrow relapse <24 months from first CR, including relapse after allogeneic stem cell transplant (SCT). CLO was administered IV at 40mg/m^2/d for 5 consecutive days, followed after 2 hrs by IV CY 400mg/m^2/d. Clinical and hematological response was assessed on day 28 or later, according to clinical course and patient condition. One/two courses were planned, followed by allogeneic SCT when possible.
Results: From October 2012 to December 2015, 35 patients were screened and 27 enrolled. Median patient age was 38.7 years (range 20.5-59.6), 15 were male, 4 with T- and 23 B-precursor ALL, 2 refractory and 25 relapsed (after a median of 5.9 months, range 1.9-23.4), 5/11 evaluable with high-risk cytogenetics [2 complex; 2 t(4;11), 1 MLL-rearranged]. Median white blood cells and marrow blast percentage were 5.67 (range 1-55) and 73 (range 8-100), respectively. All but one patient (treatment interruption due to traumatic fall) received CY-CLO as planned. Nine patients achieved CR and 7 CRi after course 1 (overall response 59.2%; 6/10 in study stage one), 2 had a partial response, 5 were refractory, 3 died early and one survived with pancytopenic marrow. In relapsed patients, only the length of prior remission affected the probability of CR, from 44.4% (n=8/18) to 100% (n=6/6) if ≤ or >12 months, respectively (P=0.02). In 10 evaluable patients, median post-induction MRD was 0.01% (<0.001% in 3). Six CR patients received a second course, which was curtailed in 2 due to toxicity, and 10 responders had an allogeneic SCT (62.2%). Concerning toxicity, 10 patients experienced grade ≥2 toxicity, but apart from expected myelosuppression/infections only 6 therapy-related grade >2 adverse events occurred: hepatic (n=4), renal (n=1) and neurological (n=1). After a median follow-up of 17.7 months (range 1.2-29.5), 5 patients are in continuous CR, 5 relapsed, and 6 died in CR (3 post-allograft; SCT-related mortality 30%). Median and 1-year overall and disease-free survival (OS, DFS) are 6.5 months and 28.6% (95% CI, 15.3-53.3%), and 4.5 months and 34.7% (95% CI, 17.3-69.7%), and apart from patient age (OS: HR 1.053, P=0.01) no other risk factor or length of prior CR affected DFS/OS probabilities.
Summary/Conclusions: Although the management of R/R Ph- ALL remains largely unsatisfactory, this regimen with full-dose CLO plus attenuated CY proved feasible and yielded an appreciable CR rate in adult patients suffering from isolated marrow relapse within 24 months from date of first CR.

BLINATUMOMAB USE IN PEDIATRIC AND ADOLESCENT PATIENTS WITH RELAPSED/REFRACTORY B-PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA FROM AN OPEN-LABEL, MULTICENTER, EXPANDED ACCESS STUDY

F. Locatelli[1,2,*], G. Zugmaier[3], A. Vora[4], C. Rossig[5], C. Peters[6], B. Brethon[7], M. O'Brien[8], L. Belton[9], R. Handgretinger[10]
[1]Bambino Gesù Children's Hospital, Rome, [2]Department of Pediatric Hematology-Oncology, University of Pavia, Pavia, Italy, [3]Global Development, Amgen Research (Munich) GmbH, Munich, Germany, [4]Department of Haematology, Sheffield Children's Hospital, Sheffield, United Kingdom, [5]Department of Paediatric Haematology and Oncology, University Children's Hospital Münster, Münster, Germany, [6]Department of Stem Cell Transplantation, St. Anna Children's Hospital, Vienna, Austria, [7]Department of Pediatric Hematology, Robert Debré Hospital, Paris, France, [8]Department of Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States, [9]LB Biostatistics, London, United Kingdom, [10]Department of General Paediatrics and Haematology/Oncology, Children's Hospital, University of Tübingen, Tübingen, Germany

Background: Blinatumomab, a bispecific T-cell engager antibody construct, has shown antileukemia activity and tolerability in patients with relapsed/refractory B-precursor acute lymphoblastic leukemia (ALL).
Aims: We further evaluated safety and efficacy of blinatumomab in pediatric and adolescent patients with relapsed/refractory B-precursor ALL enrolled in an expanded access study (NCT02187354).
Methods: Eligible patients (aged >28 days to <18 years) had ≥5% blasts and relapsed/refractory B-precursor ALL (refractory to prior treatments, second or later relapse, or relapse after allogeneic hematopoietic stem cell transplantation [alloHSCT]). Blinatumomab was dosed by continuous intravenous infusion (4 weeks on/2 weeks off) for up to five cycles (≥5 to <25% blasts: 15µg/m^2/day; ≥25% blasts: 5µg/m^2/day on days 1-7 in cycle 1, then 15 µg/m^2/day). The primary endpoint was incidence of treatment-emergent (TE) and treatment-related (TR) adverse events (AEs). Key efficacy endpoints were complete response and minimal residual disease (MRD, measured by polymerase chain reaction or flow cytometry) response within the first two cycles, relapse-free survival, overall survival, and incidence of alloHSCT.
Results: Among the first 40 treated patients (median age, 9 [range, 1–17] years), 24 (60%) had experienced ≥2 relapses, 20 (50%) had relapsed after alloHSCT, and 5 (13%) were primary refractory; 18 (45%) had ≥50% blasts and 21 (53%) had prior alloHSCT. Safety and key efficacy outcomes are shown in the table. Twenty-five patients (63%) achieved a complete response within the first two cycles, 19 of whom had an MRD response. Eight patients relapsed and 20 died after treatment. Regardless of causality, the most frequent TEAEs were pyrexia (78%), cytokine release syndrome (CRS; 23%), vomiting (23%), and anemia (20%). All nine CRS events were grade 1 or 2, and one tumor lysis syndrome was grade 3. Ten (25%) patients interrupted treatment and two (5%) discontinued due to TRAEs; 13 (33%) patients had grade ≥3 TRAEs, including two of three neurologic events (depressed level of consciousness and headache; both grade 3). Two patients experienced fatal AEs, both of which were considered unrelated to blinatumomab.

Table 1.

	All Patients N=40
All TEAEs, n (%)	39 (98)
Grade 3	15 (38)
Grade 4	12 (30)
Fatal	2 (5)
Complete response[a], n (%)	25 (63)
<50% blasts	15 (68)
≥50% blasts	10 (56)
t(17;19)	2 (100)
	Responders N=25
MRD response among responders[a] <10^{-4}, n (%)	19 (76)
<50% blasts	12 (80)
≥50% blasts	7 (70)
t(17;19)	2 (100)
alloHSCT after complete response, n (%)	10 (40)

aWithin the first two cycles

Summary/Conclusions: Blinatumomab showed antileukemia activity in pediatric and adolescent patients with high-risk relapsed/refractory B-precursor ALL including t(17;19) and AEs were consistent with those previously reported for relapsed/refractory ALL.

Lee Moffitt Cancer Center, Tampa, [2]Kite Pharma, Santa Monica, [3]University of Texas MD Anderson Cancer Center, Houston, [4]Washington University School of Medicine in St. Louis, Saint Louis, [5]University of Miami Health System, Sylvester Comprehensive Cancer Center, Miami, [6]Stanford University School of Medicine, Stanford, [7]Dana-Farber Cancer Institute, Boston, MA, Boston, [8]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, [9]Vanderbilt-Ingram Cancer Center,, Nashville, [10]City of Hope National Medical Center, Duarte, [11]Mayo Clinic, Rochester, [12]UCLA David Geffen School of Medicine, Los Angeles, [13]University of Rochester Medical Center, Rochester, United States

Background: The incidence of acute lymphoblastic leukemia (ALL) is increasing, with nearly 6600 new diagnoses expected in 2016, of which >40% will

affect adults aged >20 years (https://seer.cancer.gov). Adult patients (pts) with B cell ALL show high-risk disease biology, high rates of relapse, and poor survival (*J Clin Oncol* 2011;29:532; *Blood* 2012;119:34). Promising results have been observed with KTE-C19, an anti-CD19 chimeric antigen receptor (CAR) T cell therapy, in refractory, aggressive non-Hodgkin lymphoma (*Blood* 2016;128:LBA-6), and suggest an opportunity to improve outcomes in ALL. Here, we present updated results from the phase 1 portion of ZUMA-3, a multi-center study of KTE-C19 in pts with high tumor burden ALL.

Aims: The goal of this study is to assess safety and efficacy of KTE-C19 in adult pts with relapsed/refractory ALL who have high disease burden.

Methods: Eligible pts were ≥18 years of age with relapsed/refractory ALL (Ph+ pts eligible), ≥25% bone marrow lymphoblasts, adequate organ function, and Eastern Cooperative Oncology Group status 0-1. Pts received 1 or 2 × 10^6 CAR T cells/kg after conditioning with cyclophosphamide and fludarabine. The primary endpoint of phase 1 was incidence of dose-limiting toxicity (DLT). Secondary endpoints were efficacy outcomes of KTE-C19, including complete response (CR) rates and biomarker associations.

Results: As of Nov 1, 2016, 11 pts were enrolled, and 10 were treated with KTE-C19. One pt had a serious adverse event prior to dosing and was not treated. KTE-C19 was successfully manufactured in a centralized facility for all pts across a broad range of baseline absolute lymphocyte counts in 6 days, with a turnaround time of ~2 weeks. Pts were 60% men, with 1-4 prior lines of therapy and high disease burden (median, 81% bone marrow lymphoblasts). No pt (0/3) experienced a DLT at the 2 × 10^6dose, and phase 1 was then expanded to 6 pts at the 2 × 10^6dose. One pt experienced a grade 5 adverse event of multi-organ failure due to cytokine release syndrome (CRS), and subsequent pts (n=4) received 1 × 10^6 CAR T cells/kg. Across all pts, the most common grade ≥3 adverse events were cytopenias (80%), febrile neutropenia (50%), pyrexia (40%), and transaminitis (40%). Grade ≥3 CRS and neurologic events were reported in 20% and 40% of pts, respectively. Cerebral edema was not observed. All CRS events resolved (except the grade 5 event); neurologic events resolved in 5 of 6 pts (1 grade 3 neurologic event ongoing at cut-off). Anti-CD19 CAR T cells achieved peak expansion within two weeks of infusion. Of the 8 efficacy evaluable pts, 6 (75%) achieved remission (including CR and CR with either partial or incomplete hematopoietic recovery) by day 28 disease assessment or earlier. All remissions (100%) were minimal residual disease-negative. Of the 6 pts achieving minimal residual disease-negative CR, two eventually relapsed, one with CD19- disease and one with CD19+ disease. Safety and efficacy data were similar across KTE-C19 doses. Updated pt number, follow-up, and biomarker data will be presented.

Summary/Conclusions: No DLTs were observed with KTE-C19 in adult pts with high BM disease burden; one pt with high disease burden had grade 5 CRS after completion of the DLT cohort. Manufacturing was successful in all pts; most pts achieved a minimal residual disease-negative CR. These results demonstrate promising efficacy with a manageable safety profile. Based on these results, ZUMA-3 continues to enroll pts, adding measures to further enhance safety and with planned expansion to phase 2.

Background: Blinatumomab, a bispecific T-cell engager antibody construct, has shown improved overall survival *vs* standard of care (SOC) chemotherapy in patients with Philadelphia chromosome−negative relapsed/refractory B-precursor acute lymphoblastic leukemia (ALL) in a randomized phase 3 study (*N Engl J Med* 2017;376:836-847).

Aims: We compared the incidence of adverse events (AEs) observed with blinatumomab *vs* SOC after adjusting for varying treatment exposure times for a more comprehensive evaluation of safety and tolerability.

Methods: Adults (aged ≥18 years) with relapsed/refractory B-precursor ALL (refractory to primary induction therapy or salvage therapy, first relapse <1 year, second or later relapse, or relapse after allogeneic hematopoietic stem cell transplantation) were randomized to receive either blinatumomab or SOC (1 of 4 predefined regimens). Blinatumomab was dosed by continuous intravenous infusion (4 weeks on/2 weeks off) for up to five induction cycles (9 µg/day on days 1-7 of cycle 1 and 28 µg/day thereafter). Up to four maintenance cycles (4 weeks on/8 weeks off) were allowed for up to 12 months. Exposure-adjusted event rates were calculated as the number of events x 100/total exposure time (shown in the table).

Results: Median (range) number of cycles were 1 (1-4) for SOC and 2 (1-9) for blinatumomab. The highest exposure-adjusted event rates (per 100 patient-years) were for pyrexia (507 SOC *vs* 376 blinatumomab), anemia (987 *vs* 229), thrombocytopenia (750 *vs* 126), and neutropenia (351 *vs* 121), all of which were lower for blinatumomab than for SOC. Febrile neutropenia (365 vs 93) and infections (1216 *vs* 436) were also lower for blinatumomab than for SOC (p<0.0001). Exposure-adjusted event rates for neurologic events were 743 for SOC *vs* 472 for blinatumomab, with median time (range) to onset of 7 (1−43) days and 7 (1−190) days, respectively, and grade ≥3 cytokine release syndrome (CRS) rates were 0 for SOC *vs* 10 for blinatumomab. The most frequently reported AEs in both cycles 1 and 2 were pyrexia, nausea, and anemia in both arms; CRS events in the blinatumomab arm decreased between cycle 1 and cycle 2 (14% *vs* 2%). The majority of fatal AEs were related to infection in both arms.

Table 1.

	Standard of Care N=109		Blinatumomab N=267	
Total exposure, years	14.8		89	
	Number of Events	Exposure-Adjusted Event Rate[a]	Number of Events	Exposure-Adjusted Event Rate[a]
All AEs	2037	13764	4108	4616
Grade 3	456	3081	707	794
Grade 4	195	1318	197	221
Fatal	19	128	51	57
Neurologic events	110	743	420	472
CRS	0	0	56	63
All serious AEs	95	642	311	349

aPer 100 patient-years

Summary/Conclusions: In this study, blinatumomab showed an AE profile consistent with that previously reported for relapsed/refractory ALL, including similar rates of manageable CRS and neurologic events. Exposure-adjusted event rates were generally higher in SOC *vs* blinatumomab, including for cytopenias and infections.

FACTORS ASSOCIATED WITH STEM CELL TRANSPLANTATION OUTCOMES IN PATIENTS WITH RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH INOTUZUMAB OZOGAMICIN *VERSUS* CONVENTIONAL CHEMOTHERAPY

M. Stelljes[1,*], D. J. DeAngelo[2], P. Kebriaei[3], N. Gökbuget[4], H. M. Kantarjian[3], A. Advani[5], A. Merchant[6], T. Wang[7], F. Loberiza[8], B. Sleight[7], E. Vandendries[9], D. I. Marks[10]
[1]University of Münster, Münster, Germany, [2]Dana-Farber Cancer Institute, Boston, [3]MD Anderson Cancer Center, Houston, United States, [4]Goethe University, Frankfurt, Germany, [5]Cleveland Clinic, Cleveland, [6]University of Southern California, Los Angeles, [7]Pfizer Inc, Groton, [8]Pfizer Inc, New York, [9]Pfizer Inc, Cambridge, United States, [10]University Hospitals Bristol NHS Foundation Trust, Bristol, United Kingdom

Background: Inotuzumab ozogamicin (InO) therapy in relapsed/refractory acute lymphoblastic leukemia (R/R ALL) resulted in superior complete remission (CR)/CR with incomplete hematologic recovery (CRi) rates *versus* (v) conventional chemotherapy (C) in the Phase 3 INO-VATE trial (NCT01564784; Kantarjian *NEJM* 2016 [data as of October 2, 2014). More InO v C patients (pts) proceeded to hematopoietic stem cell transplantation (HSCT; 41% [45/109] v 11% [12/109]; *P*<0.001).
Aims: To assess factors associated with outcomes after allogeneic HSCT in patients with R/R ALL who were previously treated with InO.
Methods: Full details have been published. Informed consent was obtained from all patients. Multivariate analyses (MVA) using Cox regression modeling were conducted to determine predictors of non-relapse mortality (NRM) and overall survival (OS).
Results: As of March 8, 2016, 108/326 pts underwent allogeneic HSCT (InO n=77; C n=31). Baseline characteristics were generally similar, except baseline platelet values were lower in InO v C pts. More InO v C pts achieved minimal residual disease negativity during study therapy (MRD^{neg} [best status]; 71% v 26%; *P*<0.0001). Less InO v C pts received additional therapy before HSCT (14% v 55%, *P*<0.0001). NRM rates were higher in InO v C pts at 1 year (yr; 36% [95% CI 26–47] v 20% [8–36]) and 2 yrs (39% [27–51] v 31% [13–51]), but relapse rates were lower (1 yr, 23% [15–33] v 29% [13–48]; 2 yrs, 33% [22–44] v 46% [24–65]). No significant difference in post-HSCT survival was detected in InO v C pts; however, visual inspection of the curve suggested the survival probability varied before and after 15 months post-HSCT (1 yr, 44% [95% CI 33–55] v 65% [44–79]; 2 yr, 39% [28–50] v 34% [15–54]). Fatal veno-occlusive disease (VOD) was observed in 5 InO pts (all during the first 100 days from the date of HSCT) and no C pts. MVA showed that conditioning regimens without dual alkylators and thiotepa were associated (2-sided; *P*<0.05) with lower risk of NRM and post-HSCT survival, respectively.
Summary/Conclusions: Compared with C, InO permitted more pts with R/R ALL to proceed to HSCT in CR/CRi with MRD^{neg} (best status). Despite increased NRM and fatal VOD, long-term survival was attainable in InO pts. In pts previously treated with InO, interventions to reduce NRM and improve OS after HSCT include avoiding dual alkylator conditioning regimens, especially those containing thiotepa.

Acute myeloid leukemia - Biology 3

DESIGNING THE NEXT GENERATION CD33-TARGETING ADC: IMGN779, SELECTED FOR POTENCY, NOVEL MECHANISM AND PRECLINICAL TOLERABILITY, WITH HIGH ACTIVITY IN DISSEMINATED AML MODELS AND MULTI-DOSE REGIMENS

S. Adams[1,*], A. Wilhelm[1], L. Harvey[1], L. Flaherty[1], K. Watkins[1], S. Sikka[1], P. Shah[1], W. Li[1], Y. Kovtun[1], C. Sloss[1], K. Lai[1], M. Miller[1], G. Payne[1]
[1]ImmunoGen, Waltham, United States

Background: Antibody-drug conjugates (ADCs) targeting CD33 are promising therapeutics in AML, where challenges are achieving efficacy while maintaining tolerability. Here, we report the payload/ linker design and selection resulting in a high-Therapeutic Index (TI) ADC with favorable preclinical toxicity profile across multiple species and antitumor activity in disseminated AML models and in multi-dose regimens. IMGN779, the final ADC design, is comprised of an indolino-benzodiazepine mono-imine DNA-alkylating payload, DGN462, coupled by a cleavable *N*-succinimidyl 4-(2-pyridyldithio)-2-sulfobutanoate (s-SPDB) linker to a CD33-targeting antibody.
Aims: Select the best ADC out of multiple preclinical anti-CD33 ADC candidates, and assess its activity *in vitro* and *in vivo* in AML models.
Methods: Unconjugated payloads were evaluated *in vitro* for cytotoxicity on human AML cell lines. Payloads were compared, as CD33-targeting conjugates, *in vitro* for cytotoxicity on human AML cell lines and *in vivo* for tolerability in mice and TI against human AML xenografts. ADCs with cleavable and non-cleavable linkers were evaluated for cytotoxicity on MDR-positive and -negative AML cell lines, for tolerability in mice and TI in AML xenografts. IMGN779, the final ADC design, was evaluated *in vivo* for toxicity in rats and cynomologus monkeys. IMGN779's antitumor activity was evaluated in disseminated models and in fractionated- and multi-dose regimens in AML xenografts.
Results: First, we selected a high affinity antibody to CD33 with retained ADCC activity. Next, given concerns for long-term toxicity of DNA crosslinkers, we prepared DNA alkylating (single strand DNA damage) and DNA crosslinking (double strand DNA damage) versions of our novel IGN payload class. Both versions had comparable IC50s on human AML cell lines as free drugs (12-260 *vs*. 5-77 pM) and as CD33-targeting ADCs (0.7 *vs*. 0.5 pM). However, *in vivo*, the CD33-targeting DNA alkylating ADC had a 5-fold higher MTD (maximum tolerated dose) in mice and 5-fold larger TI in AML xenograft models (MTD 950 *vs*. 190 µg/kg, by payload; TI of 95 *vs*. 19). In addition, the DNA crosslinking version led to delayed systemic toxicity at MTD, not seen in the DNA alkylating version even at its 5-fold higher MTD. Thus we selected the DNA alkylating version for further development. To determine the optimal linker design, we created ADCs with three different linkers, one non-cleavable and two cleavable, and based on improved *in vitro* efficacy (IC50) and *in vivo* safety/efficacy (MTD, TI), the s-SPDB cleavable linker with the DNA alkylating payload was chosen as the lead clinical compound, and named IMGN779. In multiple species, IMGN779 had a consistent toxicity profile (mice, rats and monkeys), producing reversible cytopenias with no or minor changes in transaminases and without histologic evidence of hepatotoxicity. Importantly, IMGN779 was highly active at a single dose 10 µg/kg (payload) in an MV4-11 (FLT3-ITD+) disseminated AML xenograft model, producing a 90% increased life span, and was well-tolerated and highly active in repeat dosing regimens (10 or 30 µg/kg, qw x 3 and q3d x 3) in a HL60 AML xenograft model. Similarly, in a MV4-11 xenograft model, fractionated dosing (5 µg/kg, qw x 2 or q3d x 2) generated 33% more long-term tumor-free survivors compared to single-dose (10 µg/kg), demonstrating tolerability and enhanced efficacy in multi-dose and fractionated regimens.
Summary/Conclusions: IMGN779, designed as the next generation CD33-targeting ADC, utilizes a novel DNA alkylating DGN462 payload and a cleavable disulfide linker, selected to maximize anti-AML activity and preclinical safety. IMGN779 is highly active in multiple AML xenograft models, including models with poor prognostic factors, and is well-tolerated in preclinical repeat dosing regimens, where an additional benefit was achieved with a fractionating the dosing regimen over a single high dose. These results provide the foundation for the clinical evaluation of IMGN779 in AML.

THE MIXED LINEAGE LEUKEMIA FUSION PARTNER ENL RECRUITS PAF1 TO CLEAR POLYCOMB-INDUCED TRANSCRIPTIONAL REPRESSION

K. Hetzner[1], M. Garcia-Cuellar[1], C. Büttner[2], R. Slany[1,*]
[1]Biology, Institute of Genetics, [2]Biology, Institute of Hum.Genetics, Friedrich Alexander University Erlangen-Nürnberg, Erlangen, Germany

Background: In mixed lineage leukemia *ENL* is frequently found juxtaposed to *MLL* creating MLL-ENL fusion proteins that initiate leukemogenic transformation. Interestingly, mutations of *ENL* have also been found in Wilms' Tumor, a pediatric nephroblastoma. In its wild-type configuration ENL serves as scaffolding factor in protein complexes that stimulate transcriptional elongation but, paradoxically, it also co-purifies with polycomb repressive complex 1 (PRC1).

Aims: This work examines how ENL influences PRC1 repressive activity.
Methods: The effect of ENL on transcriptional activity of model promoters and endogenous transcriptional control elements was studied by biochemical and molecular biology methods.
Results: Here we demonstrate that ENL overcomes polycomb induced silencing through recruitment of polymerase associated factor 1 (PAF1) a chromatin reader linked to a histone ubiquitination complex. The ability to bind PAF1 controlled the ability of ENL to neutralize polycomb-mediated repression in an elongation reporter system and also during transformation of primary cells by MLL-ENL *in vivo*. Inactivation of polycomb by ENL was accompanied by ubiquitination of histone H2B, the hallmark activity of PAF1 allied enzymes. On a global level ChIP-Seq and nascent RNA-Seq demonstrated that MLL-ENL target genes stood out with a supraphysiological accumulation of H2BUb accompanied by hyper-accelerated transcription rates. Interestingly, examination of Wilms tumor specific ENL mutants allowed to elucidate the underlying mechanism of the MLL-fusion induced ENL hyperactivity. Introduction of Wilms-specific ENL mutants into primary hematopoietic cells induced aberrant transcription and H2BUb modification of *Hoxa9* and *Meis1,* two sentinel loci for polycomb action. This was dependent on the conserved YEATS domain of ENL that operated as "switch" binding either histone H3 or PAF1 thus effectively regulating ENL function as anti-repressor or elongation factor, respectively. Wilms-mutations aberrantly favored interaction with PAF1 and thus perturbed proper silencing. This effect was intensified in a MLL-ENL fusion where MLL itself provided a constitutive tether to PAF1 effectively creating a "super-transcription factor" that constitutively combined anti-repression with elongation capabilities.
Summary/Conclusions: In summary, targeting histone ubiquitination may be an additional Achilles heel for mixed lineage leukemia that merits further investigation of therapeutical utility.

P528

PKC EPSILON SUPPORTS ACUTE MYELOID LEUKEMIA BY MAINTAINING MITOCHONDRIAL REDOX HOMEOSTASIS

D. Di Marcantonio[1,*], E. Martinez[1], J. Vadaketh[1], S. Sidoli[2], E. Masselli[3], F. Ferraro[1], M. D. Milsom[4], C. Scholl[5], S. Fröhling[5], B. A. Garcia[2], P. Mirandola[3], G. Gobbi[3], T. Skorski[6], R. Garzon[7], M. Vitale[3], S. M. Sykes[1]
[1]Blood Cell Development and Function, Fox Chase Cancer Center, [2]Department of Biochemistry and Biophysics, University of Pennsylvania, Philadelphia, United States, [3]Department of Medicine and Surgery, University of Parma, Parma, Italy, [4]Experimental Hematology Group, Heidelberg Institute for Stem Cell Technology and Experimental Medicine (HI-STEM) and German Cancer Research Center (DKFZ), [5]Department of Translational Oncology, German Cancer Research Center (DKFZ), Heidelberg, Germany, [6]Department of Microbiology and Immunology, Fels Institute for Cancer Research and Molecular Biology, Temple University School of Medicine, Philadelphia, [7]Division of Hematology, The Ohio State University, Columbus, United States

Background: Although numerous genetic mutations contribute to the etiology and pathophysiology of acute myeloid leukemia (AML), the molecular machinery that is not mutated but supports AML biology remains largely unknown. Several studies have shown that AML cells, irrespective of genetic sub-type, display an oxidized intracellular redox environment compared to their healthy counterparts. The redox environment of AML cells is largely due to the elevated reactive oxygen species (ROS) levels, which are a class of free radical molecules. Though ROS are by-products of several cellular processes, in excess, they can damage DNA and destroy organelles, resulting in the acquisition of genetic mutations or cell death. As a result, ROS homeostasis is tightly regulated by an array of molecular pathways. Although ROS is elevated in AML cells, the role of ROS and the identity of its regulators remain largely unknown. Here we report that the serine/threonine kinase, PKCε regulates the ROS-neutralizing enzyme SOD2 to support mitochondrial redox homeostasis and AML progression.
Aims: The goal of this study was to identify and subsequently assess how targeting key ROS-regulatory pathways impacts AML biology.
Methods: Loss-of-function studies for PKCε and SOD2 were performed with recombinant lentiviruses expressing gene-targeting shRNAs. Recombinant retroviruses expressing either PKCε and SOD2/Catalase were used for gain-of-function assays. Cytoplasmic and mitochondrial superoxides and peroxides were measured using redox-sensitive GFP (roGFP) probes followed by flow cytometric analysis. Mitochondrial superoxides were also assessed by flow cytometric analysis of MitoSox stained cells. Proteomic analysis was achieved using nano LC-MS/MS. Annexin-V staining was analyzed by flow cytometry to measure cell death. *In vivo* and *in vitro* mouse studies were performed by FACS-based purification of shRNA-expressing cells followed either by: 1) growth in cytokine-enriched media or 2) transplantation into syngenic mice for survival analysis.
Results: We have discovered that inhibition of PKCε: 1) promoted the death of human and murine AML cell lines *in vitro*, 2) reduced AML progression driven by MLL-AF9 *in vivo* (p=0.0014) and 3) obstructed the growth of 5 out of 7 PD-AML samples *in vitro*. At the molecular level, we observed that PKCε inhibition led to a significant and dose-dependent increase in mitochondrial-produced superoxides–a specific type of ROS. Moreover, we found that enforced expression of PKCε can protect AML cells from lethal effects of superoxide-inducing agents 2-thenoyltrifluoroacteone and Antimycin A. To identify potential ROS-regulatory enzymes downstream of PKCε, we performed whole cell proteomics and found that the mitochondrial superoxide-neutralizing enzyme SOD2 is decreased in AML cells depleted of PKCε. Similar to PKCε inhibition, we also observed that genetic inhibition of SOD2 reduced the expansion of AML cell lines and PD-AMLs *in vitro* as well as significantly extended the onset of MLL-AF9-driven AML *in vivo* (p=0.0042). Finally, we also found that enforced expression of SOD2 in tandem with another anti-oxidant enzyme Catalase, reverses the anti-leukemia effects of PKCε inhibition confirming that PKCε supports AML pathophysiology by maintaining mitochondrial redox homeostasis.
Summary/Conclusions: Our results indicate that PKCε and SOD2 regulate mitochondrial redox homeostasis to support AML cell survival and disease progression and thus may represent a foundation for designing and developing novel therapeutic strategies.

P530

ROLE OF SHP2 IN A MOUSE MODEL OF AML CARRYING FLT3-ITD ALONG WITH LOSS OF TET2

R. Pandey[1,*], B. Ramdas[1], R. Chan[1], R. Kapur[1]
[1]Indiana University School of Medicine, Indianapolis, United States

Background: SHP2, a protein tyrosine phosphatase coded by Ptpn11, is an essential protein that integrates signals from several different tyrosine kinase receptors with all the major intracellular signaling pathways such as ERK, PI3K and STAT pathways and regulates cell survival, proliferation and differentiaition. One of the SHP2 dependent cytokine receptor kinase, FLT3 when mutated to be constitutively activated co-operates with other genetic lesions like loss of Tet2 and Dnmt3a leading to transformation of myeloproliferative neoplasm (MPN) to acute myeloid leukemia (AML) in mouse models. Tet2 and Dnmt3a are involved in regulation hematopoietic stem cell (HSC) self-renewal and differentiation programs through regulation of DNA methylation. One their own each of them leads to MPN but when present in combination, leads to AML. These mouse models of AML have a more pronounced stem cell phenotype and are resistant to traditional chemotherapy or FLT3 targeted kinase inhibitor.
Aims: Inhibition of SHP2 catalytic activity by a small molecule allosteric inhibitor has been recently demonstrated to retard the growth of receptor tyrosine kinase driven malignancies. Therefore, we wanted to investigate the role of SHP2 in leukemogenesis driven by loss of an epigenetic regualtor (Tet2) and aberrant cytokine receptor tyrosine kinase (Flt3-ITD) signaling.
Methods: Mice were intercrossed to generate $Ptpn11^{F/F}Tet2^{-/-}Flt3^{ITD/+}Mx1Cre^{+}$ or $Ptpn11^{F/F}Tet2^{-/-}Flt3^{ITD/+}Mx1Cre^{-}$ mice. Deletion of Ptpn11 was induced at 8-10 week of age by injecting poly IC and changes in the hematopoietic compartment were analyzed by flow cytometry. Cell autonomous and non-autonomous effects of Ptpn11 on leukemogenesis were also evaluated in transplantation models.
Results: After ploy IC induced deletion of Ptpn11 there was a significant difference in the median survival between leukemic mice with with deletion of Ptpn11 *versus* non-deleted (n=8). Though the Ptpn11 deleted leukemic mice showed almost complete loss of long term HSC with concomitant increase in short term proliferating HSC in the bone marrow, they were still able to home and engraft in lethally irradiated recipient mice. These results indicate that loss of Ptpn11 does not impair the engraftment of leukemic stem cells though in normal mice deletion of Ptpn11 impairs the ability to stem cells to home to bone marrow niche and engraft. Deletion of Ptpn11 in both primary mice and secondary recipients was also associated with deregulation of myeloid and lymphoid cell distribution both in the periphery and bone marrow. Mice with deletion of Ptpn11 in the context of $Flt3^{ITD/+}$did not generate immature or mature B cells. The effects of Ptpn11 deletion were more severe in primary mice as compared to mice that received Ptpn11 deleted cells or when Ptpn11 was deleted after transplantation suggesting a role for SHP2 function in the bone marrow microenvironment in this model of leukemogenesis.
Summary/Conclusions: SHP2 has been recognized as a proto-oncogene on the basis of its ability to induce hematological malignancies when it is constitutively active and loss of SHP2 catalytic activity is associated with inhibition of tyrosine kinase driven malignancies. Our results demonstrate that the role of SHP2 in AML is dependent upon the presence of other genetic mutations. SHP2 regulates AML with loss of Tet2 with concomitant expression of Flt3-ITD through influence on both leukemic cells and the bone marrow microenvironment.

P531

CLUSTER REGULATION OF RUNX FAMILY BY "GENE SWITCH" TRIGGERS A PROFOUND TUMOR REGRESSION OF DIVERSE ORIGINS

K. Morita[1,*], K. Suzuki[1], S. Maeda[1], A. Matsuo[1], Y. Mitsuda[1], A. Yano[1],

Y. Yamada[1], H. Kiyose[1], C. Tokushige[1], P. Liu[2], S. Adachi[1], H. Sugiyama[3], Y. Kamikubo[1]
[1]Department of Human Health Sciences, Graduate School of Medicine, Kyoto University, Kyoto, Japan, [2]Oncogenesis and Development Section, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, United States, [3]Department of Chemistry, Graduate School of Science, Kyoto University, Kyoto, Japan

Background: Although Runt-related transcription factor 1 (RUNX1) has been generally considered to be a tumor suppressor, a growing body of evidence suggests its pro-oncogenic property in acute myeloid leukemia (AML).
Aims: Demonstrate the anti-tumor potential of cluster regulation of RUNX with a "gene-switch" in AML as well as in dismal-prognostic solid tumors arising from diverse origins *in vivo.*
Methods: To assess the effect of RUNX-inhibition in AML cells, we performed series of shRNA-mediated RUNX knockdown experiments. To achieve cluster regulations of RUNX, we have computationally designed an agent which could irreversibly block the RUNX cluster genes expression profiling through dismantling protein-DNA interactions sequence-specifically (CRoX-1).
Results: Firstly, shRNA-mediated silencing of *RUNX1* stimulated cell cycle arrest at G_0/G_1 phase and induced apoptosis in AML cells bearing wild-type *p53*. Besides, RUNX1 depletion induced remarkable induction of p53 as well as its target gene products and additive knockdown of p53 in these cell lines reverted the phenotype of RUNX1-depletion, indicating that RUNX1 is functionally dependent on proficient p53 pathway. In addition, cycloheximide chase assay revealed that RUNX1 negatively regulates the protein stability of p53 in AML cells. In silico data analysis and ChIP-seq experiments together with series of knockdown and restore experiments identified BCL11A and TRIM24 as critical mediators of p53 pathway activation in *RUNX1*-inhibited AML cells.
Though *RUNX1*-depleted AML cells exhibited drastically slowed proliferation rate, a small sub-population of leukemia cells retained the proliferation potential even after the silencing of *RUNX1*. Analysis of these residual AML cells revealed the reciprocal up-regulation of *RUNX2* and *RUNX3* expressions, suggesting that *RUNX2* and *RUNX3* might compensate for the loss of *RUNX1* functions. As expected, additional knockdown of *RUNX2* and *RUNX3* in *RUNX*1-depleted AML cells effectively suppressed their proliferations. Thus the simultaneous targeting of all RUNX family members as a cluster provides more stringent control of leukemia cells. Finally, we examined the antitumor potency of CRoX-1-mediated cluster regulations of RUNX. CRoX-1 treatment was indeed highly effective against leukemia as well as dismal-prognostic solid tumors arising from diverse origins *in vitro*. Moreover, this reagent was exceptionally well-tolerated in mice and exerted excellent efficacy against xenograft mice models of AML, acute lymphoblastic leukemia, lung and gastric cancers, extending their overall survival periods *in vivo*. Since RUNX families take part in diverse physiologic functions not only in AML cells but also in normal hematopoietic cells and in various other vital organ tissues, we might expect criticisms in targeting whole RUNX family that it could trigger undesirable side-effects *in vivo*. Intriguingly, however, our drug was well-tolerated *in vivo* and through these experiments, we have coincidentally found that the amount of total RUNX expressions was consistently higher in malignant tissues compared to their normal counterpart ones, and we believe that this gap offers pharmacological window to be targeted in anti-tumor strategies. Furthermore, we found that higher expressions of estimated total RUNX amount demarcate significantly poorer-prognostic patient cohorts in a wide variety of cancers, underpinning the rationality of RUNX-inhibition strategies in cancer treatment.
Summary/Conclusions: This work identified the crucial role of RUNX cluster in the maintenance and the progression of cancer cells, and the indicated gene switch technology-dependent its modulation would be a novel strategy to control malignancies.

P532

PHOSPHOPROTEOMICS AND MASS CYTOMETRY SIGNATURES OF PRIMARY AML CELL DIFFERENTIATION ARE ASSOCIATED WITH SENSITIVITY TO KINASE INHIBITORS

P. Casado-Izquierdo[1,*], E. H. Wilkes[1], F. Miraki-Moud[1], M. M. Hadi[1], A. Rio-Machin[1], V. Rajeeve[1], R. Pike[2], I. Sameena[3], S. Marfa[1], N. Lea[4], G. Mufti[4], J. Gribben[1], J. Fitzgibbon[1], P. R. Cutillas[1]
[1]Centre for Haemato-Oncology, [2]Flow Cytometry Core Facility, [3]Tissue Bank, Barts Cancer Institute, [4]Haematological Medicine, King's College London School of Medicine, London, United Kingdom

Background: Kinase signalling is frequently deregulated in cancer cells. In the case of AML, the high recurrence of activating mutations in kinases and other kinase signalling regulators including FLT3 and RAS has stimulated the investigation of treatments based on kinase inhibitors. The success of kinase inhibitors depends of an accurate stratification of patients into response groups. The impact of genetic mutations on the sensitivity of primary AML to kinase inhibitors remains poorly defined and these have not been translated into effective therapies. The activity of a kinase can be affected by factors other than gene mutations and the sensitivity of leukemic cells to kinase inhibition depends not only on the activity of the targeted kinase. Thus, the integrative analysis of different biochemical features could improve the implementation of precision medicine therapies based on kinase inhibitors.
Aims: By the integration of multiple omics approaches, we aimed to generate molecular signatures, which can rationalize why some primary AML cells are resistant to treatment with different kinase inhibitors while others are sensitive to the same treatments.

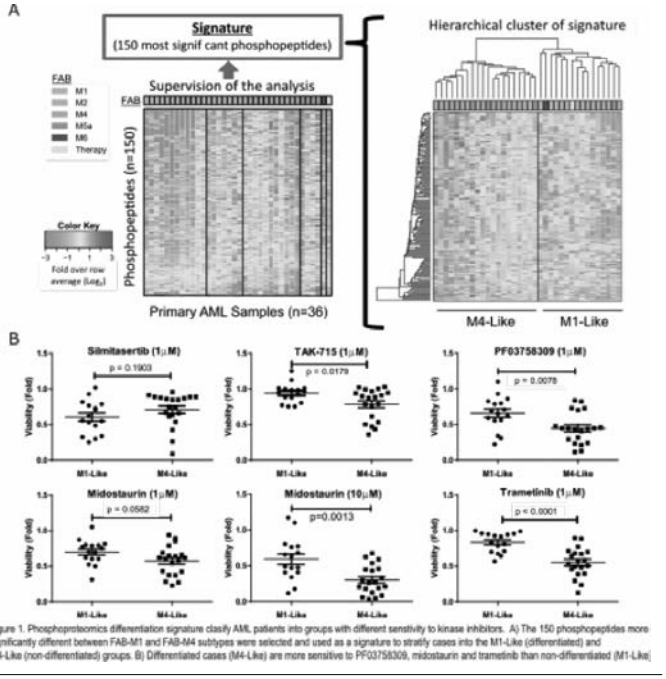

Figure 1. Phosphoproteomics differentiation signature classify AML patients into groups with different sensitivity to kinase inhibitors. A) The 150 phosphopeptides more significantly different between FAB-M1 and FAB-M4 subtypes were selected and used as a signature to stratify cases into the M1-Like (differentiated) and M4-Like (non-differentiated) groups. B) Differentiated cases (M4-Like) are more sensitive to PF03758309, midostaurin and trametinib than non-differentiated (M1-Like)

Figure 1.

Methods: In this investigation, we used a multiomics approach to stratify 36 AML biopsies as a function of their cellular sensitivity to "ex vivo" treatment with TAK-715, silmitasertib, PF03758309, midostaurin and trametinib, which target P38, CK2, PAK, FLT3/PKC and MEK, respectively. The same samples were analysed using different omics platforms: (i) mass spectrometry for phosphoproteomics, proteomics and kinomic profiling, (ii) mass cytometry for immunophenotyping and (iii) next generation sequencing for mutational profiling.
Results: Our integrative analysis identified two independent signatures that stratified our cohort of patients in sets of differentiated and undifferentiated cases. The phosphoproteomics signature divided our set of AML cases in the M1-like and M4-like groups (Figure 1A). The mass cytometry signature, which represented myelomonocytic markers that were co-expressed at the cell surface, split our cohort of patient in the CDs+ and CDs- groups. Remarkably, the M4-Like and CDs+ groups representing the differentiated cases, as well as the M1-Like and CDs- groups representing the non-differentiated cases, showed a high degree of overlap. Differentiated groups over-phosphorylated 3 times as many proteins as the non-differentiated groups, including kinases at sites linked to their activity. Mutations in genes involved in kinase signalling were also more frequent in differentiated cases. Kinase activity analysis using KSEA estimated that differentiated groups presented an enriched activity for PAK, MEK, ERK or PKC. Ontology analysis showed that non-differentiated cells over-phosphorylated nuclear proteins with DNA binding properties, while the differentiated cells increased the phosphorylation of membrane and cytoplasmic proteins linked to the small GTPase signalling. More interestingly, cases in differentiated groups were more sensitive to PF03758309, trametinib and midostaurin than those in the non-differentiated sets (Figure 1B for groups defined by the phosphoproteomics signature). Finally, differentiated cases as defined by the mass cytometry signature in our cohort of patients, or by a CD marker mRNA expression signature in the ATCG database, presented with significantly reduced survival when compared to the groups of non-differentiated cases.
Summary/Conclusions: Our data indicate that differentiated cells activate pro-survival kinases like PAK, PKCD or MEK which make them more sensitive to the inhibitors PF03758309, midostaurin or the FDA-approved drug trametinib. Since patients with differentiated cells present a reduced overall survival, treatment with these compounds may benefit patients in this higher risk group.

Background: Based on the prognostic significance, as well as the association with certain biological and clinical features, acute myeloid leukemia (AML) with biallelic mutations in the *CCAAT/enhancer-binding protein-alpha* (*CEBPA*^{bi}) gene has been included as a distinct entity into the 2016 revision to the World Health Organization classification of myeloid neoplasms and acute leukemia. *CEBPA* mutations (*CEBPA*^{mut}) are mainly found in AML with normal cytogenetics, and approximately 60% of the mutated patients (pts) carry biallelic mutations. Several studies showed that *CEBPA*^{bi} occur almost mutually exclusive with regard to other AML associated gene mutations such as *NPM1* or *FLT3*-ITD mutations. Recently, mutations in the *tet oncogene family member 2* (*TET2*^{mut}) gene were described as a frequent concurrent mutation of *CEBPA*^{bi}. Both genes are involved in the control of proliferation (*CEBPA*, *TET2*) and differentiation (*CEBPA*) of myeloid progenitors. Preliminary data suggest that pts harboring the *CEBPA*^{bi}/*TET2*^{mut} genotype have a significantly worse overall survival (OS).
Aims: To evaluate the frequency and the clinical impact of *TET2*^{mut} within a large cohort of *CEBPA*^{mut} AML pts.
Methods: In total 200 AML pts (age 18 to 78 years) with *CEBPA*^{bi} (n=113) or *CEBPA* single mutations (*CEBPA*^{sm}) (n=87) were analysed for the presence of *TET2*^{mut}. All pts were enrolled in one of 6 AMLSG treatment trials applying intensive therapy [AMLHD93 n=14; AMLHD98A (NCT00146120) n=53; AMLHD98B n=12; AMLSG 07-04 (NCT00151242) n=74; AMLSG 06-04 (NCT00151255) n=25 and AMLSG 12-09 (NCT01180322) n=22]. *TET2* mutation screening was performed using a DNA-based PCR-assay covering exons 3 to 9 followed by Sanger sequencing.
Results: In total we detected 52 *TET2*^{mut}in 39 of the 200 pts (19.5%); in 16 pts *TET2*^{mut} co-occurred with *CEBPA*^{bi} (16/113, 14.2%), 23 pts had concurrent *CEBPA*^{sm} (23/87, 26.4%). All *TET2*^{mut} were heterozygous, with 13 pts having two mutations. The median follow-up of the 200 pts was 76.3 months (95%>CI: 68.5–84.2). *TET2*^{mut} were restricted to the cytogenetic intermediate-risk group (100%), and pts with *TET2*^{mut} were significantly older than pts with *TET2* wild-type (*TET2*^{wt}) (64y *vs* 49y, *P* <.0001). In addition, *TET2*^{mut} were more frequent in secondary/therapy-related AML (*P* =.04), and there was a significant association with *SRSF2* gene mutations (*P* =.01). With regard to outcome, pts with *TET2*^{mut} had a significantly shorter event-free (EFS), relapse-free (RFS), and OS compared to *TET2*^{wt}pts (*P* <.0001, *P* <.0001 and *P* =.0001, respectively). Evaluating the impact of *TET2*^{mut} within the subgroup of *CEBPA*^{bi} pts (n=113), we found a significant association of *TET2*^{mut} with older age (49y *vs* 46y, *P* =.05), and an inferior EFS (*P* =.001), RFS (*P* =.0003), and OS (*P* =.007). Finally, we analysed the impact of *TET2*^{mut} within the subgroup of *CEBPA*^{sm} pts (n=87). Also, in this subgroup *TET2*^{mut} were found to be significantly associated with older age (66y *vs* 51y, *P* <.0001), and with *SRSF2* mutations (*P* =.02). Clinically, pts with *TET2*^{mut} had a shorter RFS (*P* =.02) and OS (*P* =.05), and in trend a shorter EFS (*P* =.09).
Summary/Conclusions: In our study on a large cohort of *CEBPA*^{mut}AML pts we could confirm the high incidence of concomitant *TET2* mutations (19.5%). Pts with concurrent *TET2*^{mut} were significantly older and had an inferior outcome.

P534

GFI1B–A NOVEL ONCOSUPPRESSOR WHICH RESTRICTS NUMBER OF LEUKEMIC STEM CELLS

A. Thivakaran[1,*], L. Botezatu[1], J. Hönes[1], Y. Al-Matary[1], J. Schütte[1], P.K. Patnana[1], R. Koester[1], B. Opalka[1], U. Dührsen[1], C. Khandanpour[1]
[1]Hematology, University Hospital of Essen, Essen, Germany

Background: Myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML) are hematopoetic disorders, which affect the myeloid lineages of hematopoiesis. Both are characterized by an accumulation of blast cells in the bone marrow (BM) that have the lost the ability to differentiate to mature cells. The proper differentiation of hematopoietic stem cells (HSCs) is regulated by transcription factors. Growth factor independence 1b (Gfi1b) is a repressing transcription factor regulating quiescence of HSCs and the proper emergence and maturation of erythrocytes and platelets.
Aims: Aim of the study was to identify I) do different level of Gfi1b influence onset and development of MDS and AML in human patients II) how does Gfi1b act in MDS/AML development on a molecular level.
Methods: We correlated Gfi1b expression level in blast cells of patients with MDS and AML with the overall disease course. To get a better insight how does different Gfi1b level influence MDS/AML development, we used three different murine models of human AML with expression of different oncogenes (NUP98/HOXD13, MLL-AF9 and expression of a mutated K-Ras). In these models we either downregulated or conditionally knocked out Gfi1b expression. Finally, we performed ChIP Seq analysis as well as whole genome gene expression arrays to study the molecular functions of Gfi1b in AML development.
Results: Low expression or absence of Gfi1b expression was associated with an inferior outcome with regard to overall-survival as well as event-free survival of MDS/AML patients. Using the above murine models of MDS/AML, loss or low expression of Gfi1b accelerated AML development. Additionally we could show that loss of Gfi1b significantly enhanced number of functional leukemic stem cells. It is well known that Gfi1b has a function to recruit histone modifying enzymes to induce among other deacetylation of H3K9. ChIP seq data of Gfi1b deficient leukemic cells revealed that loss of Gfi1b led to a higher H3K9 acetylation of a number of target genes, among them a number of oncogenes. Among these target genes, we found MAPK as well as Reactive oxygen species (ROS) signalling, as one of the top hit in our data. Previously it was reported that loss of Gfi1b enhanced the ROS level in HSCs. In our case we also see an increased expression of ROS in Gfi1b deficient leukemic cells, a higher activity of the FOXO pathway as well as reduced p38 activity. The combination of these foundings contributes to the higher number of leukemic stem cells in Gfi1b deficient leukemic cells. To reduce the high level of ROS in leukemic stem cells we use with N-Acetylcystein (NAC). Use of NAC impeded growth of Gfi1b deficient cells in-vitro.
Summary/Conclusions: Gfi1b act as a tumorsuppressor by restricting number of leukemic stem cells and treatment with NAC opens a potential targeted therapy for AML patients with low/absent expression of Gfi1b.

VARIANT ALLELE FREQUENCY KINETICS OF TYROSINE KINASE GENE MUTATIONS IN CORE-BINDING FACTOR ACUTE MYELOID LEUKEMIA (CBF-AML) UNDER TREATMENT WITH AND WITHOUT DASATINIB

M. Agrawal[1,*], N. Jahn[1], A. Dolnik[1], S. Cocciardi[1], L.K. Schmalbrock[1], T.J. Blätte[1], V. Gaidzik[1], M. Lübbert[2], W. Fiedler[3], T. Fischer[4], P. Brossart[5], M. Wattad[6], F. Thol[7], M. Heuser[7], A. Ganser[7], R.F. Schlenk[18], P. Paschka[1], H. Döhner[1], K. Döhner[1], L. Bullinger[1]
[1]Universitätsklinikum Ulm, Ulm, [2]Universitätsklinikum Freiburg, Freiburg, [3]Universitätsklinikum Hamburg-Eppendorf, Hamburg, [4]Universitätsklinikum Magdeburg, Magdeburg, [5]Universitätsklinikum Bonn, Bonn, [6]Evangelisches Krankenhaus Essen-Werden, Essen, [7]Medizinische Hochschule Hannover, Hannover, [8]Nationales Centrum für Tumorerkrankungen, Heidelberg, Germany

Background: Background: Recent next-generation sequencing (NGS) studies have improved our understanding of the genomic landscape of CBF-AML (Faber *et al. Nat Genet* 2016; Duployez *et al. Blood* 2016). While these studies have mainly focused on the genetic differences between inv(16)- and t(8;21)-AML at the time of diagnosis, the clonal architecture of relapsed disease is not well defined. Mutations affecting signaling genes, such as *KIT* and *NRAS* are known to be among the most common oncogenic drivers in CBF-AML, however their impact at relapse remains unclear.
Aims: To characterize clonal evolution in paired samples obtained at diagnosis, during remission and at relapse under treatment with dasatinib *vs* conventional chemotherapy, and ii) to conduct gene set enrichment analyses.
Methods: Whole-exome-sequencing (WES) was performed in paired diagnosis, remission and relapse samples of 36 patients with CBF-AML [inv(16), n=24; t(8;21), n=12] using paired-end sequencing (read length 100 bp) on an Illumina HiSeq platform. Library preparation was done with the Nextera® Rapid Capture Exome kit following manufacturer's instructions. All patients were treated within one of five trials of the German-Austrian Study Group (AMLSG). In two of the trials (AMLSG 11-08, NCT00850382; AMLSG 21-13, NCT02013648) patients received intensive chemotherapy in combination with the multi-kinase inhibitor dasatinib.
Results: The mean WES coverage was 133x. Mutations and indels were called with a threshold >10% variant allele frequency (VAF) after filtering for SNPs and sequencing artefacts. In sum, we identified 587 variants in 430 genes. At

diagnosis, 8.9 variants per patient were found as compared to 5.7 at relapse. 52% variants were present at diagnosis, 26% at relapse only, and 22% were present at both, diagnosis and relapse. With regard to the most commonly altered signaling genes *KIT* and *NRAS* we found the following pattern: The median VAF at diagnosis was 23% and 26% for *KIT* and *NRAS*, respectively. Of note, the initial *KIT* and *NRAS* clone was lost (VAF <5%) in 71% (exon 17, n= 9; exon 8, n=2; exon 11, n=1) and 100% of cases (exon 2, n=5; exon 3, n=3). Comparing the VAF kinetics between patients treated with and without dasatinib, baseline *KIT* mutations became subclonal (VAF <5%) in all patients receiving dasatinib (n=8), whereas they were still detectable in 4/6 (67%) patients who were intensively treated without the addition of dasatinib. *NRAS* became subclonal (n=8) irrespective of the treatment regimen. In one *KIT* mutated patient treated with dasatinib the baseline KIT^{D816V} mutation (exon 17) was lost at the time of relapse, but a KIT^{D419Y} mutation (exon 8) was acquired instead. Gene set enrichment analyses revealed different mutation signatures at diagnosis and relapse: At diagnosis, there was a significant enrichment for genes associated with MYC overexpression. Variants that were recurrently present at diagnosis and relapse showed enrichment for genes affected in KRAS overexpression models. Relapse samples were additionally enriched for gene mutations involved in the mitotic spindle assembly.

Summary/Conclusions: Differences in the allelic composition were found between diagnosis and relapse regardless of the CBF-AML subtype. Our data suggest that the *KIT* clone might be successfully eradicated under dasatinib treatment whereas persistence of *KIT* mutant clones was more commonly seen under conventional chemotherapy. The frequent loss of *KIT* and *NRAS* mutations during therapy suggests that relapse is triggered by alternative genetic lesions. Relapsed disease may represent a distinct biology which is characterized by mutations that cluster in different pathways. Further analyses are ongoing including study cohort expansion, as well as inclusion of RNA sequencing results.

Acute myeloid leukemia - Biology 4

P38B MAPK INTERACTS WITH SET REGULATING ITS INHIBITORY EFFECT ON PP2A ACTIVITY IN ACUTE MYELOID LEUKEMIA

E. Arriazu[1,*], C. Vicente[1], R. Pippa[1], N. Marcotegui[1], A. Igea[2], E. Leon[1], S. Chocarro[1], M. Soto[1], Á.R. Nebreda[2], M.D. Odero[1,3,4]
[1]Oncohematology, Center for applyed medical research University of Navarre, Pamplona, [2]Institute for Research in Biomedicine, Barcelona, [3]Instituto de Investigación Sanitaria de Navarra (IdiSNA),, Navarra, [4]Department of Biochemistry and Genetics, University of Navarra, Pamplona, Spain

Background: Despite improvements in our understanding of the molecular evolution of acute myeloid leukemia (AML), the overall cure rates remain low, and most patients die from the disease despite achieving initial remission upon treatment. It is therefore necessary to open new therapeutic perspectives aimed at molecular targets. PP2A phosphatase inactivation is a recurrent event in hematological tumors. Our group has reported that SET, an endogenous inhibitor of PP2A, is overexpressed in 28% of patients with AML. Furthermore, the anticancer activity of PP2A activating drugs (PADs) depends on the interaction/sequestration of SET, pointing out the significance of this oncogene in AML. Drug inhibition of several MAPKs in AML cell lines showed that only p38 inhibitors activate PP2A and decrease SET protein.

Aims: Therefore, we hypothesized that p38 could regulate SET at posttranslational level, leading to PP2A inactivation.

Methods: AML cell lines and primary human samples were analyzed by western blot, immunoprecipitation, immunofluorescence, treatment with pharmacological inhibitors and siRNAs. Phosphorylation assays by *in vitro* kinase assay with recombinant proteins were performed.

Results: Knockdown of the two major isoforms of p38-MAPK, p38α and p38β, demonstrated that only p38β was able to reduce SET protein levels and increase PP2A activity. To decipher this mechanism of action, we performed protein immunoprecipitation and immunofluorescence in the AML cell lines HL-60 and MOLM-13. p38β co-localized and bound to SET mostly in the cytoplasm stabilizing it, since treatment with ciclohexymide in the absence of p38β induced SET degradation. The stabilization role was in coordination with SETBP1, which co-localized with both SET and p38β. Interestingly, 12 out of 14 AML cell lines tested showed high expression of p38β protein levels but not of p38α, as well as 5 out of 7 AML primary patient samples. Furthermore, expression analysis in a large series of adult *de novo* AML cases previously reported (*Cancer Genome Atlas Research Network*, 2013) showed a positive correlation between *p38β* (*MAPK11*) and *SET* (R^2=0.416, p<0.001), but not between *p38α* and *SET.* We and others have shown that PADs retain SET in the nucleus. Our results showed that p38 phosphorylates SET not directly, but through the activation of casein kinase 2 (CK2), leading to the retention of SET in the nucleus and, therefore, contributing to the inactivation of PP2A in AML cells. Of note, CK2 is overexpressed in both AML cell lines and patient samples.

Summary/Conclusions: p38 is able to activate CK2 which phosphorylates SET and, as consequence, facilities its trafficking to the cytoplasm, contributing to PP2A inactivation in AML cells. Moreover, p38β binds to SET in the cytoplasm, contributing to its stability and leading to PP2A inactivation. In this regard, we have preliminary evidences that combination therapy with PADs and the CK2 inhibitor CX4945 reduces significantly the viability of AML cells, supporting that novel treatment modalities that can target multiple components of the same pathway may help to achieve a more sustained therapeutic benefit.

P537

GENETIC LANDSCAPE OF ACUTE ERYTHROID LEUKEMIA

Sanada[9], H. Tanaka[3], K. Usuki[10], S. Miyawaki[11], S. Miyano[3], A. Ganser[12], M. Heuser[12], S. Ogawa[1], F. Thol[12], K. Yoshida[1]
[1]Department of Pathology and Tumor Biology, Graduate School of Medicine, Kyoto Univrsity, Kyoto, Japan, [2]Division of Hematology-Oncology, Department of Internal Medicine, Chang Gung Memorial Hospital, Chang Gung University, Taoyuan, Taiwan, Republic of China, [3]Human Genome Center, Institute of Medical Science, The University of Tokyo, [4]Department of Pediatrics Graduate School of Medicine, The University of Tokyo,, Tokyo, Japan, [5]Department of Translational Hematology and Oncology Research, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH, United States, [6]Department of Hematology, NTT Medical Center, Tokyo, [7]Department of Hematology, Kanazawa University, Kanazawa, [8]Department of Hematology / Oncology, Graduate School of Medicine, Kyoto Univrsity, Tokyo, [9]Department of Advanced Diagnosis, Clinical Research Center,, National Hospital Organization Nagoya Medical Center, Nagoya, [10]Department of Hematology, NTT Medical Center, Kyoto, [11]Division of Hematology,, Tokyo Metropolitan Ohtsuka Hospital,, Tokyo, Japan, [12]Department of Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Background: Acute erythroid leukemia (AEL) is a unique subtype of acute myeloid leukemia (AML) characterized by the predominance of erythroid components with increased ring sideroblasts as well as frequent myelodysplasia. However, due to its rarity, the molecular pathogenesis of AEL has not fully been elucidated, except for frequent *TP53* mutations.
Aims: This study was designed to clarify the mutation profile of AEL distinct from other types of AML and myelodysplastic syndromes (MDS).
Methods: We performed a comprehensive genetic study, in which paired tumor/normal DNA from 22 AEL cases were analyzed using whole exome sequencing (WES). Whole-exome sequencing data from 3 AELs generated by The Cancer Genome Atlas (TCGA) was also included in the analysis. Subsequently, a total of 84 AEL cases were screened for mutations in 67 driver genes associated with myeloid malignancies using targeted-capture sequencing, in which RNA baits were also designed for a total of 1158 single nucleotide polymorphism sites to allow for genome wide copy number abnormalities and other allelic imbalances.
Results: Median age at diagnosis was 58.5 (21-87) years old. Among the 77 patients with clinical information available, 62 patients were diagnosed with *de novo* AML, 13 with secondary AML, and 2 with treatment-related AML. On average, 18.4 and 3.4 mutations were detected per sample in whole-exome and targeted-capture sequencing in AEL, as compared to 12.2 and 2.9 mutations (P<0.001 and 0.05) in other AML, respectively. Both platforms being combined, most frequently observed was *TP53* mutations (n=26, 31%) with complex karyotype being accompanied in most cases (25 cases), which were associated with a significantly shorter overall survival (P<0.001). Other frequently mutated genes were those encoding major components of the cohesin complex, including *STAG2* (24%), *SMC1A* (4.8%) and *RAD21* (2.4%), which were mutated in as high as 30% of the cases. The splicing machinery (18%) and epigenetic regulators (45%) were also common targets of mutations, including *SRSF2* (12%), *U2AF1* (4.8%), *WT1* (15%), *TET2* (19%) and *IDH1/2* (12%). *TP53* mutations were mutually exclusive with cohesin mutations (p<0.01) and those in epigenetic regulators (p=0.014). Compared to other types of AML cases reported from TCGA, AEL showed a significantly higher frequency of mutations in *TP53*, *STAG2*, *SRSF2*, *ASXL1*, *BCOR*, *WT1*, and *TET2*. These mutations have previously been shown to be enriched in secondary AML and MDS relative to *de novo* AML, which were also confirmed in our analysis involving 2,250 MDS cases. By contrast, *FLT3* (12%) and *DNMT3A* (12%) mutations and *SF3B1* mutations (0%) were significantly less frequent in AEL, compared to *de novo* AML and MDS. The frequency of these mutations was not statistically different between *de novo* AEL and secondary AEL.
Summary/Conclusions: WES and follow-up targeted-capture sequencing revealed a landscape of mutations in AEL. Frequent mutations in *TP53*, splicing factors, the cohesin complex, and epigenetic regulators were characteristic of AEL and thought to be involved in its pathophysiology. Mutations in *TP53* defined a subgroup with distinct genetic and prognostic features. Our result indicated a similarity between AEL and high-risk MDS/secondary AML, supporting the recent revision of the WHO classifications, in which AEL was reclassified into MDS and AML not otherwise unspecified.

P538

THE MOLECULAR LANDSCAPE OF MLL-PTD AML: SPECIFIC CONCURRENT MUTATIONS, CLINICAL OUTCOME AND GENE EXPRESSION SIGNATURES

A. Al Hinai[1,2,*], F. Kavelaars[1], T. Grob[1], M. Sanders[1], P. Valk[1]
[1]Hematology, Erasmus University Medical Center, Rotterdam, Netherlands, [2]National Genetic Centre, Muscat, Oman

Background: Partial tandem duplications (PTDs) in the Mixed Lineage Leukemia (*MLL*) gene, currently known as Lysine Methyltransferase 2A (*KMT2A*) are acquired in-frame internal duplications present in 5–11% of acute myeloid leukemia (AML). *MLL*-PTDs are predominantly present in cytogenetic normal AML and occasionally in AML with trisomy of chromosome 11. *MLL*-PTDs are generally considered as a poor prognostic marker in AML.
Aims: Evaluate the mutational landscape, prognostic value and gene expression signatures of *MLL*-PTD AMLs in comparison to a well-characterized AML cohort without *MLL*-PTD.
Methods: cDNA of 2310 AML patients enrolled in the adult HOVON-SAKK clinical trials (from 1995 to 2013) were analyzed for the presence of an *MLL*-PTD. Mutational screening based on next generation sequencing (NGS) was performed using the Illumina Trusight Myeloid panel on the Illumina HiSeq2500. An independent cohort of 632 *de novo* AML patients without *MLL*-PTD served as control. The gene expression profiling was assessed of all AML cases using Affymetrix HGU133 Plus2.0 GeneChips as previously described (Verhaak *et al.*, 2009).
Results: *MLL*-PTD was detected in 118 (5.1%) out of 2310 AML patients. *MLL*-PTDs were significantly associated with trisomy 11: 7% *vs* 1% (p=0.0037), normal karyotype: 65% *vs* 53% (p=0.0102) and complex karyotype: 1% *vs* 14% (p=0.0004). None of the *MLL*-PTD AML patients had any of the core binding leukemia fusion genes. The targeted NGS was performed on 87 out of 118 patients due to availability of gDNA. The number of mutation detected in *MLL*-PTD AMLs ranged from 0–6 mutations with an average of 3 mutations per patient. The most frequently mutated genes in *MLL*-PTD AMLs were *DNMT3A*, *FLT3*-ITD, *IDH2*, *RUNX1*, *IDH1*, and *TET2*. In the context of the 632 AMLs without *MLL*-PTD mutations in several genes appeared to be significantly associated with the *MLL*-PTD, i.e., *FLT3*-ITD: 34% *vs* 13% (p<0.0001), *IDH1*: 16% *vs* 9% (p=0.0133), *U2AF1*: 9% *vs* 3% (p=0.0158) and *IDH2*: 23% *vs* 12% (p=0.0181) or inversely associated, i.e., *NPM1*: 3% *vs* 32% (p<0.0001), *NRAS*: 5% *vs* 22% (p=0.0002) and *TP53*: 3% *vs* 10% (p=0.0487). Overall, the numbers of mutations in the spliceosome (p=0.03), tumor suppressor (p=0.0388), and transcription factor genes (p=0.0408) were significantly higher in *MLL*-PTD AMLs compared to *MLL* wild-type AMLs. As expected, the *MLL*-PTD appeared to be significantly associated with inferior outcome (*MLL*-PTD (n=74) and without *MLL*-PTD (n=1764); OS: p=0.05). Association of the presence of an *MLL*-PTD with EFS was only borderline significant (p=0.07). Within *MLL*-PTD AML, *DNMT3A* mutations are associated with inferior overall survival (HR: 2.06; 95%CI: 1.19-3.58; p=0.010). Although low numbers, *MLL*-PTD AML patients that harbor *NRAS* mutations do even worse (HR: 6.54; 95%CI: 2.45-17.49; p<0.001. In multivariate analysis both markers remain significant when combined with WBC counts and cytogenetics. Multiple homeobox-related gene family members were overexpressed in MLL-PTD AML. The top-35 differentially expressed genes included *HOXB5, HOXB6, HOXB7, HOXB8*, *HOXB9* and *NKX2.3.* In an association model, which takes all other known subsets of AML into account, other *HOX*-related genes, such as *HOXA7, HOXA9* and *NKX2.5*, also appeared significantly differentially expressed. In both analyses *MLL* itself seemed to be most consistently overexpressed in *MLL*-PTD AML. In contrast, these specific gene expression changes were absent in AML with translocations involving *MLL* on 11q23. Additional analyses in AML subsets based on the concurrent mutations will be carried out to investigate whether these are limited to certain *MLL*-PTD AML molecular subsets.
Summary/Conclusions: *MLL*-PTD AML carries specific gene expression signatures and specific subsets of concurrent mutations with clinical value.

P539

EXPLORING THE IMPACT OF LOSS OF FUNCTION STAG2 MUTATIONS ON CHROMATIN ARCHITETCURE IN MDS/AML

J. Smith[1,*], K. Savage[1], K. Mills[1]
[1]Centre for Cancer Research and Cell Biology, Queens University Belfast, Belfast, United Kingdom

Background: The Cohesin complex is an evolutionarily conserved multimeric protein complex consisting of SMC1, SMC3, RAD21, STAG1 & STAG2. The complex plays pivotal roles within mitosis and sister chromatid cohesion however, substantial data exists elucidating roles for the complex within the DNA damage response, homologous recombination and long-range interaction between *cis* regulatory elements of the genome. Within hematological malignancies upwards of 20% of patients diagnosed with either Acute Myeloid Leukemia (AML), Myelodysplastic syndrome (MDS) or Myeloproliferative neoplasm (MPN) have been shown to harbour mutations within the Cohesin complex, with many more showing significantly reduced expression of core complex members.
Aims: To explore the impact of a loss of function *STAG2* mutation on the chromatin architecture within a isogenic cell based model.
Methods: Using an CRISPR generated isogenic model we have investigated the impact loss of *STAG2* has on the chromatin architecture of a hematopoietic environment. Genome wide binding profiles for STAG1, STAG2 and CTCF were generated using ChIP-Seq to elucidate areas of differential between STAG members. In addition, binding profiles for H3K27ac, H3K27me3 and H3K4me1 were generated using ChIP-Seq to provide genome wide identification of active and repressed enhancer regions, with the regions ranked to identify both normal and super-enhancer regions. These samples were matched to ATAC-Seq profiling of open and closed chromatin regions as well as RNA-seq samples to provide information on gene activity in relation to chromatin state in the absence of STAG2.
Results: Our results indicate that STAG1 bindng profiles alter following loss of function of STAG2, with an increase in binding peaks from ~17,000 to 25,000, however several sites identified by ChIP-Seq are not compensated for. Histone mark profiling identified wide spread expansion of the H3K27ac mark and a decrease in regions of H3K27me3 consistent with loss of boundaries within topologically associated domains. This spread of an activator mark correlates with altered gene expression and the changes observed in ATAC-seq profiling of altered chromatin accessibility. The open chromatin regions identified through the use of ATAC-seq peak motif analysis yielded information regarding transcription factor occupancy. An enrichment for transcription factors relevant for myeloid transcriptional programmes was observed. This increase in enrichment aids in the suggestion that the impact of mutated/altered cohesin complex function relates directly to the specific cell type and maturation state at which it occurs.
Summary/Conclusions: This research into the aberrant and non-canonical nature of the cohesin complex provides evidence of the impact of mutant STAG2 on the spatio-temporal genomic architecture in hematological malignancies and begins to yield insight into the clinical implications of mutations within the cohesin complex.

P540

NEXT GENERATION SEQUENCING TECHNIQUES REVEAL MOLECULAR MECHANISMS OF MYB REGULATION AND FUNCTION IN MLL-AF9 LEUKEMIA

I.-J. Lau[1,*], A. Thomas[1], J. Kerry[1], L. Godfrey[1], C. Nerlov[1], P. Vyas[1], T. Milne[1]
[1]MRC Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Background: Mutations involving the *MLL* gene at 11q23 are found in 10% of adult and 18% of childhood acute myeloid leukaemia (AML) cases. The most frequently occurring *MLL* mutations are chromosome translocations that fuse the *MLL* gene in-frame with a second partner gene, creating novel fusion proteins (MLL-FPs). MLL-AF9 is the most common MLL-FP in AML. Despite much progress in the overall management of AML, patients carrying *MLL*-rearrangements still have a poor survival prognosis and limited response to existing therapy. This is in part due to the low therapeutic indices and narrow therapeutic windows of current chemotherapeutic agents, therefore underscoring the need to develop improved, targeted therapies. *MYB* is a direct downstream target of MLL-AF9. Recent studies indicate that MLL-AF9 leukemia cells are more affected by *MYB* knockdown compared to normal hematopoietic stem progenitor cells. This is despite the fact that *MYB* is known to be essential for the establishment of definitive hematopoiesis. This suggests that a therapeutic window may be achieved through targeting *MYB.* Therefore, by understanding more about the role of *MYB* in MLL-AF9 leukemia and the network it regulates, we maybe able to exploit this knowledge to target *MYB* directly by interfering with its function or indirectly via its downstream targets.
Aims: To understand the molecular function of *MYB* in MLL-AF9 leukaemia.
Methods: We performed genome-wide MYB, MLL-AF9, H3K27ac, H3K4me3 and H3K4me1 chromatin immunoprecipitation sequencing (ChIP-seq) and Assay for Transposase-Accessible Chromatin with high throughput sequencing (ATAC-seq) in two MLL-AF9 leukemia models to identify putative regulatory regions of *MYB* and those of a direct MYB gene target, *BCL2*. The chromatin conformation capture technique, Capture-C (one *vs* all) was used to further characterize interactions from the MYB promoter. We then performed siRNA knockdown of *MYB* and assessed the effect of MYB loss on its downstream druggable target *BCL2*, using RT qPCR, Western blotting and ChIP qPCR.
Results: We identified MLL-AF9 binding to novel putative enhancers of *MYB* as defined by regions co-bound by H3K27ac, H3K4me1 and marked by open chromatin on ATAC-seq. Furthermore, Capture-C from the MYB promoter identified novel putative enhancer-promoter interacting domains 100-200kb apart that are co-bound by MYB but not MLL-AF9. This suggests long-range autoregulation of MYB. Next, siRNA knockdown of MYB results in loss of MYB binding at the BCL2 promoter and its downstream enhancer by ChIP qPCR. There is a corresponding loss of *BCL2* mRNA and protein expression in MYB knocked-down cells compared with control, confirming that BCL2 is directly regulated by MYB.
Summary/Conclusions: We have identified for the first time, regulation of *MYB* by MLL-AF9 via putative enhancers, and also an autoregulatory role of MYB involving long-range cis-interactions. Furthermore, we confirm that *BCL2* is directly regulated by MYB in MLL-AF9 leukemia, suggesting a molecular rational for using BCL2 inhibitors in MLL-AF9 leukemia therapy.

P541

CD123-SPECIFIC CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPY IN ACUTE MYELOID LEUKAEMIA

S. Chitre[1,*], J. Gaken[1], A. Venuso[1], G. Mufti[1]
[1]Haematological Medicine, Kings College London, London, United Kingdom

Background: Acute myeloid leukaemia (AML) is a heterogeneous disease characterized by clonal evolution of myeloid precursors in bone marrow and peripheral blood resulting in accumulation of leukemic blasts and severe impairment of normal haematopoiesis. Despite advances in our understanding of AML biology, development of novel therapies has been limited with 43% relapse rate and 18% of patients never attaining clinical remission (CR) with frontline induction treatment. Chimeric antigen receptor (CARs) T cells specific for tumour-associated antigens are emerging to be an effective form of immunotherapy for AML. A small number of *in vitro* and *in vivo* studies have evaluated the efficacy and specificity of CAR T cell immunotherapy in AML by targeting interleukin three receptor alpha (IL3RA; CD123), a molecule over expressed on AML blasts and leukaemia stem cells (LSC) compared to normal haematopoietic stem cells (HSCs).
Aims: In this study, we investigated the efficacy of a second generation CAR expressing six single-chain variable fragments (scFv) with different affinities for CD123 and evaluated the cytotoxic effect of different co-stimulatory domains (CD28 *versus* 41BB) using a co-culture assay. Furthermore, we also evaluated the cytotoxic effects of a dual targeting CAR (against CD123 and CD33) using the same assay conditions.
Methods: Six lentiviral constructs (two high, two moderate & two low affinity) were transduced (MOI 1:5) into peripheral blood mononuclear cells (PBMCs) from healthy donors and their cytotoxicty was examined by flowcytometry on leukaemic cell lines; KG1 (CD123$^+$, CD34$^+$, CD33$^+$) [Fig:1a], Kasumi-1 (CD123$^+$, CD34$^+$, CD33$^+$), U937 (CD123$^+$, CD34$^-$, CD33$^+$), K562 (CD123$^-$, CD34$^-$, CD33$^+$) and AML mononucelar cells (MNCs).
Results: Flowcytometric analysis confirmed the expansion of T cells from PBMCs and the cytotoxicity of the six CARCD123 constructs against CD123^{+ve} cells. The high affinity CARCD123 (4nM kD & 4nM kD K136Q) T cells demonstrated enhanced cytotoxicity compared to moderate (56nM kD, 56nM kD A105G) and low affinity (101nM kD, 101nM kD V24G) CARCD123 in both leukaemic cell lines and also in allogenic AML MNCs. Both the highest affinity CARCD123 constructs were also tested in cell lines using increasing effector: target ratios (1:2, 1:4 & 1:10) displaying consistent cytotoxicity and were also effective against autologous AML MNCs (target cells) and PBMCs (effector cells) from two patients. T cell activation was confirmed by ELISA and showed increased IFN-γ (500-2000 fold) and TNF-α (150-200 fold) levels. Previous studies have confirmed the distinction in CAR efficiency using CD28 *versus* 41BB co-stimulatory domains; CD28 co-stimulation augmented, whereas 4-1BB co-stimulation reduced T cell exhaustion induced by continuous CAR signaling. To confirm persistence of the CAR cytoxicity, we constructed a high affinity CAR substituting CD28 with a 4-1BB co-stimulatory domain and obtained similar cytotoxicity results on K562 and U937 cell lines. Furthermore, a novel a dual targeting CAR in which the activation domain (CD3ζ) is directed against CD33 and the costimulatory domain (CD28) directed against CD123 enhanced the specificity of the CAR towards leukaemic cells; reducing "on-target but off-organ effects". Results obtained in co-culture assay against KG1 [Fig:1b] and K562 cell lines [Fig:1c] with varying effector: target ratios were demonstrated results similar to the high affinity single targeting CAR.

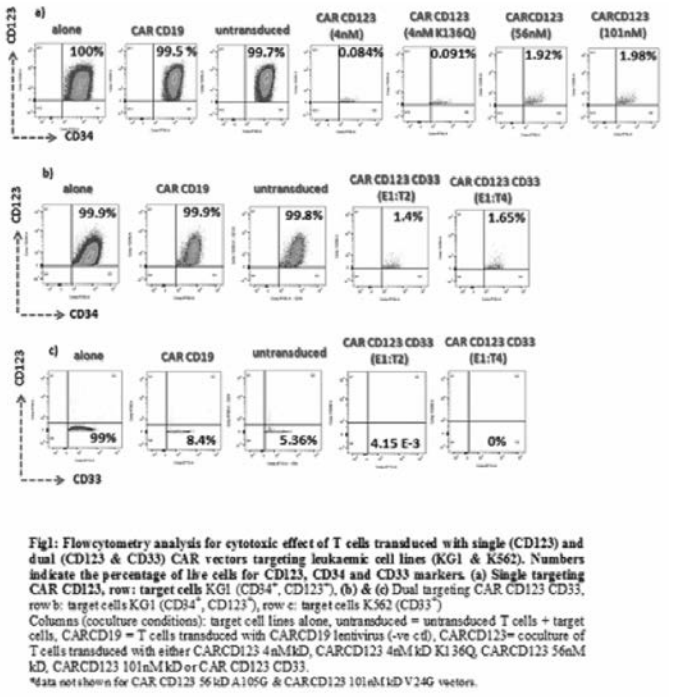

Fig1: Flowcytometry analysis for cytotoxic effect of T cells transduced with single (CD123) and dual (CD123 & CD33) CAR vectors targeting leukaemic cell lines (KG1 & K562). Numbers indicate the percentage of live cells for CD123, CD34 and CD33 markers. (a) Single targeting CAR CD123, row: target cells KG1 (CD34$^+$, CD123$^+$), **(b) & (c)** Dual targeting CAR CD123 CD33, row b: target cells KG1 (CD34$^+$, CD123$^+$), row c: target cells K562 (CD33$^+$)
Columns (coculture conditions): target cell lines alone, untransduced = untransduced T cells + target cells, CARCD19 = T cells transduced with CARCD19 lentivirus (-ve ctl), CARCD123= coculture of T cells transduced with either CARCD123 4nMkD, CARCD123 4nM kD K136Q, CARCD123 56nM kD, CARCD123 101nM kD or CAR CD123 CD33.
*data not shown for CAR CD123 56 kD A105G & CARCD123 101nM kD V24G vectors.

Figure 1.

Summary/Conclusions: In conclusion, we demonstrate the importance of the scFv on CAR T cell cytoxicity and have constructed and validated the efficacy of a dual targeting CAR vector in the context of AML.

P542

TARGETED COMBINATION THERAPY WITH CDK4/6 INHIBITOR PALBOCICLIB IN AML

I. Uras[1,*], P. Valent[2,3], V. Sexl[1]
[1]Institute of Pharmacology and Toxicology, University of Veterinary Medicine, Vienna, [2]Department of Internal Medicine I, Division of Hematology and Hemostaseology, [3]Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, Vienna, Austria

Background: Acute myeloid leukemia (AML) is a clonal hematologic disorder marked by clinical and biological heterogeneity. AML remains incurable for a significant proportion of adult patients while no therapeutic option exists for patients with relapsed and refractory AML. Mutations of the fms-like tyrosine kinase 3 (*FLT3*) gene are among the most frequent events in AML and usually involves internal tandem duplication (ITD) of the juxtamembrane domain coding region or point mutations of the tyrosine kinase domain. There have been considerable efforts to develop FLT3 tyrosine kinase inhibitors (TKI). The clinical impact of FLT3-TKI has been limited as resistant clones have emerged rapidly.

We have recently discovered that *FLT3*-ITD$^+$ AML cells are highly sensitive to the FDA-&EMA-approved CDK4/6 kinase inhibitor palbociclib (IBRANCE by Pfizer). The effect is ascribed to the transcriptional activity of CDK6 on *FLT3* and *PIM1*- a feature not shared by CDK4.
Aims: FLT3-TKI treatment provides short-term disease control but relapse invariably occurs within months. Acquired resistance on *FLT3*-D835Y tyrosine kinase domain is an emerging clinical problem. The focus of our study is to investigate the potential of palbociclib treatment in *FLT3*-D835Y$^+$ cells and to identify critical downstream effectors of CDK6 to open a novel, clinically applicable therapeutic window.
Methods: Ba/F3 cells transformed with *FLT3*-D835Y were exposed to single agents and drug combinations. Viability was measured by the CellTiter-Glo ATP-based assay and FACS stainings after 3 days of treatment. Validation was performed by *in vivo* xenograft models and by studies with primary human *FLT3*-D835Y$^+$ AML biopsies.
Results: Palbociclib impaired the viability of murine Ba/F3 cells with *FLT3*-D835Y at low concentrations. The effect extended to primary *FLT3*-D835Y$^+$ patient samples and to xenograft models, where palbociclib treatment effectively repressed *FLT3*-D835Y driven tumor formation *in vivo* at clinically relevant concentrations. Besides *FLT3* itself, which is regulated by CDK6, transcriptional targets of CDK6 in AML included Aurora kinases (AURK) and AKT. Thus CDK6 inhibition lead to decreased expression of AURK and AKT in mutant Ba/F3 cells, two signalling nodes critical for survival of tumor cells. Dual targeting with palbociclib and AURK or AKT inhibitors resulted in synergistic cytotoxicity.
Summary/Conclusions: Palbociclib represents a viable therapeutic option for use in treatment of resistant clones in *FLT3*-D835Y$^+$ AML. Inhibitory effects are caused by cell cycle inhibition as well as by transcriptional activity of CDK6 on important signalling pathways including Aurora kinases and AKT. Our findings provide the basis for the design of synergistic combination therapies with a CDK4/6 inhibitor which could be readily translated to patients with AML.

P543

CANNABINOIDS DERIVATIVES MODIFY THE PATTERN OF SPHINGOLIPIDS IN ACUTE MYELOID LEUKEMIA CELLS AND PRODUCE A POTENT ANTI-LEUKEMIC EFFECT

M. Medrano[1,*], M.V. Barbado[1], N. Campillo[2], F.J. Hidalgo[3], T. Caballero[1], I. Alvarez[1], O. Lopez[1], J.I. Piruat[1], J.A. Pérez-Simón[1]
[1]Instituto de Biomedicina de Sevilla, Seville, [2]CIB/CSIC, Madrid, [3]IG/CSIC, Seville, Spain

Background: Endocannabinoid system is a set of ligands, receptors and endogenous enzymes which modulate a variety of physiological effects. There are two well-characterized cannabinoid receptors, CB1 (mainly expressed in Central Nervous System) and CB2 (mainly in hematopoietic cells). Here, we tested the effect of the cannabinoid WIN-55 212-2 in acute myeloid leukemia (AML) *in vitro* and *in vivo* and studied the molecular signaling pathways involved in this effect, specially the role of sphingolipids. Moreover, we synthesized a new family of twelve cannabinoids that are specific to CB2 receptor.
Aims: - Development of new compounds derived from cannabinoids with CB2 selectivity and evaluation of their anti-tumor effect in AML *in vitro* and in vivo. To deepen in the knowledge of lipid metabolism in AML.
Methods: For the design and synthesis of new cannabinoids, computational techniques of docking, analytical and spectroscopic techniques such as mass spectrometry (MS) were used. To assess the anti-leukemia effect of the different cannabinoids, we analyzed cell viability by MTT and flow cytometry using six human AML cell lines, primary cells from healthy donors (hematopoietic progenitor cells (HPC) and lymphocytes) and blasts from AML patients. Mitochondrial damage was analyzed by flow cytometry using TMRE and by MitoSOXTM Red. In addition, we performed western blot and immunocytochemistry assays to determine the expression of different proteins to elucidate the molecular signaling pathways involved in the effect of these drugs.Moreover, we analyzed the ceramide levels, a membrane lipid associated with death/survival cell processes, and other sphingolipids by LC-MS/MS and immunohistochemistry. Finally, NOD/scid/IL-2R gammae null (NSG) mice were xenotransplanted with HL60 cell line. We confirmed disease infiltration in bone marrow (BM) by BM aspirates and flow cytometry assays. Once the presence of leukemic cells was confirmed, treatment with vehicle, WIN-55 cannabinoid at a dose of 5mg/kg/day or citarabine (ARA-C) at 50mg/kg during 5 days was administered. Also we tested the effect of these compounds on normal hematopoiesis by treating healthy BALB-C mice and the levels of sphingolipids in cell and plasma were studied in mice models.
Results: Cannabinoids induced a potent proapoptotic effect on AML cell lines and on primary leukemic cells, which was not observed in normal HPC and lymphocytes from healthy donors. Fragmentation of PARP and activation of caspases 2, 3, 8 and 9 were confirmed by Western Blot. The proapoptotic effect of cannabinoids on AML cells was abolished upon co-culture with either CB2 receptor antagonists or with pancaspase inhibitors. Other proteins involved in the effect of cannabinoids were p-AKT, p-ERK 1/2, p-38 and p- JNK. Also studies on p-PERK, p-IRE1 and CHOP confirmed an increased endoplasmic reticulum stress upon exposure to cannabinoids. Also we confirmed a very early mitochondrial damage in leukemic cells which was not observed in normal hematopoietic progenitor cells. Remarkably, we observed significant differences in the amounts of certain sphingolipids in untreated *versus* treated leukemic cells. More specifically in ceramide C16:0, C18:0 and C18:1. Also we observed a significantly increased survival among mice treated with WIN-55 cannabinoid as compared to both the control group and the group treated with ARA-C and we confirmed that cannabinoids did not affect the viability of the different populations of hematopoietic progenitors and, moreover, an increased platelet count was observed in treated mice.

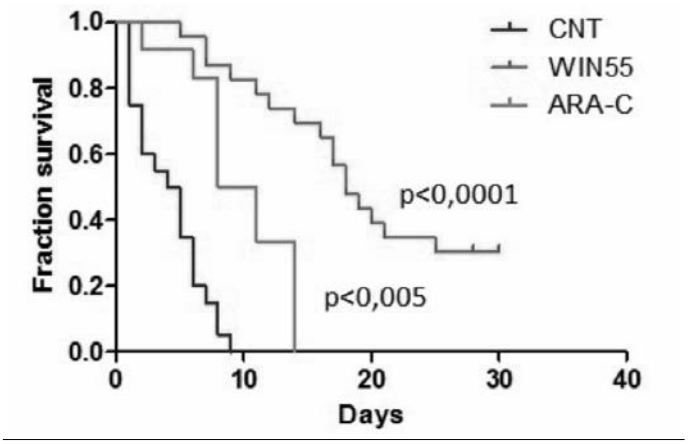

Figure 1.

Summary/Conclusions: Our findings indicate that cannabinoids display a highly selective proapoptotic effect against leukemic cells. Several pathways are involved in this effect, the modification in the sphingolipids pattern playing a main role.

P544

PROFILING THE MUTATIONAL LANDSCAPE OF ACUTE MYELOID LEUKEMIA AT RELAPSE AFTER CHEMOTHERAPY AND ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION.

E. Sala[1,2,*], F. Biavasco[1,2], G. Bucci[2,3], C. Toffalori[2], L. Zanotti[2], D. Biancolini[3], E. Antonini[4], M.G. Carrabba[1], B. Gentner[1,5], C. Tresoldi[4], M. Bernardi[1], D. Lazarevic[3], G. Tonon[3], F. Ciceri[1], L. Vago[1,2]
[1]Hematology and Bone Marrow Transplantation Unit; Division of Regenerative Medicine, Stem Cells and Gene Therapy, [2]Unit of Immunogenetics, Leukemia Genomic and Immunobiology; Division of Regenerative Medicine, Stem Cells and Gene Therapy, [3]Center for Translational Genomics and Bioinformatics, [4]Immunohematology and Transfusion Medicine Unit; Division of Regenerative Medicine, Stem Cells and Gene Therapy, [5]Translational stem cell and leukemia research Unit; SR-TIGET, Division of Regenerative Medicine, Stem Cells and Gene Therapy, San Raffaele Scientific Institute, Milano, Italy

Background: Acute Myeloid Leukemia (AML) is a clinically and biologically heterogeneous disease that is known to dynamically evolve over time. Unraveling its genetic profile may provide relevant insights into the inception, propagation, and recurrence of the disease, and deliver new rationales for precision medicine approaches: still, whereas a comprehensive description of AML mutations at disease presentation is now available thanks to large-scale studies, a satisfying genomic characterization of AML at relapse, particularly after allogeneic stem-cell transplantation (allo-HSCT), is still needed.
Aims: To characterize the genetic profile of relapsed AML, highlighting the evolutionary trajectories in the two different settings of relapse after chemotherapy (CT) and after allo-HSCT
Methods: For our custom-designed targeted Next Generation Sequencing panel we took advantage of the HaloPlex High Sensitivity (HS) technology, allowing a more precise definition of mutations and clonal architecture through a molecular barcoding system. We included in our panel 192 genes and miRNAs known to be involved in the pathogenesis of myeloid malignancies (n=112), in the DNA damage response (n=50), or in immune-related processes (n=30). Sequencing was performed on an Illumina HiSeq2500n instrument. Variant calling was performed using a pipeline based on the FreeBayes algorithm, and FLT3-ITD status was inferred using Pindel.
Results: We sequenced a total of 138 AML samples, including 79 diagnoses, 36 relapses after CT and 23 relapses after allo-HSCT. Sequencing yielded uniform and consistent coverage of all target amplicons and a 612x mean depth-of-sequencing, resulting on average in 117 unique barcodes for each region. Among the 79 diagnosis samples we identified 293 mutations (204 of which definable as oncogenic), with a median of 3 oncogenic mutations per patient (range 0-8), and mutation frequencies in line with the largest published dataset (Papaemmanuil, N Engl J Med, 2016; r^2=0.83). In relapses after CT and after allo-HSCT the median number of oncogenic mutations per patient was 3 (range 0-4) and 2 (range 0-6), respectively. Comparing mutation frequencies at relapse

with the Papaemmanuil dataset, we observed a weaker correlation for relapses after CT (r^2=0.69) and an even more marked deviation for post-transplant relapses (r^2=0.45). This difference was mainly explained by the enrichment in both relapse cohorts for FLT3-ITD (25% in diagnoses *vs* 55% and 48% at relapses after CT and allo-HSCT, p <0.01 for both comparisons) and WT1 mutations (5% *vs* 25% and 22%, p <0.01 for both comparisons). For 24 cases it was possible to longitudinally compare the mutational profile of AML at diagnosis and relapse in the same patient: we observed higher stability in relapses after CT, with 50% of cases carrying the same pattern of mutations present at diagnosis, whereas at relapses after allo-HSCT changes were more frequent, with 70% of patients displaying new gains or losses.

Summary/Conclusions: Taken together, our data evidence that the genomic landscape of AML at relapse can be significantly different from the one documented at diagnosis, suggesting that the selective pressure mediated not only by intensive chemotherapy, but also by the graft-versus-leukemia effect, can be potent drivers of clonal evolution. From the practical standpoint, the pattern of emergence of novel mutations that we documented should be taken into account not only for targeted salvage approaches, but also for the design of post-remission strategies aiming to prevent relapse.

AML PATIENTS AGED ≥75 YEARS ENROLLED INTO AMLCG TRIALS: DO GENETIC ALTERATIONS IMPACT CLINICAL OUTCOME IN VERY OLD, INTENSIVELY TREATED PATIENTS?

V. Prassek[1,*], M. Rothenberg-Thurley[1], M.C. Sauerland[2], S. Amler[2], D. Goerlich[2], T. Herold[3], H. Janke[1], S. Schneider[1], M. Subklewe[1], U. Krug[4], A. Faldum[2], W.E. Berdel[5], B. Woermann[6], J. Braess[7], W. Hiddemann[3], K. Spiekermann[3], K.H. Metzeler[3]

[1]Laboratory for Leukemia Diagnostics, Department of Internal Medicine III, University of Munich, Munich, [2]Institute of Biostatistics and Clinical Research, University of Muenster, Muenster, [3]Laboratory for Leukemia Diagnostics, Department of Internal Medicine III; German Cancer Consortium (DKTK), partner site Munich; German Cancer Research Center (DKFZ, Heidelberg), University of Munich, Munich, [4]Department of Internal Medicine III, Hospital Leverkusen, Leverkusen, [5]Department of Medicine A, Hematology and Oncology, University of Muenster, Muenster, [6]Department of Medicine, Hematology, Oncology, Tumor Immunology, Charité University Medicine Berlin, Berlin, [7]Department of Oncology and Hematology, Hospital Barmherzige Brüder, Regensburg, Germany

Background: Acute myeloid leukemia (AML) is a disease of the elderly (median age at diagnosis ~68 years). The prognosis of elderly patients (pts) is poor. Advanced age often leads to the judgement that pts are unfit for induction chemotherapy, although several trials have revealed a positive impact of intensive induction therapy in terms of sustained remissions and long-term survival in a subset of elderly pts.

Aims: We sought to validate existing risk classification systems and identify genetic factors associated with clinical outcomes in very old AML pts who received induction chemotherapy.

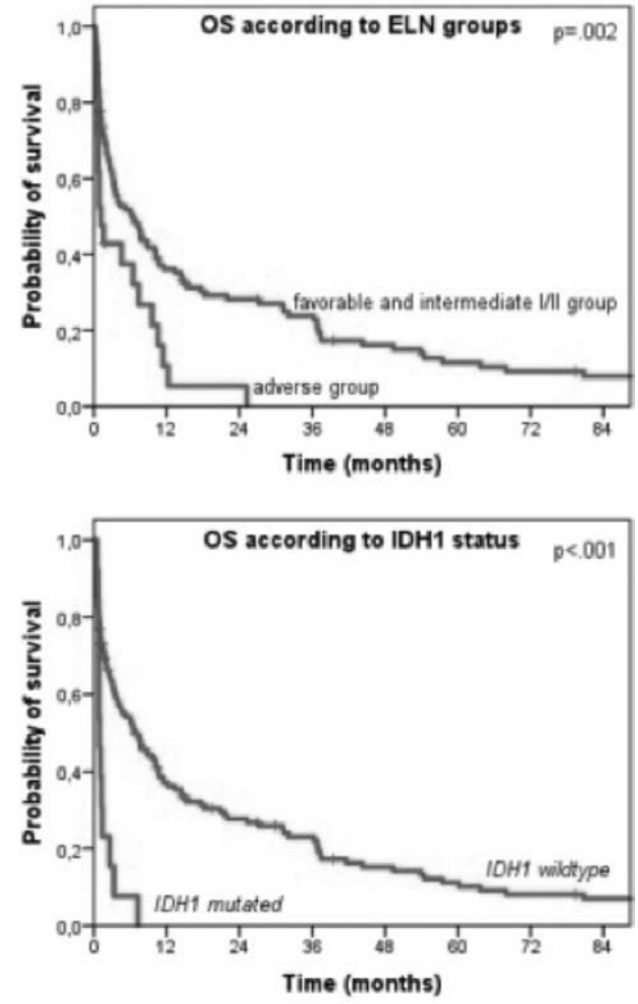

Figure 1.

Methods: We identified 151 AML pts aged ≥75 years who received intensive induction therapy in the AMLCG-1999 trial with suitable material for genetic

analyses. 81% of pts had *de novo* AML, 15% secondary AML, 3% therapy-related AML and 2% high-risk MDS. Recurrent gene mutations in AML were studied from bone marrow aspirates or peripheral blood using a targeted leukemia genotyping assay covering 68 genes. We analyzed known mutational hotspots or the entire coding sequence of the genes by multiplexed amplicon sequencing (Agilent Technologies, mean target coverage of 460 x). We studied associations between cytogenetics, gene mutations and other potential prognostic factors which might influence the clinical outcome.

Results: The median age in the total cohort was 76 years (y) (range: 75-86 y). 44% of pts reached complete remission (CR) and 4% CR with incomplete blood count recovery (CRi). The median overall survival (OS) was 6 months with a 3-year OS of 21%. According to the ELN 2010 classification, 20% of pts were in the favorable, 39% and 25% in the intermediate I or II group, respectively, and 15% in the adverse group (ELN 2017 data will be presented at the meeting). Pts in the favorable and intermediate I/II groups had significantly longer OS compared to the adverse group (median OS 6.3 *vs* 1.2 months, p=.002, Figure). Likewise, pts in the favorable and intermediate MRC cytogenetic risk categories had longer OS than those in the adverse category (median OS 6.5 *vs* 1.2 months, p=.001). By targeted sequencing, we detected 622 leukemia-associated mutations in 66 genes. The median number of mutated genes per patient was four. The most commonly mutated genes were *TET2* (42%), *DNMT3A* (35%), *NPM1* (32%), *SRSF2* (25%) and *ASXL1* (21%). Both *NPM1* or *EZH2* (5%) mutated pts showed a non-significant trend towards longer OS (*NPM1*: p=.09; *EZH2*: p=.065). *FLT3*-ITD mutations were identified in 29 pts (19%), but had no impact on OS (p=.297). The *NPM1*^{mutated}/*FLT3*-ITD^{negative} genotype also did not associate with OS. Notably, none of the 13 *IDH1* mutated pts (9%; all within the ELN favorable/intermediate groups) reached CR, and consequently the OS in this group was significantly shorter than for *IDH1* wild-type pts (p<.001; Figure). The positive impact of mutated *NPM1* on OS was reversed when it co-occurred with *IDH1* mutations (p=.014).

Summary/Conclusions: Among very old (≥75 y), intensively treated AML pts, adverse-risk cytogenetics predict inferior survival. On the other hand, 3-year OS was 24% for MRC/ELN favorable and intermediate-risk pts, suggesting that even in this age group, selected pts without medical contraindications benefit from intensive induction chemotherapy. The spectrum of driver gene mutations in elderly pts differs from that in younger pts. While *NPM1* and *FLT3*-ITD mutations had no significant impact on OS in intensively treated pts aged ≥75 y, our data imply *IDH1* mutations as a novel marker for chemorefractory disease and inferior prognosis in this age group.

P547

GMI-1271, A POTENT E-SELECTIN ANTAGONIST, IN COMBINATION WITH CHEMOTHERAPY IN RELAPSED/REFRACTORY AML: A NOVEL, WELL-TOLERATED REGIMEN WITH A HIGH REMISSION RATE

D.J. DeAngelo[1,*], B.A. Jonas[2], J.L. Liesveld[3], M.E. O'Dwyer[4], D.L. Bixby[5], A.S. Advani[6], P. Marlton[7], J.L. Magnani[8], H. Thackray[8], P.S. Becker[9]
[1]Dana-Farber Cancer Institute, Boston, [2]UC Davis Comprehensive Cancer Center, Sacramento, [3]Univ of Rochester James P Wilmut Cancer Ctr, Rochester, United States, [4]National University of Ireland, Galway, Ireland, [5]University of Michigan Comprehensive Cancer Center, Ann Arbor, [6]Cleveland Clinic Taussig Cancer Institute, Cleveland, United States, [7]Princess Alexandra Hospital, Brisbane, Australia, [8]GlycoMimetics, Inc., Rockville, [9]Fred Hutchinson Cancer Research Center, U of Washington, Seattle, United States

Background: Expression of the adhesion molecule E-selectin (E-sel) in the vasculature of the bone marrow is associated with infiltrative disease, relapse, and poor survival in AML. GMI-1271 is a novel antagonist of E-sel that down-regulates cell survival pathways and enhances chemotherapy response with improved survival compared to chemotherapy alone (Becker ASH 2013; Winkler ASH 2014). Protection from common toxicities (neutropenia and mucositis) has been observed in preclinical models, also affording survival benefit (Winkler ASH 2013).

Aims: We assessed GMI-1271 plus salvage chemotherapy with mitoxantrone, etoposide, and cytarabine (MEC) for the treatment of patients (pts) with relapsed/refractory (R/R) AML.

Methods: A Phase (Ph) 1 trial in pts with R/R AML escalated GMI-1271 across pharmacologically active doses from 5-20mg/kg combined with MEC to evaluate safety, tolerability and anti-leukemia activity. MEC consisted of mitoxantrone 10mg/m^2/d, etoposide 100mg/m^2/d, and cytarabine 1000mg/m^2/d IV for 5 days; supportive care was given as per institutional guidelines. Dose limiting toxicity (DLT) was defined as either persistent neutropenia and/or thrombocytopenia beyond day 42 in the absence of disease or any Grade 3 (Gr3) non-hematologic toxicity that did not resolve to Gr2 by day 42. After confirming safety and tolerability, a Ph 2 study of GMI-1271 at 10mg/kg plus MEC salvage chemotherapy was initiated; responders to salvage could receive consolidation with GMI-1271 plus reduced dose MEC (4 days). GMI-1271 was given 24 hrs prior, then every 12 hrs during and for 48 hrs post induction/consolidation. Eligible pts had an ECOG score 0-2, received ≤2 prior inductions, had WBC <20K (<40K after 2 dose levels), no active CNS disease, and adequate renal/hepatic function. Baseline E-sel ligand expression on leukemic blasts in the bone marrow (CD45/SSC by flow) was assessed, as were plasma levels of soluble E-sel (sE-sel).

Results: To date, 47 pts have enrolled (Ph 1=19; Ph 2=28 of planned 47). The recommended Ph 2 dose is 10mg/kg based on drug exposure, time over IC50 for E-sel binding, evidence of on-target effect (reduction in sE-sel), lack of DLT at any dose level, and clinical outcomes. Ph1/Ph2 combined median age was 55yrs (range 26-84) with 70% male pts. Prior AML history included 26% primary refractory, 36% CR1<6 mos; 17% prior SCT; 52% unfavorable cytogenetics (by SWOG). Common Gr 3/4 AEs were febrile neutropenia (36%), sepsis (26%), bacteremia (13%), hypoxia (13%). Oral mucositis (≥Gr 2) developed in 12% of pts. The 30 and 60 day mortality rates were 0 and 7%, respectively; induction mortality was 0%. The remission rate (CR/CRi) was 45% (19/42) with an ORR (CR/CRi/MLFS/PR) of 50% (21/42). Observed/expected remission (CR/CRi) ratio was >2.75 (Estey, Blood 1996). With a median follow-up of 11 mos, the Ph 1 median Disease Free Survival was not reached and Overall Survival was 7.6 mos. The median E-sel ligand expression at baseline was 35% (range, 1-75%) of blasts in the bone marrow, and was higher in those achieving remission.

Summary/Conclusions: The addition of GMI-1271, a novel E-sel antagonist, to MEC chemotherapy is well tolerated; oral mucositis, commonly severe with MEC, is observed at low severity in this study. Clinical outcomes include a high ORR and remission rate (CR/CRi), low induction mortality, and promising survival outcomes in pts with R/R AML. Furthermore, the baseline expression of E-sel ligand in this population suggests relevance of the target and is predictive of response.

P548

BST 236, A NOVEL CYTARABINE PRO-DRUG ALLOW, FOR THE FIRST TIME, THE DELIVERY OF HIGH CYTARABINE DOSES FOR OLDER OR UNFIT PATIENTS WITH ACUTE LEUKEMIA. RESULTS OF AN ONGOING PHASE I/IIA STUDY

T. Zuckerman[1,2,*], S. Gengrinovitch[3], R. Ram[4], L. Flaishon[3], R. Ben Yakar[3], R. Hoffman[1,2], I. Henig[2], N. Lavi[1,2], L. Akria[5], Y. Ofran[1,2], N.A. Horowitz[1,2], O. Nudelman[2], M. Koren-Michowitz[6], S. Yeganeh[7], J.M. Rowe[1,2,8]
[1]Bruce Rappaport Faculty of Medicine, Technion, [2]Hematology, Rambam Health Care Campus, Haifa, [3]Clinical, BioSight Ltd, Karmiel, [4]Hematology, Sourasky Medical Center, Tel-Aviv, [5]Hematology, Galil Medical Center, Nahariya, [6]Hematology, Assaf Harofeh Medical Center, Zerifin, [7]Hematology, Poria Medical Center, Tiberias, [8]Hematology, Shaare Zedek Medical Center, Jerusalem, Israel

Background: Acute myeloid leukemia (AML) is associated with poor outcome in older patients and in patients unfit for standard induction therapy. Therapy of AML has not changed significantly since the 1970s and still relies on cytarabine as the first-line treatment. However, cytarabine therapy is associated with severe side effects, such as cerebellar toxicity, bone marrow suppression, and infections, leading to high treatment-related mortality rates. Hence, while the incidence of AML increases with age, advanced age and comorbidities may preclude the administration of intensive therapy altogether.

Aims: BST-236 (Astarabine) is a new compound of cytarabine covalently bound to asparagine. It acts as a pro-drug of cytarabine, enabling delivery of high cytarabine doses to target cells with lower systemic exposure to the free drug and relative sparing of normal tissues. As such, BST-236 may serve as an ideal therapy for leukemia, particularly for delivering high doses of cytarabine to medically unfit or older adults. The aim of this study was to evaluate the safety and optimal dose of BST-236 in refractory/relapsed or newly-diagnosed AML patients unfit for standard induction therapy.

Methods: A Phase I/IIa prospective open label study enrolled adult relapsed/refractory or newly-diagnosed acute leukemia patients unfit for standard therapy. Patients are enrolled into 6 BST-236 escalating-dose cohorts (0.3-6 g/m^2/d), each composed of 3-6 patients. Treatment was administered as 1-hour daily infusion for 6 days.

Results: To date, treatment of cohorts 1-5 is completed, with 18 patients treated with up to 4.5 g/m^2/day, median age 77 (27-90): 6 relapsed/refractory AML patients, median age 64 (27-81), and 12 newly-diagnosed patients, unfit for standard chemotherapy (7 secondary AML; 5 *de novo* AML/ALL), median age 79 (70-90). BST-236 treatment was well-tolerated. Only 6 SAEs in 4 cases were assessed by the treating physician as possibly/probably related to BST-236, all "on-target" hematological toxicity events or bacterial infections derived from it. No neurological or grade >2 typical cytarabine events such as gastrointestinal, mucositis, or alopecia were reported during BST-236 treatment or within 30 days of follow up. Response to the treatment was observed in 6 of the 12 newly-diagnosed patients, 4 of whom had a continuous complete remission (CR) and 2 had a partial remission (PR). The median overall survival (OS) of the responding (CR+PR) and of the CR patients was 7 and 10 months, respectively. The median OS of the newly-diagnosed non-responders was 2.5 months. No remission was reached in the 6 patients suffering from relapse or refractory AML and their median OS was 2.3 months.

Summary/Conclusions: BST-236 is safe and very well tolerated, enabling delivery of high dose cytarabine to older and unfit patients, resulting in overall response and CR rates of 50% and 33%, respectively, and a 3-fold increase in median OS of the responding compared to the non-responding newly-diagnosed patients. Notably, 67% of the responding patients had secondary AML,

refractory to hypomethylating agents. To the best of our knowledge, this is the only experimental drug permitting high-dose cytarabine, considered a cornerstone of leukemia therapy, to be given to a population of patients that currently do not have this option. A phase II study is planned to confirm these encouraging results.

P549

FEASIBILITY AND BENEFIT OF TARGETED RNA SEQUENCING FOR THE DETECTION OF RECURRENT FUSION TRANSCRIPTS AND THE IDENTIFICATION OF NOVEL FUSION TRANSCRIPTS IN MYELOID MALIGNANCIES

C. Haferlach[1,*], N. Nadarajah[1], M. Meggendorfer[1], A. Stengel[1], W. Kern[1], T. Haferlach[1]
[1]MLL Munich Leukemia Laboratory, Munich, Germany

Background: Gene fusions are frequent genetic abnormalities in myeloid malignancies. The impact of the detection of such gene fusions is rising due to an increasing number of drugs targeting them as has been impressively shown for *e.g. BCR-ABL1* and *PML-RARA*. Further, they can be used as biomarkers for disease monitoring.
Aims: Evaluation of targeted RNA sequencing for the detection of recurrent and novel fusion transcripts.
Methods: 102 cases with myeloid malignancies harboring 105 translocations identified by chromosome banding analysis were selected. Recurrent fusion genes had been confirmed by FISH and/or RT-PCR. In cases with suspected novel fusions the rearrangement of one partner gene had been confirmed by FISH. The following recurrent rearrangements identified by standard diagnostic procedures were present: *PML-RARA* (n=11), *RUNX1-RUNX1T1* (n=7), *CBFB-MYH11* (n=3), *KMT2A-ELL* (n=4), *KMT2A-MLLT1* (n=4), *KMT2A-MLLT10* (n=3), *KMT2A-MLLT3* (n=3), *KMT2A-MLLT4* (n=2), *BCR-ABL1* (n=3), *NUP98-NSD1* (n=3), *DEK-NUP214* (n=1), and *KAT6A-CREBBP* (n=1). Further, cases harboring rearrangements involving *KMT2A* (n=14), *RUNX1* (n=21), *ETV6* (n=10), *PDGFRB* (n=10), *RARA* (n=2), *NPM*1 (n=2) and *NUP98* (n=1) were included. Targeted RNA sequencing was performed using the TruSight RNA Fusion panel (Illumina, San Diego, CA) consisting of 7690 probes covering 507 genes known to be involved in gene fusions. Library was prepared according to manufacturer's protocol with ~50ng RNA extracted from fresh/frozen samples. Sequencing was performed on the NextSeq instrument (Illumina) and analysis with the RNA-Seq Alignment App (BaseSpace Sequence Hub) using Star for Alignment and Manta for gene fusion calling with default parameters (Illumina).
Results: In 42/45 (93%) cases with a recurrent rearrangement identified by standard diagnostics, RNA sequencing detected the respective fusion transcript. In addition, RNA sequencing was able to identify known and novel fusions in the remaining 57 cases. For *KMT2A* these were the following partner genes: *MLLT1* (n=5), *ELL* (n=3), *ITPR2*, *FLNC*, *ASXL2, DCP1B, MAML1* and *ARHGEF12*. Seven different partner genes were identified in *RUNX1* translocated cases: *PLAG1* (n=2), *PRDM16*, *MECOM*, *ZFPM2*, *MAN1A2*, *N6AMT2*, and *KIAA1549L*. Five different partner genes were identified in *ETV6* rearranged cases: *ABL1*, *CCDC126*, *ERG*, *FOXO1* and *CFLAR-AS1*. Most strikingly was the identification of the *ETV6-ABL1* fusion, which could not be suspected by cytogenetics as the 5' *ETV6* FISH signal was located on chromosome 17. In 7/10 *PDGFRB* rearranged cases the partner genes were identified. These were *WDR48, CCDC88C, MPRIP, TNIP1, TPR, NFIA* and *ZBTB11*. Further the following fusions were found: *NPM1-RPP30, NPM1-SETBP1, NUP98-ING3, IRF2BP1-RARA,* and *ZBTB16-RARA*. Thus, RNA sequencing identified 39 fusions in 57 (68%) cases in which standard diagnostics had identified only one of the partner genes. Failure to detect gene fusions should initiate improvements in calling algorithms and may also have biological reasons. It was reported that genomic rearrangements of *RUNX1* occur, which do not lead to *RUNX1* in frame fusion transcripts but to termination of transcription.
Summary/Conclusions: 1) RNA sequencing was able to detect recurrent gene fusions with high accuracy and to characterize rare gene fusions providing the basis for the design of RT-PCR based assays for monitoring MRD. 2) Targeted RNA sequencing may be a valuable tool in routine diagnostics for patients with rearrangements unresolved by standard techniques. 3) These findings may have consequences for targeted treatment approaches.

COMPREHENSIVE MOLECULAR ANALYSIS OF ADULT MIXED PHENOTYPE ACUTE LEUKEMIA (MPAL)

K. Morita[1,2,*], F. Wang[3], K. Patel[4], C. Bueso-Ramos[3], A. Abou Zahr[3], C. Gumbs[3], L. Little[3], S. Tippen[3], R. Thornton[3], M. Coyle[3], J. Zhang[3], X. Song[3], M. Mendoza[3], C.-J. Wu[3], S. Kornblau[1], C. DiNardo[1], F. Ravandi[3], G. Garcia-Manero[1], E. Jabbour[1], M. Andreeff[1], H. Kantarjian[1], J. Cortes[1], M. Konopleva[1], A. Futreal[3], K. Takahashi[1]
[1]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Texas, United States, [2]Department of Hematology and Oncology, The University of Tokyo, Tokyo, Japan, [3]The University of Texas MD Anderson Cancer Center, Texas, United States, [4]Department of Hematopathology, The University of Texas MD Anderson Cancer Center, Texas, United States

Background: Mixed phenotype acute leukemia (MPAL) is a rare subgroup of acute leukemia characterized by blasts that show immunophenotypes of both myeloid and lymphoid lineages and therefore not traceable to single lineage of origin. Diagnosis of MPAL is challenging due to the possible discrepancy between immunophenotype and morphology. Clinically, MPAL has poor prognosis and poses therapeutic challenges. Genetic basis of MPAL is not well understood.
Aims: To clarify the underlying pathogenesis of MPAL and provide clue on future personalized therapy in MPAL, we performed comprehensive molecular characterization of adult MPAL.
Methods: We studied 31 patients with adult MPAL (median age 53) that met 2008 WHO classification criteria. Pre-treatment bone marrow samples were studied by targeted capture exome sequencing of 295 genes that are recurrently mutated in hematologic malignancies (median 393x coverage, N=31), RNA sequencing (N=24), and Infinium methylation EPIC array (Illumina, N=31). Mutational landscape was compared to that of 194 AML, 71 B-ALL, and 6 T-ALL cases of which pre-treatment samples were sequenced internally with the same platform. Promoter CpG methylation pattern was compared to the data from 194 AML (data derived from The Cancer Genome Atlast Project), 505 B-ALL and 101 T-ALL cases (data shared by Nordlund *et al.* Genome Biology. 2013). Copy number variation was inferred from methylation array data.
Results: Among 31 MPAL cases, 18 (58%) had myeloid-T and 13 (42%) had myeloid-B phenotype. Four cases had Philadelphia chromosome, 1 had 11q23 abnormality, and 8 had complex karyotype. MPAL had similar numbers of mutations (median 2 [range: 0-6]) with AML (median 3 [range: 0-7], P=0.79) or T-ALL (median 3 [range: 1-4], P=0.92) but had significantly higher number of mutations than B-ALL (median 0 [range: 0-4], P<0.001). Consistent with the mixed immunophenotypic features, MPAL had both AML-type and ALL-type mutations. However, *NPM1* mutation was specific to AML and was not found in MPAL cases. Myeloid-T and myeloid-B showed distinct patterns of somatic mutations. Genes in which mutations were enriched in myeloid-T than in myeloid-B included *DNMT3A* (33% *vs* 8%), *IDH2* (33% *vs* 8%), *NOTCH1* (39% *vs* 0%), *IL7R* (17% *vs* 0%), and *FBXW7* (6% *vs* 0%). Genes in which mutations were less frequently observed in myeloid-T than in myeloid-B included *RUNX1* (6% *vs* 46%), *ASXL1* (0% *vs* 23%), *TET2* (0% *vs* 15%), *SRSF2* (6% *vs* 23%), and *FLT3* (11% *vs* 23%). Myeloid-T and myeloid-B showed distinct patterns of promoter CpG methylation. Overall, myeloid-T had more hypermethylated CpG loci than myeloid-B in all different CpG locations (island, shore, shelf, and others). Genes that are essential in T-cell receptor (TCR) signaling (*CD3D*, *CD7*, *CD247*, *LCK*, *PRKCQ, CCR9, and TCL1A*) were differentially methylated and consequently differentially expressed between myeloid-T and myeloid-B. Copy number analysis showed that *DLL1*, one of the essential NOTCH pathway genes, was amplified and was overexpressed. RNA sequencing revealed several known translocations such as *NSD1-NUP98* and *KMT2A-MLLT4,* in addition to the novel translocations such as *FOXP1-DNAJC15*, *FLI1-IFT46*, and *ITPR2-ARID5B*. Unsupervised hierarchical clustering of all MPAL, AML, B-ALL and T-ALL by promoter CpG methylation pattern revealed that myeloid-T consistently showed similar methylation pattern with T-ALL, while myeloid-B showed random similarity with either B-ALL or AML.
Summary/Conclusions: MPAL is genetically heterogeneous disease and myeloid-T and myeloid-B shows distinct patterns of mutation landscapes, methylation and gene expressions. Therapy for MPAL may need to be personalized based on genomic profiles.

P551

THE EFFECTS OF EARLY INTENSIFIED INDUCTION CHEMOTHERAPY IN ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA COMPARED TO STANDARD ANTHRACYCLINE PLUS CYTARABINE 3+7 CHEMOTHERAPY

D.-H. Kwak[1,*], J.-H. Yoon[1], H.-J. Kim[1], S.-S. Park[1], S.-E. Lee[1], B.-S. Cho[1], K.-S. Eom[1], Y.-J. Kim[1], S. Lee[1], J.-W. Lee[1], W.-S. Min[1]
[1]Department of Hematology, Catholic Blood and Marrow Transplantation Center, Leukemia Research Institute, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Standard remission induction chemotherapy for adult acute myeloid leukemia (AML) which consists of anthracycline for 3 days plus cytarabine for 7 days was first introduced in 1970's and has been used for a long time. Several modification or intensification for this conventional regimen did not prove the effect for higher complete remission (CR) rate or lower relapse rate which led to superior overall survival (OS) rate.
Aims: We tried to find out possible benefit of early intensification of standard induction chemotherapy in adult AML patients.
Methods: This single center retrospective study enrolled 1195 adult AML patients from 2002 to 2013. All patients were initially treated with idarubicin (12mg/m^2) plus cytarabine (100mg/m^2) or BHAC (300mg/m^2) induction chemotherapy (3+7), and among them, 731 (61.2%) patients received additional early augmentation using cytarabine 3 days (3+10, n=363) or anthracycline 2 days plus cytarabine 3 days (5+10, n=368). The decision for augmentation was based on the follow-up BM blast counts on the 7th day of 3+7 chemotherapy; totally 3+10 for blast counts 5~20% and 5+10 for blast counts >20% (early intensified group). The rest 464 with blast counts < 5% finished with 3+7 regi-

men (standard group). Re-induction and consolidation therapy was performed according to a consistent strategy and post-remission therapy was mainly based on hematopoietic cell transplantation.

Results: Early intensified group was consisted of younger patients (median age, 37 years old [range 17-69] *vs* 45 years in 3+7 *vs* 43 years in 3+10 subgroup) and larger proportion of t(8;21) (n=102 [27.7%] *vs* 3+7 [n=33, 7.1%] *vs* 3+10 [n=47, 12.9%], *P*<0.001). Also, initial BM blast counts were higher in two intensified groups (73.3% in 5+10 and 70.1% in 3+10) compared to 3+7 subgroup (66.8%, *P*<0.001). Early death rate at 8 weeks was higher in patients older than 55 years (10.8% *vs* 3.7%, *P*<0.001) especially when they were treated with intensified chemotherapy (21.7% in 5+10 and 15.7% in 3+10 *vs* 6.3% in 3+7, *P*=0.038). CR rate after induction was higher in young patients especially in 3+10 subgroup (79.8%, *P*<0.001) and we also found that patients with favorable to intermediate-risk karyotype might benefit with intensified chemotherapy in the context of CR rate (79.7% *vs* 68.3% *P*<0.001), although final CR rates became similar after re-induction. Next, we found that pre-HCT relapse rate was lower in patients younger than 55 years (9.4% *vs* 18.0%, *P*=0.002) and favorable to intermediate-risk group (8.9% *vs* 20.2%, *P*<0.001) after intensified induction. In young patients with favorable to intermediate-risk karyotype, intensified group showed superior 5-year OS (55.0% *vs* 45.5%, *P*=0.010) and lower long-term relapse rate (32.2% *vs* 39.0%, *P*=0.084), but multivariate analysis revealed no effects for both OS and CIR. In patients older than 55 years, intensified group showed inferior 5-year OS (19.2% *vs* 22.8%, *P*=0.014) with higher early death rate (17.6% *vs* 6.3%, *P*=0.015), and multivariate analysis also showed intensified induction was related inferior OS (HR=1.89, 95%CI; 1.14-3.15, *P*=0.013).

Adverse-risk	23/79 (29.1%)	14/58 (24.1%)	13/68 (22.4%)	0.502

† Early death due to any cause (with or without aplasia) within 56 days after chemotherapy
†† Overall response rate (ORR, complete remission (CR)+ CR with incomplete recovery (CRi))
CR - PB, ANC > 1,000 (10^9/L), platelet > 100,000 (10^9/L), BM, blast < 5%. No extramedullary disease.
CRi - incomplete CR with persistence of cytopenia
1,2,3 Different numbers indicate significant difference between groups based on Tukey's multiple comparison test.
Abbreviation: Allo, allogeneic; Auto, autologous; PB, Peripheral blood; BM, Bone marrow; CTx ,chemotherapy; HCT, hematopoietic cell transplantation; NA, Not assessed

Summary/Conclusions: Our data revealed that intensified induction chemotherapy was not influential for poor-risk karyotype, while higher post-induction CR rate and low pre-HCT relapse was shown in young patients with favorable to intermediate-risk karyotype although it was not influential for final OS and CIR rate. In elderly patients, intensified induction chemotherapy was related with higher early death rate which finally showed poor OS.

P552

VARIANT FLT3 MUTATIONS CAN BE ERADICATED BY CYTARABINE/ANTHRACYCLINE/CRENOLANIB INDUCTION IN ADULT PATIENTS WITH NEWLY DIAGNOSED FLT3 (ITD/TKD) MUTANT AML

E. Wang[1,*], R. Stone[2], R. Collins[3], T. Agrawal[4], V. Urity[4], M. Tallman[5]
[1]Department of Medicine, Roswell Park Cancer Institute, Buffalo, [2]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, [3]The University of Texas Southwestern Medical Center, [4]Arog Pharmaceuticals, Inc., Dallas, [5]Department of Medicine, Leukemia Service, Memorial Sloan Kettering Cancer Center, New York, United States

Background: Patients (pts) with FLT3-internal tandem duplication (ITD) and FLT3-D835 mutant AML have a high relapse rate. These relapses are typically due to outgrowth of mutant FLT clones. Previously available PCR-based tests only checked for presence of FLT3-ITD and FLT3-D835/I836 mutations. Whole genome sequencing of 799 pediatric AML samples from COG trials have shown novel FLT3 variants in not only the tyrosine kinase domain but also the juxtamembrane (JM) and transmembrane domains in 7.6% of these samples (Tarlock *et al.* ASH 2015). Some of these mutations result in autophosphorylation of FLT3 and therefore may be oncogenic.

Aims: Identify novel FLT3 mutations in pts with FLT3 mutant AML and further investigate whether these novel clones are sensitive to induction chemotherapy plus a potent pan-FLT3 inhibitor, crenolanib.

Methods: Pts with newly diagnosed FLT3 mutant AML were enrolled and treated with cytarabine/anthracycline/crenolanib induction followed by high dose cytarabine (HiDAC) consolidation. Crenolanib 100mg TID was started on day 9 of induction and continued till next chemotherapy. Crenolanib was given following consolidation and allogeneic stem cell transplantation. Bone marrow samples were collected at baseline and at the time of remission assessment. Sequencing of the entire FLT3 gene was performed through FoundationOne Heme panel (n=18) and MSKCC multigene panel (n=5). Sequencing of exons 14,15,16, and 20 was performed through the Rapid Heme Panel at Dana-Farber Cancer Institution in additional 6 pts.

Results: Out of 29 newly diagnosed FLT3 mutant AML patients with full/partial FLT3 gene sequencing performed, 4 pts were found to have novel variant FLT3 mutations consisting of V491L, V592L, D593H, A680V, and N841I/T/K (Table 1). The majority of these novel mutations were located at the JM, kinase domain 1 and the activation loop (kinase domain 2). The allele fractions of these FLT3 variants ranged as high as 29% (higher than that of FLT3-ITD in pt3), suggesting that some of these clones may have been potentially driving clinical leukemia progression in some pts. All 4 pts had NPM1 mutations, and two also had DNMT3A mutations. All 4 pts achieved CR with full count recovery (3/4 pts achieved CR after just one cycle of cytarabine/anthracycline/crenolanib induction). The pt with FLT3-D835Yand N841T achieved a CR after cytarabine/anthracycline/crenolanib induction and one cycle of HiDAC consolidation. All pts became FLT3-ve and have remained FLT3-ve. 3 out of 4 pts received 1-4 cycles of HiDAC consolidation followed by crenolanib maintenance. Only one pt underwent allo SCT. With a median follow up of 13 months, one pt relapsed (at 8.4-month following treatment). This 61F pt was found to have FLT3-ITD, D593H and I836del FLT3 abnormalities at the time of diagnosis. A full FoundationOne gene panel done at the time of relapse, showed no residual FLT3 mutant clones.

Table 1.

Table 1: Novel FLT3 mutations in adult AML patients

Pt	Age/ Sex	FLT3 Mutations	Variant FLT3 Mutations	Other Mutations	Response after Induction 1	FLT3 Status after Treatment	Current Status
1	54/F	ITD	V491L (3%), V592A (1%), I836del (18%), N841I (8%)	NPM1, IDH2, SRSF2	CR	Negative	alive, in remission for ~12 months
2	61/F	ITD 9% (3 clones)*	D593H (9%), I836 del (3%)	NPM1, WT1	CR	Negative	alive, relapsed with non-FLT3 clones (*N-RAS* and *JAK3*)
3	54/F	ITD 13.5%	A680V (29%), N841K (16.2%)	NPM1, DNMT3A, CEBPA	CR	Negative (ITD)	alive, in remission for ~10.5 months
4	36/F	D835Y^	N841T (in trans with D835Y)	NPM1, DNMT3A, PTPN11	PR	Negative	alive, in remission for ~7.7 months

^TKD 49%

Summary/Conclusions: This abstract reports multiple novel variant FLT3 mutations in adult pts with newly diagnosed FLT3-ITD or FLT3-D835 mutant AML. The allelic burden of these FLT3 variant mutations can sometime be higher than that of FLT3-ITD. Detailed FLT3 analyses in this subset of pts suggests that crenolanib in combination with standard induction chemotherapy has the ability to eradicate variant FLT3 clones. All 4 pts treated with chemotherapy followed by crenolanib showed clearance of FLT3-ITD, TKD, as well as other novel variants. To achieve maximal clinical benefit, a potent pan-FLT3 inhibitor with the ability to inhibit ITD, D835, as well as other activating mutations maybe beneficial.

PATIENTS WITH ACUTE MYELOID LEUKEMIA WHO HAVE MUTATIONS IN IDH1 OR IDH2 RESPOND WELL TO INDUCTION CHEMOTHERAPY WITH "7+3" DESPITE THE PRESENCE OF COMPLEX KARYOTYPE OR FLT3-ITD

D.M. Gupta[1,*], D.S. Devlin[2], D.M. Tallman[2], D.E. Stein[2]

Background: Mutations in isocitrate dehydrogenase isoforms 1 and 2 (IDH1/IDH2) occur in 8-12% of patients with acute myeloid leukemia (AML). Mutant IDH enzymes catalyze the conversion of alpha ketoglutarate to beta hydroxyglutarate. Increased concentrations of intracellular 2-HG lead to histone hypermethylation and a block in cellular differentiation and may also lead to suppression of homologous recombination. Previous studies of outcomes in patients given induction chemotherapy are limited by the heterogeneity of induction regimens. In this study, we investigated the outcomes of patients given induction chemotherapy with daunorubicin and cytarabine (7+3), the most common regimen used in the United States.

Aims: To delineate the complete remission rate in AML patients with IDH1 or IDH2 mutations who receive standard 7+3 induction chemotherapy.
Methods: After receipt of IRB approval, an institutional database of genomic abnormalities in all patients with AML was queried for patients with IDH1 or IDH2 mutations between the years of 2010 and 2016. Pathology records of patients identified as having an IDH1/IDH2 mutation were reviewed to confirm the presence of an IDH mutation. After confirmation of IDH mutational status, all patients who received standard induction chemotherapy with 7+3 were included in this retrospective chart review.
Results: Between 2010 and 2016, 82 patients with *IDH1/IDH2* mutations who had been treated with "7+3" induction chemotherapy were seen at MSKCC. Of these, 33 (40.2%)had *IDH1* mutations and 49 (59.8%) had *IDH2* mutations. Of those with IDH2 mutations *IDH2 R140Q* mutations were present in 34 (69.3%)and *IDH2 R172K* mutations were present in 15 (30.6%). The median age of all patients treated was 63. 56 patients (68%) had *de novo* AML, 16 (20%) had AML with myelodysplasia related changes, 5(6%) had a a known prior history of MDS and 5 (6%) had therapy related AML. Nearly half of the patients (49%) had karyotypic abnormalities. Of the 82 patients who received induction chemotherapy with "7+3", 51 achieved a complete remission (CR) after 1 cycle and 16 after 2 cycles for a CR rate of 82%. The strongest predictor of response to induction chemotherapy was the presence of an NPM1 mutation. There was a trend towards decreased response to induction chemotherapy in patients with a complex karyotype (p=.079) that did not reach statistical significance. The presence of an IDH2 R172K mutation was predictive of non-response to one cycle of (7+3) of 7+3 but when two cycles of induction chemotherapy were given, response rates were equivalent to patients with R140Q mutations. Co-occurring mutations in FLT3 (ITD or TKD), DNMT3A or NRAS were not predictive of responses to induction chemotherapy.
Summary/Conclusions: Induction chemotherapy with 7+3 leads to a robust CR rate of 82% in patients with AML that harbor and IDH1 or IDH2 mutation. CR is not affected by IDH2 isoform (R172 or R140), although more patients with R172 mutations required two cycles of chemotherapy to achieve a remission. Karyotypic abnormalities did not influence the response to induction chemotherapy, nor did the presence of co-occurring FLT3-ITD, FLT3-TKD or NRAS mutations. For AML patients with IDH mutations who are eligible for induction chemotherapy "7+3" is a reasonable induction regimen regardless of the presence of FLT3 mutations, or karyotypic abnormalities.

Background: Treatment of Acute Myeloid Leukemia (AML) is limited to few different treatments in each clinical trial group guideline, but integrating current and previous guidelines, and clinical trial publications, there are up to 45 drug combination treatments among approved chemotherapy drugs in Europe and USA. There is a need for Precision Medicine (PM) tests to identify which of these different treatments maybe optimal for each individual patient, independently of where he/she lives.
Aims: To provide actionable data to improve disease management with existing treatments with a PM test to guide the hematologist among all possible treatments to achieve a CR.
Methods: AML bone marrow (BM) samples from adult patients were received at the laboratory within 24 hours from extraction and incubated for 48h in 96-well plates containing single drugs or combinations representing up to 45 different treatments that are currently given in the clinical practice. The analysis is performed in the automated flow cytometry PharmaFlow platform. 72 hours after the extraction of the sample, an encrypted report is sent to the hematologist before the patient begins treatment. Pharmacological responses were calculated using pharmacokinetic population models. Induction response was assessed according to the Cheson criteria (2003). Patients attaining a CR/CRi were classified as responders and the remaining as resistant, excluding early deaths. Final scores and treatments ranking is based on a therapeutic algorithm that integrates *ex vivo* activity; monotherapy dose responses quantified by the area under the curve (AUC) with limits such as Cmax values, and synergism calculated measuring 8 concentration ratios requiring consistency in their results in a 3D surface (so called alpha factor synergism). The PM Test attempts to identify at least one treatment, among all evaluated alternatives, predicted sensitive for each patient; conversely, if sensitive treatments can be identified the PM Test can provide the hematologist with valuable guidelines for individualized treatment.
Results: (Figure 1) The scoring method was tested using *ex vivo* results from samples obtained in an observational clinical trial with Spain´s PETHEMA group from a cohort of 123 samples from *de novo* diagnosed AML patients, treated with the standard PETHEMA 1st line guideline 3+7 with CYT+IDA. The score predicts sensitive patients with 90% accuracy. This accuracy can be compared with an independently derived 92% accuracy in identifying sensitive patients in a statistically significant clinical correlation study (EHA Poster 2016 Montesinos *et al.*). The score is a simplified version of such correlation algorithm. Both methods identify a similar % of all clinically sensitive patients (67% *vs* 71%).

However, the correlation is only valid for CYT-IDA while the PM Test is applied to up to 45 treatments. Any such treatment identified as sensitive means the PM Test can provides a valuable guideline to hematologists. This means the PM Test can suggest sensitive treatments for the vast majority of patients.

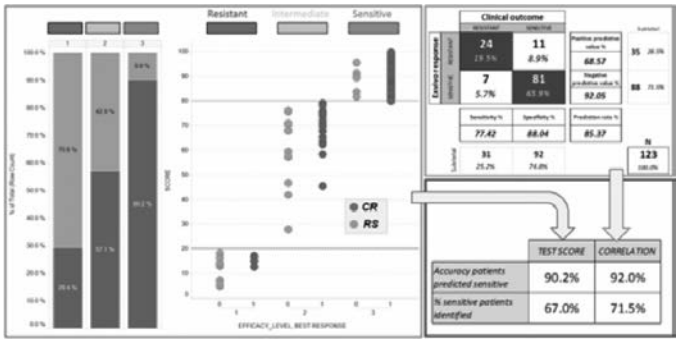

Figure 1.

Summary/Conclusions: We have developed a novel *ex vivo* PM test for induction treatment in AML patients to guide hematologists selecting the right treatment to achieve CR in individual patients leveraging up to 45 different validated chemotherapeutic regimes. Assuming a similar response rate for all these treatments, our test could estimate a net prediction for sensibility to AML treatment higher than 80% in 1st line. This PM Test will be evaluated in an interventional clinical trial on relapse/refractory patients that is expected to begin in the next few months in collaboration with the PETHEMA group from Spain.
